Sir William Dunn Reader in Biochemistry, Cambridge University, since 1922. Head of Genetical Department, John Innes Horticultural Institution since 1927. Contributor to *Journal of Physiology*; *Journal of Genetics*; etc. } Heredity.
- J. C. Smu. GENERAL JAN C. SMUTS, P.C., K.C., M.L.A.
Prime Minister of South Africa, 1919-24. Leader of the Opposition since 1924. Author of *The League of Nations, a Practical Suggestion*; *Holism and Evolution*. } Holism.

- J. Da. REV. JAMES DAVIES, M.A.
Formerly Head Master of Ludlow Grammar School and Prebendary of Hereford Cathedral. Translated classical authors for Bohn's "Classical Library." Author of volumes in Collins's *Ancient Classics for English Readers*. } Hesiod (*in part*).
- J. E. D. JUNE ETTA DOWNEY, B.A., M.A., PH.D.
Professor of Psychology, University of Wyoming, Laramie, Wyo. Author of *Graphology and the Psychology of Hand-Writing*; *Will-Temperament and Its Testing*; *Plots and Personalities*; *Creative Imagination*. } Handedness;
Handwriting (*in part*).
- J. E. H. R. JAMES ERNEST HELME ROBERTS, M.B., B.S., F.R.C.S.
Surgeon, with charge of out-patients, St. Bartholomew's Hospital, London. Senior Surgeon, Brompton Hospital for Consumption and Diseases of the Chest, London. } Heart and Lung, Surgery of.
- J. F. C. F. COLONEL JOHN FREDERICK CHARLES FULLER, C.B.E., D.S.O.
Military Assistant to the Chief of the Imperial General Staff. Chief General Staff Officer, Tank Corps, 1917-8. Formerly Chief Instructor, Camberley. Author of *Tanks in the Great War*; *The Reformation of War*; *Sir John Moore's System of Training*. } Hydaspes, Battle of the.
- J. F. M. JAMES FULLARTON MUIRHEAD, LL.D.
Editor of many of Baedeker's Guide Books. Author of *America, the Land of Contrasts*. } Huggenberger, Alfred.
- J. G. R. JOHN GEORGE ROBERTSON, M.A., PH.D.
Professor of German Language and Literature, University of London. Author of *History of German Literature*; *Schiller after a Century*; etc. } Heine, Heinrich (*in part*).
- J. H. D. J. H. DRIBERG.
Author of *The Lango: A Nilotic Tribe of Uganda*. } Hehe.
- J. H. F. JOHN HENRY FREESE, M.A.
Formerly Fellow of St. John's College, Cambridge. } Hesiod (*in part*).
- J. H. H. J. H. HUTTON, D.Sc., C.I.E.
Director, Ethnology, Assam. Deputy Commissioner, Naga Hills. Author of *The Angami Nagas*; *The Sema Nagas*, and many papers in *Journal of the Royal Anthropological Institute*; etc. } Head-Hunting.
- J. H. Hes. JOHN HENRY HESSELS, M.A.
Author of *Gutenberg: an Historical Investigation*. } Gutenberg, Johann.
- J. H. W. J. H. WALKER, A.M.E.
Superintendent of Central Heating, The Detroit Edison Company, Detroit, Mich. Co-author of *Heating and Ventilation*. } Heating and Ventilation.
- J. L. He. JOHN L. HERVEY.
Editor, *The Horse Review*, New York. Special writer on racing for the *Sportsman*, *The Thoroughbred Record*, *Daily Racing Form*. } Horse-Racing and Breeding
(*in part*).
- J. M. de N. J. M. DE NAVARRO, M.A.
Fellow of Trinity College, Cambridge. } Hallstatt.
- J. M. La. J. M. LANDIS, A.B., LL.B., S.J.D.
Professor of Legislation, Harvard Law School. Co-author of *The Business of the Supreme Court of the United States*. } Habeas Corpus (*in part*).
- J. M. M. JOHN MALCOLM MITCHELL, O.B.E., M.A., M.C., F.S.A.(SCOT.).
Secretary, Carnegie United Kingdom Trust. Vice-President, Library Association. Assistant Editor in Classics and Ancient History, 11th Edition, *Encyclopædia Britannica*. } Harem.
- J. Ne. JOSEPH NEEDHAM, M.A., PH.D.
Fellow of Gonville and Caius College and University Demonstrator in Biochemistry, Cambridge. Author of *Chemical Embryology*; etc. } Hopkins, Sir Frederick
Gowland.
- J. N. P. JOHN NORMAN PRING, M.B.E., D.Sc.
Head of Physical Chemistry Branch, Research Department, Royal Arsenal, Woolwich. Member of Council of Faraday Society since 1922. Author of a number of textbooks and publications of original research in scientific journals. } Hydrogen-Ion Concentration
(*in part*).
- J. S. Co. JAMES SUTHERLAND COTTON, M.A.
Editor of *The Imperial Gazetteer of India*. Hon. Secretary of the Egyptian Exploration Fund. Formerly Fellow and Lecturer of Queen's College, Oxford. Author of *India in the "Citizen" Series*. } Hastings, Warren (*in part*).
- J. Sp. JOHN SPARROW.
Of New College, Oxford. } Housman, Alfred Edward.
- J. Sz. JULIUS SZEKFÜ.
Professor of Hungarian History, University of Budapest. } Hungary (*in part*).
- J. T. M. JOHN TORREY MORSE, JR.
Author of *The Life and Letters of Oliver Wendell Holmes*. } Holmes, Oliver Wendell.
- J. T. S. JAMES THOMSON SHOTWELL, PH.D., LL.D.
Professor of History, Columbia University, New York. Director of Economics and History, Carnegie Endowment for International Peace. } History.
- J. V. B. JAMES VERNON BARTLET, M.A., D.D.
Professor Emeritus of Church History, Mansfield College, Oxford. Author of *The Apostolic Age*; etc. } Hebrews, Epistle to the.
- J. War. JAMES WARD, D.Sc., LL.D., F.B.A.
Formerly Professor of Mental Philosophy and Logic in the University of Cambridge. Fellow of Trinity College, Cambridge. Fellow of the New York Academy of Sciences. } Herbart, Johann Freidrich
(*in part*).
- J. We. JOHN WEATHERS, F.R.H.S.
Lecturer on Horticulture to the Middlesex County Council. Author of *Practical Guide to Garden Plants*; *French Market Gardening*; etc. } Horticulture (*in part*).
- J. W. F. JOHN WATSON FOSTER, A.M., LL.D.
Professor of American Diplomats, George Washington University, Washington. Formerly United States Secretary of State. Author of *Diplomatic Memoirs*; etc. } Harrison, Benjamin.

INITIALS AND NAMES OF CONTRIBUTORS

J. W. Fe.	J. WALTER FERRIER. Translated <i>George Eliot and Judaism</i> from the German of Kaufmann. Author of <i>Mottiscliffe</i> .	Heine, Heinrich (<i>in part</i>).
K. W. K.	KATHERINE W. KUMLER. Director of Home Economics, Skidmore College, Saratoga Springs, New York	Home Sewing.
L. A.	LASCELLES ABERCROMBIE, M.A. Professor of English Literature, University of Leeds. Formerly Lecturer in Poetry, University of Liverpool. Author of <i>Thomas Hardy, A Critical Study</i> ; <i>Theory of Poetry</i> ; <i>Idea of Great Poetry</i> ; etc.	Hardy, Thomas.
L. C. M.	SIR LEO CHIOZZA MONEY, F.R.STAT.S., F.R.G.S., F.Z.S. Author and Journalist. Member of the War Trade Advisory Committee, 1915-8. Parliamentary Secretary to the Ministry of Shipping, 1916-8. Chairman of the Tonnage Priority Committee, 1917-8. Editor of the Economic, Engineering and Industry section, 14th Edition, <i>Encyclopædia Britannica</i> .	Hadfields, Limited.
L. E. M.	L. E. MOFFATT. Managing Editor of <i>Electrical Merchandizing</i> , New York.	Household Appliances (<i>in part</i>).
L. H. Ba.	LIBERTY HYDE BAILEY, LL.D. Director, College of Agriculture, Cornell University, 1903-13. Editor, <i>Cyclopaedia of American Horticulture</i> .	Horticulture (<i>in part</i>).
L. J. S.	L. J. SPENCER, M.A., Sc.D., F.G.S., F.C.S., F.R.S. Keeper of Department of Mineralogy, Natural History Museum, South Kensington. Formerly Scholar of Sidney Sussex College, Cambridge, and Harkness Scholar. Editor of <i>The Mineralogical Magazine</i> .	Hyacinth, or Jacinth.
L. O. H.	LELAND OSSIAN HOWARD, Ph.D., M.D., LL.D., Sc.D. Principal Entomologist, United States Department of Agriculture, Bureau of Entomology, Washington. Author of <i>Mosquitoes, How They Live</i> ; <i>The Insect Book</i> .	Gypsy Moth; Harlequin Cabbage Bug.
L. Ri.	LOUIS RIPAULT. Private Secretary to the President of the Chamber of Deputies, France. Author of <i>Histoire du Canada</i> ; <i>Histoire des Etats-Unis</i> ; etc.	Herriot, Edouard.
L. S. R.	L. S. RICHARDSON, B.S. Assistant Chief, Press Service, United States Department of Agriculture, Washington.	Harvesting Machinery (<i>in part</i>).
L. T. H.	L. T. HOGGEN, D.Sc. Professor of Zoology, University of Cape Town, South Africa.	Homology.
Lz.	COUNT LUTZOW, LITT.D., Ph.D., F.R.G.S. Author of <i>Bohemia, an Historical Sketch</i> ; <i>The Historians of Bohemia</i> (Ilchester Lecture, Oxford, 1904); <i>The Life and Times of John Hus</i> ; etc.	Hussites.
M. C.	MAX CARY, D.LITT. Reader in Ancient History in the University of London. Secretary to the Classical Association, 1911-4.	Hellenism; Heraclius.
M. G.	MOSES GASTER, Ph.D. Chief Rabbi of the Sephardic Communities of England. Vice-President, Zionist Congress, 1898, 1899 and 1900. Ilchester Lecturer at Oxford on Slavonic and Byzantine Literature, 1886 and 1891. President, Folklore Society of England. Author of <i>History of Roumanian Popular Literature</i> ; <i>A New Hebrew Fragment of Ben Sira</i> ; <i>The Hebrew Version of the Secretum Secretorum of Aristotle</i> ; etc.	Gypsies (<i>in part</i>); Hasdeu.
N. F.	NORMAN FRENCH. Editor, <i>The Hardware Trade Journal</i> , London.	Hardware (<i>in part</i>).
N. G. G.	NICHOLAS G. GEDYE, O.B.E., B.Sc., M.INST.C.E. Consulting Civil Engineer. Formerly Chief Engineer, Tyne Improvement Commission. Served B.E.F. Lt.-Colonel (Late R.E.). Acting Director, Civil Engineer-in-Chief's Department, Admiralty. Chief Civil Engineer for Docks, Harbours and Inland Waterways, Ministry of Transport.	Harbours.
O. B.	OSWALD BARRON, F.S.A. Editor of <i>The Ancestor</i> , 1902-5.	Heraldry.
P. Al.	PAUL DANIEL ALPHANDÉRY. Professor of the History of Dogma, Ecole Pratique des Hautes Etudes, Sorbonne, Paris. Author of <i>Les Idées morales chez les hétérodoxes latines au début du XIII^e Siècle</i> .	Humiliati.
P. Ge.	PIETER GEYL, LITT.D. Professor of Dutch History and Institutions, University of London.	Holland (<i>in part</i>).
P. H.	PETER HENDERSON. Formerly Horticulturist, Jersey City and New York. Author of <i>Gardening for Profit</i> ; <i>Garden and Farm Topics</i> .	Horticulture (<i>in part</i>).
P. H. P.-S.	PHILIP HENRY PYE-SMITH, M.S., F.R.S. Formerly Consulting Physician to Guy's Hospital, London and Vice-Chancellor of the University of London. Joint-author of <i>A Text Book of Medicine</i> ; etc.	Harvey, William (<i>in part</i>).
P. McC.	PRIMROSE MCCONNELL, B.Sc., F.G.S. Member of the Royal Agricultural Society. Author of <i>Diary of a Working Farmer</i> .	Hay (<i>in part</i>).
P. M. R.	P. M. ROXBY, M.A. Professor of Geography in Liverpool University	Hongkong.
P. W. Z.	P. W. ZIMMERMAN, M.S., Ph.D. Scientific Research at the Boyce Thompson Institute for Plant Research, Yonkers, N. Y. Author of <i>Vegetative Plant Propagation</i> .	Horse Chestnut.
P. Z. C.	MAJOR-GENERAL SIR PERCY Z. COX, G.C.M.G., G.C.I.E., K.C.S.I. Acting British Minister to Persia, 1918-20. High Commissioner in Mesopotamia, 1920-3. Secretary, Foreign Department, Government of India, 1914. Consul and Political Agent, Muscat, Arabia, 1899-1904.	Hormuz.

W. S. F.	WILLIAM SCOTT FARREN, M.B.E., M.A. Consultant in Aeroplane Design. Lecturer in the Engineering Department, Cambridge University and at the Royal College of Science, London.	Helicopter.
W. S. L.	W. S. LEWIS. Professor of Geography, University College, Exeter.	Hungary (in part).
W. S. L.-B.	WALTER SYDNEY LAZARUS-BARLOW, B.A., M.D., F.R.C.P. Member of the Cancer Committee, Ministry of Health. Formerly Professor of Experimental Pathology, Middlesex Hospital Medical School, London University. Author of <i>A Manual of General Pathology; Elements of Pathological Anatomy and Histology for Students</i> . Editor of the Medicine section, 14th Edition, <i>Encyclopædia Britannica</i> .	Hospital (in part).
W. Sp.	WILLIAM SPRY. Late Commissioner of the General Land Office, Department of the Interior, Washington. Formerly Governor of Utah.	Homestead and Exemption Laws.
W. Tho.	WALLACE THOMPSON, B.Sc., LITT.D. Editor-in-Chief of <i>Ingenieria Internacional</i> , (New York). Fellow of the Royal Geographical Society. Author of <i>The People of Mexico; Trading with Mexico; The Mexican Mind; Rainbow Countries of Central America</i> .	Havana; Honduras.
W. T. Sa.	W. T. SAXTON, M.A. Lecturer on Botany, University of Reading.	Gymnosperms.
W. v. Bud.	WOLFGANG VON BUDDENBROCK-HETTERSDOFF. Professor of Zoology, University of Kiel. Director of the Zoological Institute and Museum, Kiel.	Hearing, Sense of.
W. W.	WILLISTON WALKER, PH.D., D.D. Formerly Professor of Church History, Yale University. Author of <i>History of the Congregational Churches in the United States; The Reformation; John Calvin</i> .	Hopkins, Samuel.
W. Wal.	WILLIAM WALLACE. Philosopher. Late Fellow and Librarian of Merton College, and White's Professor of Moral Philosophy, Oxford University. Author of <i>The Logic of Hegel</i> ; etc.	Hegelian Philosophy (in part).
W. W. P.	W. WYATT PAINE, J.P., F.S.A. Author and Editor of numerous legal textbooks.	Husband and Wife (in part).
X.	Initial used for anonymous contributors.	

THE ENCYCLOPÆDIA BRITANNICA FOURTEENTH EDITION

VOLUME II GUNNERY TO HYDROXYLAMINE

GUNNERY, NAVAL. It is no easy matter to hit a moving target at sea, with a gun mounted upon an unstable platform which is also moving in relation to the target. Two elements must be accurately known to obtain a hit. Firstly, the correct range, so that the gun, when fired, shall be at the proper elevation to throw its shell to that distance and, secondly, the deflection, or lateral correction, to allow for the wind and the movement of the target whilst the shell is in flight. A gunlayer firing a single gun at short range can follow the path of his shot and see it strike the water or target, and can correct his sights so that the next shot will hit. Under battle conditions, with a number of guns firing, this becomes a sheer impossibility for anyone stationed at the guns. Hence the necessity for controlling the gunfire of a ship from a position remote from the guns themselves. The control officer is stationed high up in the ship, where he is in the best position to see the fall of the shot and where he has all the available information for estimating the hitting range and arrangements for communicating it to the guns. The gunlayers keep their guns laid upon the target and fire on the command of the control officer.

Let us consider the simple case of a ship firing at a target at a range of about 10,000 yards. The range is obtained by the rangefinder, and certain corrections, which will be explained later, are applied to the rangefinder range to obtain the "gun range" which, with the estimated deflection, is passed to the guns. As the target and the firing ship are both moving, the range must be changing at a certain rate: this "rate of change of range" is estimated and applied to the gunsights at set intervals. The control officer fires a salvo and watches the fall of shot. He makes a spotting correction in range and deflection, calculated to get the next salvo to fall upon the other side of the target to the first one. If this happens he halves his original spotting correction and applies it in the opposite direction and fires again. This third salvo should fall close around the target, and if the rate of change of range has been correctly estimated, subsequent salvos will continue to hit. This is a very simple case of a bracket system which is used, in one form or another, by all control officers.

Corrections.—The corrections, which must be applied to the rangefinder range in order to obtain the hitting or gun range, are due to (1) the differences in muzzle velocity of individual guns, (2) the effect upon muzzle velocity of the

charges, (3) the direction and force of the wind, and (4) the height of the barometer and thermometer. The first two are usually applied direct on to the sights of each individual gun and remain more or less constant for any one day. The last two factors vary from hour to hour and are applied as a correction to the rangefinder readings. The rate at which the range is changing is another variable factor, since it depends upon the bearing between the ship and the target, which is constantly changing. The same applies, in a lesser degree, to the deflection, and constant corrections in both rate and deflection are necessary to maintain hitting after it is established.

Thus there are many problems to be solved, even in the simple case of firing at a target at 10,000 yards. Battle ranges have now been extended up to 20,000 yards and more, and as the range increases the problems with which the control officer is faced become much more complicated. At long ranges the observation of the fall of shot becomes extremely difficult, and as the range increases errors caused by the roll, yaw and pitch of the ship become accentuated. The shells in their flight reach a very high altitude and the wind and atmospheric conditions in the upper air cannot be known with sufficient accuracy to enable corrections to be made. The effects of the variations in the muzzle velocity, due to the wear of the guns, to changes in temperature of charges and to more obscure causes, become more pronounced. Range observation, even with the most perfect instruments and with the best trained observers, becomes less accurate as the range increases. It is therefore a matter of great difficulty to make an accurate forecast of the initial gun range and deflection. It has become the practice to obtain the hitting range by a process of "trial and error," using the gun as its own rangefinder with a large bracket system, after obtaining what assistance is possible from the instruments of observation. This can be done as long as the fall of shot can be observed, but becomes impossible as soon as this condition ceases to exist. Aircraft are now used to assist in the observation of fire at extreme ranges, and it is in this direction that future developments may be expected.

THE MECHANISM OF FIRE CONTROL

The installation used for fire control was intricate in the years before 1914, and war experience has made necessary the addition of further complications. The perfecting of the fire control organization of any ship is the most important item in making her into an efficient fighting unit, and it requires painstaking exercise

lasting over many weeks. Little can be said of the details of the various instruments used. Each navy regards its installation as confidential, and the functions, and even the existence of some instruments, are kept as secret as possible. The main problems are, however, the same for all and may be divided into three parts: (1) the communications between the control stations and the guns; (2) the apparatus for obtaining the hitting range and deflection and for keeping them both correct; (3) the arrangements for firing the guns and for observing the fall of shot.

Communications.—Communication must be maintained between the observing stations aloft, the principal control position, the transmitting station and the gun positions. As most of the information is only of value at the moment of transmission and loses its significance if delay occurs, communications must be rapid and sure, and hence several lines usually exist between important stations. All lines of communication are generally concentrated into the transmitting station, which is situated well below the armoured deck in the quietest place that can be selected. Voice-pipes are used between stations that are moderately close together. A voice-pipe must be as straight as possible and there are well defined limits of length for each diameter of pipe, beyond which the acoustic properties are lost. The telephone is used between all stations and there is usually a telephone exchange, in or near the transmitting station, solely for the use of the fire control organization. The telephone transmitters and receivers are specially designed for use by operators who have other duties to perform, or for instruments that are exposed to the weather or the blast of the guns. Electro-mechanical transmitters and receivers are used for passing ranges, deflection, bearing, orders and other information of a standard character. There are many different patterns of these instruments, those most commonly used in all navies being the Barr and Stroud "step by step," the Vickers "counter" and the "follow the pointer" types.

The Transmitting Station.—In the transmitting station are situated the majority of the calculating instruments, and to this position are passed the results of all observations of range, etc. The functions of most of these instruments are confidential. Broadly, they consist of arrangements for deducing the course and speed of the enemy from the data available and for calculating from this the rate of change of range and the deflection to be applied to the gun sights. In the British service the Dreyer calculating table is in general use and to this, the details of which are secret, constant improvements are being made. In all navies some form of calculating apparatus is used, and there are a number of patented sets of instruments, notably the Argo and the Ford, which are designed for this purpose.

Rangefinders.—The Barr and Stroud coincidence rangefinder is the one most commonly used by all navies, and this instrument forms the equipment of the British fleet. In a capital ship there are at least six large rangefinders, and the number and size of the instruments are reduced proportionately in smaller ships. The observations of each instrument are transmitted electrically to the transmitting station, where apparatus exists for obtaining a mean of all the observations, thus giving what is called the "mean rangefinder range." To this are applied the corrections for the density of the air, the effect of wind, the change of range during the flight of the projectile and for several other variables. (See also RANGEFINDER, NAVAL.)

Change of Range Calculators.—To obtain the rate at which the range is changing at any moment involves the solution of two triangles, the functions of which are the course and speed of the firing ship and the bearing, course and speed of the target ship. The first two of these are known, the third is easily observable, but the last two can only be obtained by calculation or be judged approximately by observation. The speed of the target must always be guessed in the first instance, and instruments known as inclinometers are used whereby the angle between the line of fire and the course of the target ship can be observed with fair accuracy. There are several types of change of range calculators: that used in the British service is the Dumaresque, in which the elements are set graphically and the resulting rate of change of range is read off in "yards per minute," which is what is required.

Range Clocks.—Some type of clock, which can be set to run at the rate at which the range is changing, is used by all navies. In the British service the Vickers clock is used. This consists of a powerful clockwork escapement, driving a large pointer round a clock face, the perimeter of which is graduated in yards. A method of altering the speed of the pointer is fitted, so that it can be made to run at speeds of 0 to 2,000 yards per minute in either direction (*i.e.*, increasing or decreasing range). Arrangements are made for large corrections in range to be made to the perimeter of the clock without interfering with the motion of the pointer, so that the clock can always be run at the range that it is desired to transmit to the guns.

Deflection Calculators.—To obtain the correct deflection for hitting at long range is a difficult matter. There are many types of deflection calculators which give an approximation to the deflection, but all these instruments have their limitations. Allowance can be made for the wind at the firing ship, but at long range the wind effect at the target may be entirely different. Also, the direction and force of the wind in the upper air through which the projectile passes are unknown factors. The practice is to calculate the proper setting as near as is possible and then to correct it by observation of the fall of shot. Correct deflection is of the greatest importance whilst ranging, for at long ranges, unless the shot fall in line with the target it is impossible to tell whether they are short or over.

Bearing Indicators.—Azimuth plates are carried in the control positions with telescopes mounted upon them. The zero is fixed in the fore and aft line of the ship and the bearing of any object with reference to this can be readily observed. In the Evershed type, used in the British navy, the bearings are transmitted electrically and the instruments afford a ready means of indicating the correct target to the guns, but this system, even where still fitted, is now secondary to the Director (*see below*).

OBSERVING AND FIRING THE GUNS

When the ranges were moderate it was the practice to use a single gun for ranging, before opening fire with the whole broadside. But no two guns can be built that will always shoot alike, and the differences between individual guns become accentuated at long ranges, owing to a variety of causes. This leads to a spread or "pattern" when a number of guns of the same size are fired at the same elevation. The "spread of the salvo," as it is called, can be reduced by making careful adjustments, but it can never be eliminated entirely, even if there are no errors in laying the guns. The spread can, however, with care and training of the personnel, be made an approximately constant quantity, and this quantity is known to the control officer of each individual ship. It is now the general practice to range with a salvo of several guns, usually half the broadside, and to continue firing alternate salvos, of an equal number of guns. The object of the control officer is, by using some form of bracketing system, to bring the mean point of impact of his salvos on to the target. This is termed a "straddle," that is, some shots over and some short, the maximum hitting effect being obtained.

Director Firing.—All modern navies have adopted some form of master sight or director, whereby all guns can be fired by a single layer. This system of firing has many advantages, chief amongst which are the elimination of smoke interference, the reduction of personal errors and the simplification of control.

In the British navy the director installation invented by Admiral Sir Percy Scott is used. This consists of a director sight situated well away from the guns themselves and carried in a mounting which can be trained and elevated in the same manner as a gun mounting. The motion of the director mounting is transmitted electrically to the pointers of training and elevation receivers at the guns. On these receivers are mechanical pointers geared to the training and elevating gear of the turret or gun. The gun is moved in training and elevation so that the mechanical pointers are kept in line with the electric ones worked by the director mounting. The guns thus follow the motions of the director or master sight and are laid at the desired elevation and training. The gun range and deflection are set upon the director

sight and the director telescope is laid upon the target in the same manner as a gunsight. The firing circuits of all guns are brought to a single trigger at the director sight so that all guns can be fired simultaneously by the director layer.

This brief description indicates the principle upon which the director is worked, but in practice there are many complications. Corrections have to be made for the relative positions and levels of the different gun mountings and for many other matters. The installation is intricate, but it has withstood the acid test of prolonged war service. In capital ships there are, as a rule, two director sights, one mounted aloft and one just above the level of the guns, which can be used alternatively for the main armament. A director is also fitted for use with the secondary armament.

Squadron Firing.—In the foregoing the gun control of a single ship only has been dealt with, but under modern battle conditions it often happens that more than one ship will engage the same target. When this occurs, unless there is some pre-arranged organization, confusion will arise owing to the spotting officer taking the fall of the other ship's salvoes for his own. Therefore a pair of ships firing at the same target will generally fire a salvo or pair of salvoes alternately, each waiting upon the other. A squadron of four ships may fire together at the same target, the fire being controlled by the control officer of the leader, who orders the gun range at which each ship shall fire. He receives the results of observations of the fall of shell from his own and the other ship's spotting officers or from aircraft. Such practice necessitates high organization and an intimate intercommunication between the control officers, which has been made possible by wireless telegraphy. The object of the squadron control officer is the same as that of the control officer of a single ship, that is, to bring the mean point of impact of the fire of the whole armament of the squadron as near the target as possible, for then only can he be sure that he is getting the maximum hitting effect. In view of the extreme ranges at which future actions at sea will be fought, it appears certain that fire tactics will tend to develop in the direction of concentrated fire by pairs of ships or by squadrons, aided by observation from the air.

(S. T. H. W.)

GUNPOWDER is a mixture of saltpetre, sulphur and charcoal in such proportions that, when a part is heated to a certain temperature, combustion takes place with great rapidity through the bulk in contact and an explosive effect is produced. It may be more correct to speak of the introduction than of the invention of gunpowder, for Friar Roger Bacon chanced upon it as the result of obtaining nearly pure nitre. (See EXPLOSIVES.) The honour has, however, also been associated with the name of Berthold Schwartz, a German monk, of whom O. Guttman writes (*Monumenta pulveris pyrii*, p. 6, 1904): "Berthold Schwartz was generally considered to be the inventor of gunpowder, and only in England has Roger Bacon's claim been upheld, though there are English writers who have pleaded in favour of Schwartz. Most writers are agreed that Schwartz invented the first fire-arms, and as nothing was known of an inventor of gunpowder it was perhaps considered justifiable to give Schwartz the credit thereof. There is some ambiguity as to when Schwartz lived. The year 1354 is sometimes mentioned as the date of his invention of powder, and this is also to be inferred from an inscription on the monument to him in Freiburg. But considering there can be no doubt as to the manufacture in England of gunpowder and cannon in 1344, that we have authentic information of guns in France in 1338 and in Florence in 1326, and that the Oxford ms. *De officiis regum* of 1325 gives an illustration of a gun, Berthold Schwartz must have lived long before 1354 to have been the inventor of gunpowder or guns." In Germany also there were powder-works at Augsburg in 1340, in Spandau in 1344, and Liegnitz in 1348. An indenture first published by Sir N. H. Nicolas (*History of the Royal Navy*, 1846) and later by Col. Brackenbury (*Proc. R. A. Inst.*, 1865), stated to be of 1338, contains references to small cannon as in the stores of the Tower, in London, and also mentions "a small barrel of gunpowder." In the Record Office, in London, also are trustworthy accounts of the purchase

of ingredients of powder (starting with the year 1345) and of the shipping of cannon to France, and in 1346 Edward III. appears to have ordered all the available sulphur and saltpetre to be bought up for him. The manufacture of gunpowder seems to have been carried on as a Crown monopoly about the time of Elizabeth, and regulations respecting gunpowder and nitre were made about 1623 (James I.). Powder-mills were probably in existence at Waltham Abbey, England, about the middle or towards the end of the 16th century.

Roger Bacon, in his anagram, gives the first real recipe for gunpowder (see Hime, *Gunpowder and Ammunition*, 1924), viz., saltpetre 41.2, charcoal 29.4, sulphur 29.4%. Dr. John Arderne of Newark, who began to practise about 1350 and was later surgeon to Henry IV., gives a recipe (Sloane mss. 335,795)—saltpetre 66.6, charcoal, 22.2, sulphur 11.1%, "which are to be thoroughly mixed on a marble slab and then sifted through a cloth." This powder is nominally of the same composition as one given in a ms. of Marcus Graecus, but the saltpetre of his formula was undoubtedly answerable for the difference in behaviour of the two compositions. Roger Bacon had not only refined and obtained pure nitre, but had appreciated the importance of mixing thoroughly the components of the powder. Most if not all the early powder was a "loose" mixture of the three ingredients, and the most important step in connection with the development of gunpowder was undoubtedly the introduction of wet mixing or "incorporating." Whenever this was done the improvement in the product must have been immediately evident. In the damp or wetted state pressure could be applied with comparative safety during the mixing. The loose powder mixture came to be called "serpentine"; after wet mixing it was more or less granulated or corned and was known as "corned" powder. Corned powder seems to have been gradually introduced; it is mentioned in the *Fire Book* of Conrad von Schöngau (1429). It would seem that corned powder was used for hand-guns or small arms in the 15th century, but cannon were not made strong enough to withstand its explosion for quite another century (Hime). According to the same writer, in the period 1250–1450, when serpentine only was used, one powder could differ from another in the proportion of the ingredients; in the modern period, say 1700–1886, the powders in use (in each state) differed only as a general rule in the size of the grain, whilst during the transition period, 1450–1700, they generally differed both in composition and size of grain. Corned or grained powder was adopted in France in 1525, and in 1540 the French utilized an observation that large-grained powder was the best for cannon and restricted the manufacture to three sizes of grain or corn, possibly of the same composition. Early in the 18th century two or three sizes of grain and powder of one composition appear to have become common. The composition of gunpowders used in different countries at different times is illustrated in the following tables:

English Powders (Hime)

	c. 1250	1350	1560	1647	1670	1742	1781
Saltpetre	41.2	66.6	50.0	66.6	71.4	75.0	75.0
Charcoal	29.4	22.2	33.3	16.6	14.3	12.5	15.0
Sulphur	29.4	11.1	16.6	16.6	14.3	12.5	10.0

Foreign Powders (Hime)

	France	Sweden	Germany	Denmark	France	Sweden	Germany
	1338	1560	1595	1608	1650	1697	1882
Saltpetre	50	66.6	52.2	68.3	75.6	73	78
Charcoal	25	16.6	26.1	23.2	13.6	17	19
Sulphur	25	16.6	21.7	8.5	10.8	10	3

The last column in the preceding table represents brown or coco-powder for large charges in guns. The charcoal involved is not burnt black but is roasted until brown, and is made, not from wood, but from some variety of straw. When reasonably pure, none of the ingredients of gunpowder absorbs any material quantity of moisture from the atmosphere, and only the nitre is a

soluble substance. The three substances were often mixed dry, just before being required; since saltpetre is considerably heavier than sulphur or charcoal, it would tend to separate out towards the bottom of the containing vessel and hence, with dry mixing, the proportions of the three ingredients would alter on carriage. Saltpetre and sulphur are chemical individuals and therefore, if pure, are always of the same composition, but this is not the case with charcoal—its composition, rate of burning, etc., depend not only on the nature of the woody material from which it is made, but quite as much on the temperature and time of heating employed in the making (see CHARCOAL). The woods from which it is made contain carbon, hydrogen and oxygen, and the last two are never thoroughly expelled in charcoal-burning. If they were, the resulting substance would be of no use for gun-powder: 1-3% of hydrogen and 8-15% of oxygen generally remain in charcoals suitable for gunpowder. A good deal of the fieriness and violence of explosion of a gunpowder depends on the mode of burning of the charcoal, as well as on the wood from which it is made.

Properties of Ingredients.—Charcoal, the chief combustible in powder, must burn freely, leaving as little ash or residue as possible, and it must be friable and grind into a non-gritty powder. The sources from which powder charcoal is made are dogwood (*Rhamnus frangula*), willow (*Salix alba*) and alder (*Betula alnus*). Dogwood is mainly used for small-arm powders which burn more rapidly than those from willow, etc. The wood after cutting is stripped of bark and allowed to season for 2 or 3 years. It is then picked to uniform size and charred for 5 to 7 hours in cylindrical iron cases or slips, which can be introduced into slightly larger cylinders set in a furnace. The slips are provided with openings for the escape of gases. The rate of heating as well as the temperature attained have an effect on the product, a slow rate of heating yielding more charcoal, and a high temperature reducing the hydrogen and oxygen in the final product. When heated for 7 hours to about 800° C to 900° C, the remaining hydrogen and oxygen amount to about 2% and 12% respectively. After heating, the slips are placed in a larger iron vessel, where they are kept comparatively air-tight until quite cold. The charcoal is then sorted, stored for some time, and then ground, the powder being sifted on a rotating reel or cylinder of fine mesh copper-wire gauze. The sifted powder is again stored for some time in closed iron vessels before use.

Sicilian sulphur, which is most generally employed for gunpowder, is purified by distillation, melting and moulding. It is afterwards ground into a fine powder and sifted as in the case of charcoal.

Manufacture.—During the mixing of the ingredients in the incorporating mill each batch is sprayed with water until the required amount has been added, and the sprays are so arranged that at the least sign of incipient firing in one mill, the contents of all the mills are immediately drenched. The milled cake is then reduced to a meal by gun-metal rollers regulated so that the pressure at any point nowhere exceeds 56 lb. per sq.in., thus avoiding dangerous friction. The meal is placed in a hydraulic press giving ultimately about 400 lb. per sq.in., and the ebonite plates used in the press are earthed in order to avoid accumulation of static electricity. The cakes are then trimmed down slightly since the outer layers are not so compressed as the inner parts. The pressed cake is grained or corned by passing down through inclined rollers, and is then screened. The material passing a 10-mesh and retained by a 20-mesh sieve is used for small-arm powders (R.F.G. or R.F.G.²), whereas the larger (10-mesh) and smaller (powdery) grains are returned to the hoppers or the incorporating mill, respectively, for further treatment.

The grains are freed from dust by being revolved in slightly tilted frames covered with 20-mesh gauze. They are then polished in order to diminish the tendency to absorb moisture—the process also increases the density. This is effected by rotation for 5-10 hours in large drums, the friction producing a brilliant glaze without the use of graphite in this type of powder. Other powders are run for shorter periods with about 1 oz. of graphite per 100 lb. of powder. The powders are placed in open-work shelves in a drying room heated by steam to about 40° C, the

moist air being carried off by efficient ventilators. Even and slow drying is best, for rapid drying tends to crack the grains; the time required is from 1 to 6 hours, depending on the size of grain and the moisture content. In this process the powder is rotated in long, horizontal, cylindrical wooden frames covered with canvas, whereby it is freed from the dust produced in drying and given a final glaze. At several stages in the manufacture, the various batches are mixed or "blended" in order to produce as uniform a product as possible.

The following data are approximate values for average powders and do not apply to powders of special composition for particular purposes, such as mining powders. According to Noble and Abel, 1 gr. of dry powder produces 720-800 gram-calories of heat on explosion, attaining a temperature of about 2,100° C, and giving 200-300 cu.-cm. of permanent gases (i.e., gases which do not condense to liquids on cooling to the ordinary temperature). The composition of these permanent gases (percentage by volume) is roughly:

Carbon dioxide	50	Sulphuretted hydrogen	3
Carbon monoxide	10	Hydrogen	2
Nitrogen	35	Methane and oxygen	traces

The composition of the dry solid residue (percentage by weight) is approximately:

Potassium carbonate	56	Potassium thiocyanate	0.5
Potassium sulphate	16	Potassium nitrate	0.2
Potassium sulphides	25	Charcoal and ammonium carbonate traces	
(mono- and poly-)			

Variations in conditions of burning may alter the foregoing proportions very appreciably.

GUNPOWDER PLOT, the name given to a conspiracy for blowing up King James I. and the parliament on Nov. 5, 1605. Organized as a reply to the anti-Roman Catholic laws, which, after a temporary relaxation, were being applied by James with renewed vigour, it originated at a meeting, probably in Jan. 1604, at a house in Lambeth, between Robert Catesby, Robert Winter his cousin, and John Wright. Later, several other persons were included in the plot, Winter's brother Thomas, Thomas Percy, John Grant, Ambrose Rokewood, Robert Keyes, Sir Everard Digby, Francis Tresham, a cousin of Catesby, and Thomas Bates, Catesby's servant, all, with the exception of the last, being men of good family and all Roman Catholics. Father Greenway and Father Garnet, the Jesuits, were both cognizant of the plot. Guy Fawkes was brought over from Flanders in April 1605. In March a vault immediately under the House of Lords was hired by Percy and 36 barrels of gunpowder (amounting to about 1 ton 12 cwt.), concealed there under coal and faggots. The preparations being completed in May the conspirators separated.

On Oct. 26 Lord Monteaule, a brother-in-law of Francis Tresham, who had engaged in Romanist plots against the government, but who had given his support to the new king, was seated at supper at Haxton when the following letter was brought to him: "My lord, out of the love I bear to some of your friends, I have a care for your preservation. Therefore I would advise you, as you tender your life, to devise some excuse to shift of your attendance

THE GUNPOWDER PLOT, 1605, AS REPRESENTED IN AN OLD PRINT
James I. is seen opening Parliament. Guy Fawkes stands below, at the entrance to the cellar, with lighted taper ready to fire the barrels of gunpowder. The Devil is at his side with bellows. An angel accompanies the discoverer of the plot, who is shown with lighted lantern. The scene is purely imaginative, since the plot was discovered two days before Parliament opened

of this Parliament, for God and man hath concurred to punish the wickedness of this time. And think not slightly of this advertisement, but retire yourself into your country, where you may expect the event in safety, for though there be no appearance of any stir, yet I say they shall receive a terrible blow, the Parliament, and yet they shall not see who hurts them. This counsel is not to be contemned, because it may do you good and can do you no harm, for the danger is past as soon as you have burnt the letter: and I hope God will give you the grace to make good use of it, to whose holy protection I commend you."

The authorship of the letter has never been disclosed or proved, but all evidence seems to point to Tresham and to the probability that he had some days before warned Monteaule and agreed with him as to the best means of making known the plot and preventing its execution, and at the same time of giving the conspirators time to escape (see TRESHAM, FRANCIS).

Monteaule at once showed the letter to Salisbury and other ministers, but the cellar under the House of Lords was not searched till Nov. 4. The whole plot was then discovered; Fawkes was arrested and tortured, while Catesby and others fled into the country, rejoining each other in Warwickshire, as had been agreed in case the plot had been successful. Catesby, who with some others had covered the distance of 80m. between London and his mother's house at Ashby St. Legers in eight hours, informed his friends in Warwickshire of the failure of the plot, but succeeded in persuading Sir Everard Digby, by an unscrupulous falsehood, further to implicate himself in his hopeless cause by assuring him that both James and Salisbury were dead. They failed to rally any of the support that they had expected from the countryside, and their small party was run to earth by the sheriff at Hewell Grange on Nov. 8. Catesby, Percy and the two Wrights were killed, Winter and Rokewood wounded and taken prisoners with the men who still adhered to them. In all eight of the conspirators, including the two Winters, Digby, Fawkes,

Rokewood, Keyes and Bates, were executed, while Tresham died in the Tower. Of the priests involved, Garnet was tried and executed, while Greenway and Gerard succeeded in escaping. The allegation that the whole affair was an *agent-provocateur's* plot for which Salisbury was responsible is now generally regarded as baseless.

In England, the anniversary of the discovery of the Gunpowder plot is still celebrated on Guy Fawkes' day (Nov. 5) by bonfires, fireworks, and the carrying of "guys" through the streets.

BIBLIOGRAPHY.—The great controversy of last century concerning the nature of the plot can be followed in: *What was the Gunpowder Plot?* by John Gerard, S.J. (1897); *What the Gunpowder Plot was*, by S. R. Gardiner (a rejoinder) (1897); *The Gunpowder Plot . . . in reply to Professor Gardiner*, by John Gerard, S.J. (1897); *Thomas Winter's Confession and the Gunpowder Plot*, by John Gerard, S.J. (with facsimiles of his writing) (1898); *Eng. Hist. Rev.*, iii. 510 and xii. 791; *Edinburgh Review*, clxxxv. 183; *Athenaeum*, 1897, ii. 149, 785, 855; 1898, i. 23, ii. 352, 420; *Academy*, vol. 52, p. 84; *The Nation*, vol. 65, p. 400. See also: D. Jardine, *The Gunpowder Plot* (1857); the official account, *A True and Perfect Relation of the Whole Proceedings against the late most Barbarous Traitors* (1606), and the collection of letters and papers in the State Paper Office called the *Gunpowder Plot Book* (1819).

GUNTER, EDMUND (1581–1626), English mathematician, of Welsh extraction, was born in Hertfordshire in 1581. He was educated at Westminster school, and in 1599 was elected a student of Christ Church, Oxford. He was professor of astronomy at Gresham college from 1619 until his death on Dec. 10, 1626. With Gunter's name are associated several useful inventions, descriptions of which are given in his treatises on the *Sector*, *Cross-staff*, *Bow*, *Quadrant* and other Instruments. In 1620 he published his *Canon triangulorum*. There is reason to believe that Gunter was the first to discover (in 1622 or 1625) that the magnetic declination at one place varies (see TERRESTRIAL MAGNETISM). He introduced the words cosine and cotangent (see TRIGONOMETRY), and he suggested to Henry Briggs, his friend and colleague, the use of the arithmetical complement (see Briggs' *Arithmetica Logarithmica*, cap. xv., and LOGARITHMS).

His practical inventions are *Gunter's Chain*, the chain in common use for surveying, 22 yd. long and divided into 100 links;

Gunter's Line, a logarithmic line, the forerunner of the slide rule;

Gunter's Quadrant, used to find the hour of the day, the sun's azimuth, etc., and also to take the altitude of an object in degrees; and

Gunter's Scale (generally called by seamen the *Gunter*), a large plane scale, engraved with various lines of numbers and used to solve problems in navigation, trigonometry, etc., with the aid of a pair of compasses.

GÜNTHER, JOHANN CHRISTIAN (1695–1723), German poet, was born at Striegau, Lower Silesia, on April 8, 1695. He studied medicine at Wittenberg; but he was idle and dissipated and came to a complete rupture with his family. In 1717 he went to Leipzig, where he was befriended by J. B. Mencke (1674–1732), who recognized his genius. A recommendation from Mencke to Frederick Augustus II. of Saxony, king of Poland, proved worse than useless, as Günther appeared at the audience drunk. He died at Jena on March 15, 1723, when only in his 28th year. Goethe pronounces Günther to have been a poet in the fullest sense of the term. His lyric poems reveal fine imagination, clever wit and a true ear for melody and rhythm; but dull or vulgar witticisms are not infrequently found side by side with the purest inspirations of his genius.

Günther's collected poems were published in four volumes (Breslau, 1723–1735). They are also included in vol. vi. of Tittmann's *Deutsche Dichter des 17ten Jahrh.* (Leipzig, 1874), and vol. xxxviii. of Kürschner's *Deutsche Nationalliteratur* (1883). A life of him by Siebrand appeared at Leipzig in 1738. See Hoffmann von Fallersleben, *J. Ch. Günther* (Breslau, 1833); M. Kalbeck, *Neue Beiträge zur Biographie des Dichters C. Günther* (Breslau, 1879); A. Hoffmann, *Deutsche Dichter im Schlesienschen Gebirge* (1897) and *Die Wahrheit über Günthers Leonore* (1925).

GÜNTHER OF SCHWARZBURG (1304–1349), German king, was a descendant of the counts of Schwarzburg and the younger son of Henry VII., count of Blankenburg. He was elected

German king at Frankfort on Jan. 30, 1349 by four of the electors, who were partisans of the house of Wittelsbach and opponents of Charles of Luxemburg, afterwards the emperor Charles IV. Charles defeated him at Eltville, and Günther renounced his claims for the sum of 20,000 marks of silver. He died three weeks afterwards at Frankfort, and was buried in the cathedral.

See Graf L. Utterodt zu Scharffenberg, *Günther, Graf von Schwarzburg, erzählter deutscher König* (Leipzig, 1862); and K. Janson, *Das Königtum Günthers von Schwarzburg* (Leipzig, 1880).

GUNTRAM or **GONTRAN** (561–592), king of Burgundy, was one of the sons of Clotaire I. On the death of his father (561) he and his three brothers divided the Frankish realm between them. Guntram receiving as his share the valleys of the Saône and Rhone, together with Berry and the town of Orleans, which he made his capital. On the death of Charibert (567), he further obtained the *civitates* of Saintes, Angoulême and Périgueux. During the civil war which broke out between the kings of Neustria and Austrasia, he sought to maintain equilibrium. After the assassination of Sigebert (575), he took the youthful Childebert II. under his protection. After the death of Chilperic (584) he protected the young Clotaire II., and prevented Childebert from seizing his dominions. The danger to the Frankish realm caused by the expedition of Gundobald (585), and the anxiety which was caused him by the revolts of the great lords in Austrasia finally decided him in favour of Childebert. He adopted him as his son, and recognized him as his heir at the treaty of Andelot (587); he also helped him to crush the great lords, especially Ursion and Berthefried, who were conquered in la Woëvre. From this time on he ceased to play a prominent part in the affairs of Austrasia. He died in 592, and Childebert received his inheritance without opposition.

See Krusch, "Zur Chronologie der merowingischen Könige," in the *Forschungen zur deutschen Geschichte*, xxii. 451–490; Ulysse Chevalier, *Bio-bibliographie* (2nd ed.), s.v. "Guntram."

GUNTUR, a town and district of British India, in the Madras presidency. The town (pop. in 1921, 48,184) has a station on the Bellary-Bezwada branch of the Madras and Southern Mahratta railway. It is situated east of the Kondavid hills, and is very healthy. It appears to have been founded in the 18th century by the French. At the time of the cession of the Circars to the English in 1765, Guntur was exempted during the life of Basalat Jang, whose personal *jagir* it was. In 1788 it came into British possession, the cession being confirmed in 1823. It has an important trade in tobacco and cotton, with presses and ginning factories, tobacco factories and oil and rice mills. There is a college and training schools. The DISTRICT OF GUNTUR, constituted in 1904 from territory which till then had been divided between Kistna and Nellore, has an area of 5,735 sq.m.; population (1921) 1,809,574. The district is bounded on the east and north by the river Kistna; in the west a part of the boundary is formed by the Gundlakamma river. Most of the district is a fertile plain irrigated by canals from the Kistna, and producing cotton, rice and other crops. The population is increasing, owing to the increased area of irrigated land. Saltpetre is worked.

GUPTA, SIR KRISHNA GOVINDA (1851–1926), Indian statesman, was a native of eastern Bengal, and was educated at Calcutta university. He then came to England, passed for the Indian Civil Service, and was called to the bar. He had a distinguished career in the civil service, and in 1907 was appointed one of the two Indian members on the India Council. He retired in 1915, and devoted his leisure partly to promoting the education of Indian women. Gupta received the K.C.S.I. in 1911. He died on March 30, 1926.

GURA, EUGEN (1842–1906), German singer, was born near Saatz in Bohemia on Nov. 8, 1842, and studied singing at the Munich Conservatorium. In 1865 he made his début at the Munich opera, and in the following years he gained the highest reputation in Germany, being engaged principally at Leipzig till 1876 and then at Hamburg till 1883. He was one of the greatest Wagnerian singers of his time and his Hans Sachs is still remembered. He died at Aufkirchen, Bavaria, on Aug. 26, 1906.

GURDASPUR, a town and district of British India, in the Lahore division of the Punjab. The town had a population in 1921 of 8,906. It has a fort (now containing a Brahman monastery) which was famous for the siege it sustained in 1712 from the Moguls.

The DISTRICT comprises an area of 1,889 sq.m. It occupies the submontane portion of the Bari Doab, or tract between the Beas and the Ravi. An intrusive spur of the British dominions runs northward into the lower Himalayan ranges, to include the mountain sanatorium of Dalhousie, 7,687 ft. above sea-level. This station, which has a large fluctuating population during the warmer months, crowns the most westerly shoulder of a magnificent snowy range, the Dhaoladhar, between which and the plain two minor ranges intervene. The district contains several large *jhils* or swampy lakes, and is famous for its snipe-shooting. It is historically important in connection with the rise of the Sikh confederacy. The whole of the Punjab was then distributed among the Sikh chiefs who triumphed over the imperial governors. In the course of a few years, however, the maharaja Ranjit Singh acquired all the territory which those chiefs had held. Pathankot and the neighbouring villages in the plain, together with the whole hill portion of the district, formed part of the area ceded by the Sikhs to the British after the first Sikh war in 1846. In 1921 the population was 852,192. A branch of the North-Western railway runs through the district. The largest town and chief commercial centre is Batala. There are important woollen mills at Dhariwal, and besides their products the district exports cotton, sugar, grain and oil-seeds.

GURGAON, a town and district of British India, in the Umballa division of the Punjab. The town (pop. in 1921, 5,107) is the headquarters of the district, but is otherwise unimportant. The district has an area of 2,263 sq.m. It comprises the southernmost corner of the Punjab province, stretching away from the level plain towards the hills of Rajputana. Two low rocky ranges enter its borders from the south and run northward in a bare and unshaded mass toward the plain country. To the west lies the subdivision of Rewari, consisting of a sandy plain dotted with isolated hills. Numerous torrents carry off the drainage from the upland ranges, and the most important among them empty themselves at last into the Najafgarh *jhil*. Salt is manufactured in wells at several villages. The mineral products are iron ore, copper ore, plumbago and ochre.

In 1803 Gurgaon district passed into the hands of the British after Lord Lake's conquests. On the outbreak of the Mutiny in May 1857, the Nawab of Farukhnagar, the principal feudatory of the district, rose in rebellion. The Meos and many Rajput families followed his example. After the fall of the rebel capital, a force marched into the district and either captured or dispersed the leaders of rebellion. The territory of the Nawab was confiscated. Civil administration was resumed under orders from the Punjab government, to which province the district was formally annexed on the final pacification of the country. The population in 1921 was 682,003. The largest town and chief trade centre is Rewari. The district is now traversed by several lines of railway, and some irrigation is provided by the Agra canal. The chief trade is in cereals, but hardware is also exported.

GURKHA, the ruling Hindu caste in Nepal (*q.v.*). Courageous, faithful and self-reliant, they make excellent riflemen, at their best in hill-warfare. The national weapon is the *kukri*, a heavy curved knife, used for every conceivable purpose.

GURKO, OSSIP VLADIMIROVICH (1828–1901), Russian field-marshal, was born on Nov. 15, 1828. He fought in the Russo-Turkish War (1877–78), and in June 1877 with the rank of lieutenant-general, commanded a detachment which was to advance to Trnovo, with the object of forcing one of the passes and raising a revolt in Bulgaria. He took part in the attack on the Shipka pass, which he was to attack from the south, while the VIII. Corps attacked simultaneously from the north. The Turks delayed Gurko's advance, with the result that he failed to co-operate and the VIII. Corps was repulsed (July 17, 1877). After the war Gurko was made successively governor-general of St. Petersburg (1879), Odessa (1882) and Warsaw (1883). He

retired in 1894, having attained the rank of field-marshal, and died on June 28, 1901, at Sacharov (Tver).

GURKO, VASILII (1864–), Russian general, was born in 1864. He was educated in the Corps of Pages, and in 1885 was given a commission in the Grodno Hussar regiment. In 1911 he was chief of the 1st Cavalry division, with which in Aug. 1914 he advanced into Eastern Prussia. In 1915 he was the commander of the VI. corps. At the end of 1917, during General Alexeiev's illness, he fulfilled the duties of chief of staff. Later, after the revolution, he was dismissed by Kerensky, because of his objections to risking an offensive with the army in its then condition of ferment, and of his outspoken opinions as to the causes of this condition. Gurko was imprisoned, released, imprisoned again, and finally sent out of Russia by way of Archangel, with his wife, who was killed in action at a French Red Cross dressing-station on March 23, 1918. General Gurko published *Memories and Impressions of War and Revolution in Russia* (Eng. ed. 1918).

GURNARD (*Trigla*), a genus of fishes forming a group of the family *Triglidae*, recognized by the three first fin-rays of the pectoral fin being detached to form movable finger-like appendages, serving as organs of touch and of locomotion along the bottom, and by their large, angular, bony head. Gurnards are coast-fishes, generally distributed over the tropical and temperate areas; of the 40 species known, six occur on the coast of Great Britain. Although never found far from the coast, gurnards descend to several hundred fathoms; they are caught chiefly by the trawl. In young fishes, the pectorals are comparatively longer than in the adult, extending to the end of the body. These fins are beautifully coloured, especially in the young; they help to prevent the fish from sinking. When taken out of the water, gurnards emit a grunting noise produced by the vibrations of a perforated diaphragm across the cavity of the air-bladder. Their flesh is white, firm, and wholesome.

GURNEY, the name of an English family of bankers and merchants, descendants of Hugh de Gournay, who accompanied William the Conqueror to England. At Norwich in 1770 the brothers John and Henry Gurney founded a banking-house, the business passing in direct line to SAMUEL GURNEY (1786–1856) who assumed the control of the Norwich bank in 1809. Samuel Gurney also took over about the same time the control of the London bill-broking business of Richardson, Overend and Company, founded in 1800. At that time bill-discounting was carried on in a spasmodic fashion by the ordinary merchant in addition to his regular business, but Richardson considered that there was room for a London house which should devote itself entirely to the trade in bills. This idea proved an instant success. The title of the firm was changed to Overend, Gurney and Company, and for 40 years it was the greatest discounting-house in the world. The house became known as "the bankers' banker," and secured many of the Bank of England's clients. Samuel Gurney died in 1856. During the latter years of his life philanthropic undertakings monopolized his attention. In 1865 the business of Overend, Gurney and Company was converted into a joint stock company, and in 1866 the firm suspended payment with liabilities amounting to eleven millions sterling.

GURNEY, EDMUND (1847–1888), English psychologist, was born at Hersham, near Walton-on-Thames, on March 23, 1847. He was educated at Blackheath and at Trinity College, Cambridge, and found his life-interest in that outlying field of psychology which is called "Psychical Research. In 1882 the Society for Psychical Research was founded, the first results being embodied in *Phantasms of the Living*, 2 vols. (1886), in the *Proceedings* of the Society, and in Gurney's remarkable essay, *Hallucinations*. The chief consequence was to furnish evidence for the process called "telepathy." In addition to his psychological writings, Gurney was the author of *The Power of Sound* (1880), and *Tertium Quid* (1887), a collection of essays. He died at Brighton on June 23, 1888, from the effects of an overdose of narcotic medicine. See PSYCHICAL RESEARCH.

GURWOOD, JOHN (1790–1845), British soldier, entered the army in 1808. He served through the Peninsular War, distinguishing himself at Ciudad Rodrigo (1812), and as brigade-major

of Lambert's brigade of the 6th Infantry Division in all the important actions of 1813–14. He then served under the prince of Orange in the Netherlands, and was severely wounded (for the third time) at Waterloo. Gurwood was for many years Wellington's private secretary; he was occupied from 1837 to his death (Dec. 25, 1845) with the preparation of *Wellington's Despatches*.

GUSLA or **GUSLI**, an ancient stringed instrument still in use among the Slavonic races. The modern Serbian gusla is a kind of tanbur (see PANDURA), consisting of a round, concave body covered with a parchment sound-board and but one horse-hair string. The gusla is played with a primitive bow called *goudalo*. Among the Russians, the gusli is an instrument of a different type, a kind of psaltery having five or more strings stretched across a flat, shallow sound-chest in the shape of a wing.

BY COURTESY OF METROPOLITAN MUSEUM OF ART, N.Y.

THE BULGARIAN GUSLA, STILL IN USE AMONG SLAVONIC RACES

for 12 months in the island fortress of Kalö, on the east coast of Jutland, but contrived to escape to Lübeck in September 1519. There he found an asylum till May 20, 1520, when he chartered a ship to Kalmar, one of the few Swedish fortresses which held out against Christian II.

It was while hunting near Lake Mälär that the news of the Stockholm massacre was brought to him by a peasant, who told him that a price had been set upon his head. In his extremity Gustavus appealed to the sturdy yeomen of the dales, and finally drove the Danes out of Sweden (1521–23). But his worst troubles only began after his coronation on June 6, 1523. By releasing his country from the tyranny of Denmark, Gustavus had made the free independent development of Sweden a possibility. It was for him to realize that possibility. First of all, order had to be evolved from the chaos in which Sweden had been plunged by the disruption of the Union; and the shortest, perhaps the only, way thereto was to restore the royal authority, which had been in abeyance during 90 years. But an effective reforming monarchy must stand upon a sound financial basis; and the usual revenues of the crown were so diminished that they did not cover half the daily expenses of government. New taxes could only be imposed with extreme caution, while the country was still bleeding from the wounds of a long war. Moreover, the lack of capable, trustworthy administrators threw the whole burden of government exclusively on the shoulders of the new king, a young man of 27. Half his time was taken up in travelling from one end of the kingdom to the other and doing purely clerical work for want of competent assistance; in 1533, he could not send an ambassador to Lübeck because not a single man in his council, except himself, knew German. This lack of native talent compelled Gustavus to employ the services of foreign adventurers like Berent von Mehlen, John von Hoja, Konrad von Pyhy and others.

Gustavus had constantly to be on the watch lest the Swedish peasantry should encroach on his prerogative. He succeeded in putting down the four rebellions between 1525 and 1542, but the strain upon his resources was very damaging, and more than once he was on the point of abdicating and emigrating out of sheer weariness. He was, moreover, in constant fear of the Danes. Necessity compelled him (1534–36) to take part in *Grevens fejde* (Counts' War) (see DENMARK, History), as the ally of Christian III., but his exaggerated distrust of the Danes was invincible. A fresh cause of dispute was generated in 1548, when Christian III.'s daughter was wedded to Duke Augustus of Saxony. On that occa-

sion, apparently by way of protest against the decree of the diet of Vesterås (Jan. 15, 1544), declaring the Swedish crown hereditary in Gustavus's family, the Danish king caused to be quartered on his daughter's shield not only the three Danish lions and the Norwegian lion with the axe of St. Olaf, but also "the three crowns" of Sweden. Gustavus, naturally suspicious, was perturbed by the innovation, and warned all his border officials to be watchful. In 1557 he even wrote a letter of protest to the Danish king, but Christian III. replied that "the three crowns" signified not Sweden in especial, but the three Scandinavian kingdoms, and that their insertion in the Danish shield was only reminiscent of the union of Kalmar. But Gustavus was not satisfied, and this was the beginning of "the three crowns" dispute which did so much damage to both kingdoms.

The rupture of Gustavus with the Holy See was a purely political act, as Gustavus, personally, had no strong dogmatic convictions. He not unnaturally expressed his amazement when Olavus Petri informed him that the pope was antichrist. He consulted the older and graver Laurentius Andreae, who told him how "Doctor Martinus had clipped the wings of the pope, the cardinals and the big bishops," which could not fail to be pleasing intelligence to a monarch who was never an admirer of episcopacy, while the rich revenues of the church were tempting to the impetuous ruler of an impoverished people. When the Protestant hierarchy was forcibly established in Sweden, matters were much complicated by the absolutist tendencies of Gustavus. The incessant labour, the constant anxiety, which were the daily portion of Gustavus Vasa during the 37 years of his reign, told at last even upon his magnificent constitution. In the spring of 1560, conscious of a decline of his powers, Gustavus summoned his last diet, to give an account of his stewardship. On June 16, 1560 the assembly met at Stockholm. Ten days later, supported by his sons, Gustavus greeted the estates in the great hall of the palace, when he took a retrospect of his reign. Four days later the diet passed a resolution confirming the hereditary right of Gustavus's son, Prince Eric, to the throne. The old king's last anxieties were now over and he could die in peace. He expired on Sept. 29, 1560.

Gustavus was thrice married. His first wife, Catherine, daughter of Magnus I., duke of Saxe-Lauenburg, bore him in 1533 his eldest son Eric. This union was neither long nor happy, but the blame for its infelicity is generally attributed to the lady, whose abnormal character was reflected and accentuated in her son. Much more fortunate was Gustavus's second marriage with his own countrywoman, Margaret Lejonhufvud, who bore him five sons and five daughters, of whom three sons, John, Magnus and Charles, and one daughter, Cecilia, survived their childhood. Queen Margaret died in 1551; and a twelvemonth later Gustavus wedded her niece, Catharine Stenbock, a handsome girl of 16, who survived him more than 60 years.

Gustavus's outward appearance in the prime of life is thus described by a contemporary: "He was of the middle height, with a round head, light yellow hair, a fine long beard, sharp eyes, a ruddy countenance . . . and a body as fitly and well proportioned as any painter could have painted it." Learned he was not, but he had naturally bright and clear understanding, an unusually good memory, and a marvellous capacity for taking pains. He was also very devout, and his morals were irreproachable. On the other hand, Gustavus had his full share of the family failings of irritability and suspiciousness, the latter quality becoming almost morbid under the pressure of adverse circumstances. His energy too not infrequently degenerated into violence, and when crossed he was apt to be tyrannical.

GUSTAVUS II. ADOLPHUS (1594-1632), king of Sweden, the eldest son of Charles IX. and of Christina, daughter of

Adolphus, duke of Holstein-Gottorp, was born at Stockholm castle on Dec. 9, 1594. From the first he was carefully nurtured to be the future prop of Protestantism by his austere parents. Gustavus was well grounded in the classics, and his linguistic accomplishments were extraordinary. He may be said to have grown up with two mother-tongues, Swedish and German; at twelve he had mastered Latin, Italian and Dutch; and he learnt subsequently to express himself in Spanish, Russian and Polish. But his practical father took care that he should grow up a prince, not a pedant. So early as his ninth year he was introduced to public life; at 13 he received petitions and conversed officially with the foreign ministers; at 15 he administered his duchy of Vestmanland and opened the Örebro diet with a speech from the throne; indeed from 1610 he may be regarded as his father's co-regent. In all martial and chivalrous accomplishments he was already an adept; and when, a year later, he succeeded to supreme power, his superior ability was as uncontested as it was incontestable.

The first act of the young king was to terminate the fratricidal struggle with Denmark by the peace of Knäred (Jan. 28, 1613). Simultaneously, another war, also an heritage from Charles IX., had been proceeding in the far distant regions round lakes Ilmen, Peipus and Ladoga, with Great Novgorod as its centre. It was not, however, like the Danish War, a national danger, but a political speculation meant to be remunerative and compensatory, and was concluded very advantageously for Sweden by the peace of Stolbova on Feb. 27, 1617 (see SWEDEN: *History*). By this peace Gustavus succeeded in excluding Muscovy from the Baltic. "I hope to God," he declared to the Stockholm diet in 1617, when he announced the conclusion of peace, "that the Russians will feel it a bit difficult to skip over *that* little brook." The war with Poland which Gustavus resumed in 1621 was a much more difficult affair. It began with an attack upon Riga as the first step towards conquering Livonia. Riga was invested on Aug. 13 and surrendered on Sept. 15; on Oct. 3 Mitau was occupied; but so great were the ravages of sickness during the campaign that the Swedish army had to be reinforced by no fewer than 10,000 men. A truce was thereupon concluded and hostilities were suspended till the summer of 1625, in the course of which Gustavus took Kokenhusen and invaded Lithuania. In Jan. 1626 he attacked the Poles at Waihof and scattered the whole of their army after slaying a fifth part of it. This victory, remarkable besides as Gustavus's first pitched battle, completed the conquest of Livonia. As, however, it became every year more difficult to support an army in the Dvina district, Gustavus now resolved to transfer the war to the Prussian provinces of Poland with a view to securing the control of the Vistula, as he had already secured the control of the Dvina. At the end of 1626, the Swedish fleet, with 14,000 men on board, anchored in front of the chain of sand-dunes which separates the Frische-Haff from the Baltic. Pillau, the only Baltic port then accessible to ships of war, was at once occupied, and Königsberg shortly afterwards was scared into an unconditional neutrality. July was passed in conquering the bishopric of Ermeland. The surrender of Elbing and Marienburg placed Gustavus in possession of the fertile and easily defensible delta of the Vistula, which he treated as a permanent conquest, making Axel Oxenstjerna its first governor-general. Communications between Danzig and the sea were cut off by the erection of the first of Gustavus's famous entrenched camps at Dirschau. From the end of August 1626 the city was blockaded, and in the meantime Polish irregulars, under the capable Stanislaus Koniecpolski, began to harass the Swedes. But the object of the campaign, a convenient basis of operations, was won; and in October the king departed to Sweden to get reinforcements. He returned in May 1627 with 7,000 men, which raised his forces to 14,000, against which Koniecpolski could only oppose 9,000. But his superior strategy frustrated all the efforts of the Swedish king, who in the course of the year was twice dangerously wounded and so disabled that he could never wear armour again. Gustavus had made extensive preparations for the ensuing campaign and took the field with 32,000 men. But once again, though far outnumbered, and unsupported by his own government, the Polish grand-hetman proved more than a match for Gustavus, who, on Sept. 10, broke up his camp and returned to

Prussia; the whole autumn campaign had proved a failure and cost him 5,000 men. During the ensuing campaign of 1629 Gustavus had to contend against the combined forces of Koniecpolski and 10,000 of Wallenstein's mercenaries. The Polish commander now showed the Swedes what he could do with adequate forces. At Stuhm, on June 29, he defeated Gustavus, who lost most of his artillery and narrowly escaped capture. The result of the campaign was the conclusion of the six years' truce of Altmark, which was very advantageous to Sweden.

And now Gustavus turned his attention to Germany. The motives which induced the Swedish king to intervene directly in the Thirty Years' War are told us by himself in his correspondence with Oxenstjerna. Here he says plainly that it was the fear lest the emperor should acquire the Baltic ports and proceed to build up a sea-power dangerous to Scandinavia. For the same reason, the king rejected the chancellor's alternative of waging a simply defensive war against the emperor by means of the fleet, with Stralsund as his base. He was convinced by the experience of Christian IV. of Denmark that the enemies' harbours could be wrested from them only by a successful offensive war on land; and, while quite alive to the risks of such an enterprise in the face of two large armies, Tilly's and Wallenstein's, each of them larger than his own, he argued that the vast extent of territory and the numerous garrisons which the enemy was obliged to maintain, more than neutralized his numerical superiority. Merely to blockade all the German ports with the Swedish fleet was equally impossible. The Swedish fleet was too weak for that; it would be safer to take and fortify the pick of them. In Germany itself, if he once got the upper hand, he would not find himself without resources. It is no enthusiastic crusader, but an anxious and far-seeing if somewhat speculative statesman who thus opens his mind to us. No doubt religious considerations largely influenced Gustavus. He had the deepest sympathy for his fellow-Protestants in Germany; he regarded them as God's peculiar people, himself as their divinely appointed deliverer. But his first duty was to Sweden; and, naturally and rightly, he viewed the whole business from a predominantly Swedish point of view. Lutherans and Calvinists were to be delivered from a "soul-crushing tyranny"; but they were to be delivered by a foreign if friendly power; and that power claimed as her reward the hegemony of Protestant Europe and all the political privileges belonging to that exalted position.

On May 19, 1630 Gustavus solemnly took leave of the estates of the realm assembled at Stockholm. He appeared before them holding in his arms his only child and heiress, the little princess Christina, then in her fourth year, and tenderly committed her to the care of his loyal and devoted people. Then he solemnly took the estates to witness, as he stood there "in the sight of the Almighty," that he had begun hostilities "out of no lust for war, as many will certainly devise and imagine," but in self-defence and to deliver his fellow-Christians from oppression. On June 7, 1630 the Swedish fleet set sail, and two days after midsummer day, the whole army, 16,000 strong, was disembarked at Peenemünde. Gustavus's plan was to take possession of the mouths of the Oder Haff, and, resting upon Stralsund in the west and Prussia in the east, penetrate into Germany. In those days rivers were what railways now are, the great military routes; and Gustavus's German war was a war waged along river lines. The opening campaign was to be fought along the line of the Oder. Stettin, the capital of Pomerania, and the key of the Oder line, was occupied and converted into a first-class fortress. He then proceeded to clear Pomerania of the piebald imperial host composed of every nationality under heaven, and officered by Italians, Irishmen, Czechs, Croats, Danes, Spaniards and Walloons. Gustavus's army has often been described by German historians as an army of foreign invaders; in reality it was far more truly Teutonic than the official defenders of Germany at that period. Gustavus's political difficulties (*see SWEDEN: History*) chained him to his camp for the remainder of the year. But the dismissal of Wallenstein and the declaration in Gustavus's favour of Magdeburg, the greatest city in the Lower Saxon Circle, and strategically the strongest fortress of north Germany, encouraged him to advance boldly. But first, honour as well as expediency moved him to attempt to relieve Magdeburg,

now closely invested by the imperialists, especially as his hands had now been considerably strengthened by a definite alliance with France (treaty of Bärwalde, Jan. 13, 1631). Magdeburg, therefore, became the focus of the whole campaign of 1631; but the obstructive timidity of the electors of Brandenburg and Saxony threw insuperable obstacles in his way, and, on the very day when John George I. of Saxony closed his gates against Gustavus the most populous and prosperous city in north Germany became a heap of smoking ruins (May 20). Gustavus, still too weak to meet the foe, entrenched himself at Werben, at the confluence of the Havel and Elbe. Only on Sept. 12 did the elector of Saxony, alarmed for the safety of his own states, now invaded by the emperor, place himself absolutely at the disposal of Gustavus; and, five days later, at the head of the combined Swedish-Saxon army, though the Swedes did all the fighting, Gustavus routed Tilly at the famous battle of Breitenfeld, north of Leipzig.

The question now was: In what way should Gustavus utilize his advantage? Should he invade the Austrian crown lands, and dictate peace to Ferdinand II. at the gates of Vienna? Or should he pursue Tilly westwards and crush the league at its own hearth and home? Oxenstjerna was the first alternative, but Gustavus decided in favour of the second. His decision has been greatly blamed. More than one modern historian has argued that if Gustavus had done in 1631 what Napoleon did in 1805 and 1809, there would have been a fifteen instead of a thirty years' war. But it should be borne in mind that, in the days of Gustavus, Vienna was by no means so essential to the existence of the Habsburg monarchy as it was in the days of Napoleon; and even Gustavus could not allow so dangerous an opponent as Tilly time to recover himself. Accordingly, he set out for the Rhine, taking Marienberg and Frankfurt on his way, and on Dec. 20 entered Mainz, where he remained throughout the winter of 1631-32. At the beginning of 1632, in order to bring about the general peace he so earnestly desired, he proposed to take the field with an overwhelming numerical majority. The signal for Gustavus to break up from the Rhine was the sudden advance of Tilly from behind the Danube. Gustavus pursued Tilly into Bavaria, forced the passage of the Danube at Donauwörth and the passage of the Lech, in the face of Tilly's strongly entrenched camp at Rain, and pursued the flying foe to the fortress of Ingolstadt where Tilly died of his wounds a fortnight later. Gustavus then liberated and garrisoned the long-oppressed Protestant cities of Augsburg and Ulm, and in May occupied Munich. The same week Wallenstein chased John George from Prague and manoeuvred the Saxons out of Bohemia. Then, armed as he was with plenipotentiary power, he offered the elector of Saxony peace on his own terms. Gustavus suddenly saw himself exposed to extreme peril. If Tilly had made John George such an offer as Wallenstein was now empowered to make, the elector would never have become Gustavus's ally; would he remain Gustavus's ally now? Hastily quitting his quarters in upper Swabia, Gustavus hastened towards Nuremberg on his way to Saxony, but finding that Wallenstein and Maximilian of Bavaria had united their forces, he abandoned the attempt to reach Saxony, and both armies confronted each other at Nuremberg which furnished Gustavus with a point of support of the first order. He quickly converted the town into an entrenched and fortified camp. Wallenstein followed the king's example, and entrenched himself on the western bank of the Regnitz in a camp twelve English miles in circumference. His object was to pin Gustavus fast to Nuremberg and cut off his retreat northwards. Throughout July and August the two armies faced each other immovably. On Aug. 24 after an unsuccessful attempt to storm Alte Veste, the key of Wallenstein's position, the Swedish host retired southwards.

Towards the end of October, Wallenstein, after devastating Saxony, was preparing to go into winter quarters at Lützen, when the king surprised him as he was crossing the Rippach (Nov. 1) and a rearguard action favourable to the Swedes ensued. Indeed, but for nightfall, Wallenstein's scattered forces might have been routed. During the night, however, Wallenstein re-collected his host for a decisive action, and at daybreak on Nov. 6, while an autumn mist still lay over the field, the battle began. It was obviously Gustavus's plan to drive Wallenstein away from the Leip-

zig road, north of which he had posted himself, and thus, in case of success, to isolate, and subsequently, with the aid of the Saxons in the Elbe fortresses, annihilate him. The king, on the Swedish right wing, succeeded in driving the enemy from the trenches and capturing his cannon. What happened after that is mere conjecture, for a thick mist now obscured the autumn sun, and the battle became a colossal mêlée the details of which are indistinguishable. It was in the midst of that awful obscurity that Gustavus met his death—how or where is not absolutely certain; but it would seem that he lost his way in the darkness while leading the Småland horse to the assistance of his infantry, and was despatched by a hostile horseman as he lay severely wounded on the ground.

By his wife, Marie Eleonora, a sister of the elector of Brandenburg, whom he married in 1620, Gustavus Adolphus had one daughter, Christina, who succeeded him on the throne of Sweden.

GUSTAVUS III. (1746-1792), king of Sweden, the eldest son of Adolphus Frederick, king of Sweden, and Louisa Ulrica of Prussia, sister of Frederick the Great, was born on Jan. 24, 1746. Gustavus was educated under the care of two eminent Swedish statesmen, Carl Gustaf Tessin and Carl Scheffer; but he owed most, perhaps, to the poet and historian Olof von Dalin. His teachers were amazed by the brilliance of his natural gifts, and, while still a boy, he possessed that charm of manner which was to make him so fascinating and so dangerous in later life, coupled with the strong dramatic instinct which won for him his honourable place in Swedish literature. There was scarce a French author of his day with whose works he was not intimately acquainted; while his enthusiasm for the new French ideas of enlightenment was as sincere as his mother's. On Nov. 4, 1766, Gustavus married Sophia Magdalena, daughter of Frederick V. of Denmark. The match was an unhappy one.

Gustavus first intervened in politics in 1768, at the time of his father's interregnum, when he compelled the dominant Cap faction to summon an extraordinary diet from which he hoped for the reform of the Constitution in a monarchical direction. But the Hats refused to redeem the pledges which they had given before the elections. "That we should have lost the constitutional battle does not distress us so much," wrote Gustavus, "but what does dismay me is to see my poor nation so sunk in corruption as to place its own felicity in absolute anarchy." From Feb. 4 to March 25, 1771, Gustavus was in Paris, where the poets and the philosophers paid him enthusiastic homage. But his visit to the French capital was a political mission. The duc de Choiseul, weary of Swedish anarchy, had resolved to discuss with him the best method of bringing about a revolution in Sweden. Before he departed, the French Government undertook to pay the outstanding subsidies to Sweden unconditionally, at the rate of one and a half million livres annually; and the comte de Vergennes was transferred from Constantinople to Stockholm. On his way home Gustavus visited his uncle, Frederick the Great, at Potsdam. Frederick bluntly informed his nephew that, in concert with Russia and Denmark, he had guaranteed the integrity of the existing Swedish constitution, and advised the young monarch to play the part of mediator and abstain from violence.

On his return to Sweden Gustavus made a sincere attempt to mediate between the Hats and Caps who were ruining the country between them (see SWEDEN: History). On June 21, 1771, he

opened his first parliament in a moving speech. Addressing the diet in the Swedish tongue, he laid stress on the necessity of sacrifice for the common weal and offered to mediate between contending factions. A composition committee was actually formed, but it proved illusory from the first. The subsequent attempts of the dominant Caps still further to limit the prerogative, induced Gustavus at last to consider the possibility of a revolution. Of its necessity there could be no doubt. Under the sway of the Cap faction, Sweden, already the vassal, could not fail to become the prey of Russia. Only by a swift *coup d'état* could the independence of a country isolated from the rest of Europe by a hostile league, be saved from absorption into that northern system, the invention of Count Nikita Panin. At this juncture Gustavus was approached by Jakob Magnus Sprengtporten, a Finnish nobleman of determined character, with the project of a revolution. He undertook to seize the fortress of Sveaborg, and, Finland once secured, to embark for Sweden, meet the king and his friends near Stockholm, and surprise the capital by a night attack, when the estates were to be forced to accept a new constitution from the king.

The plotters were reinforced by an ex-ranger from Scania (Skåne), Johan Kristoffer Toll, also a victim of Cap oppression. Toll proposed that a second revolt should break out in the province of Scania, to confuse the Government still more, and undertook to secure the southern fortress of Kristianstad. It was finally arranged that, a few days after the Finnish revolt had begun, Kristianstad should declare against the Government. Prince Charles was thereupon to mobilize the garrisons of all the southern fortresses, ostensibly to crush the revolt at Kristianstad; but on arriving before the fortress he was to make common cause with the rebels, and march upon the capital from the south, while Sprengtporten attacked it simultaneously from the east. On Aug. 6, 1772, Toll succeeded in winning the fortress of Kristianstad, and on the 16th Sprengtporten successfully surprised Sveaborg. But contrary winds prevented him from crossing to Stockholm, and in the meanwhile events had occurred which made his presence there unnecessary.

On Aug. 16, the Cap leader, Ture Rudbeck, arrived at Stockholm with the news of the insurrection in the south, and Gustavus, finding himself isolated in the midst of enemies, resolved to strike the decisive blow without waiting for the arrival of Sprengtporten. On the evening of the 18th all the officers whom he thought he could trust received instructions to assemble in the square facing the arsenal on the following morning. At ten o'clock on the 19th Gustavus rode to the arsenal, joined on the way by his adherents, so that by the time he reached his destination he had about 200 officers in his suite. After parade he reconducted them to the guard-room of the palace and unfolded his plans. He then dictated a new oath of allegiance, absolving them from their allegiance to the estates, and binding them to obey their lawful king, Gustavus III. Meanwhile the senate and the governor-general, Rudbeck, had been arrested and the fleet secured. On the evening of the 20th heralds proclaimed that the estates were to meet in the Rikssaal on the following day; every deputy absenting himself would be regarded as the enemy of his country and his king. On the 21st, a few moments after the estates had assembled, the king in full regalia appeared, and taking his seat on the throne, delivered that famous philippic in which he reproached the estates for their unpatriotic venality in the past. A new constitution was recited by the estates and accepted by them unanimously. The diet was then dissolved.

Gustavus was inspired by enthusiasm for the greatness and welfare of Sweden, and worked in the same reformatory direction as the other contemporary sovereigns of the "age of enlightenment." He took an active part in every department of business, but relied far more on extra-official counsellors of his own choosing than upon the senate. The effort to remedy the corruption which had been fostered by the Hats and Caps engaged a considerable share of his time and he even found it necessary to put the whole of a supreme court of justice (*Göta Hofrätt*) on its trial. Measures were taken to reform the administration and the judicial procedure, and torture as an instrument of legal

investigation was abolished. In 1774 an ordinance providing for the liberty of the press was issued, the national defences were developed on a "Great Power" scale, and the navy was so enlarged as to become one of the most formidable in Europe. The finances were set in good order by the "currency realization ordinance" of 1777, and in 1775 free trade in corn was promoted and a number of oppressive export-tolls abolished.

The poor law was amended, absolute religious liberty was proclaimed, and he even succeeded in inventing and popularizing a national costume which was in general use from 1778 till his death. His one economic blunder was the attempt to make the sale of spirits a government monopoly, which was an obvious infringement upon the privileges of the estates. His foreign policy, on the other hand, was at first both wise and wary. Thus, when the king summoned the estates to assemble at Stockholm on Sept. 3, 1778, he could give a brilliant account of his six years' stewardship. Never was a parliament more obsequious or a king more gracious. Yet, short as the session was, it was long enough to open the eyes of the deputies to the fact that their political supremacy had departed. They had changed places with the king, who for all his gentleness, guarded his prerogative jealously. Even the few who were patriotic enough to acquiesce in the change by no means liked it. The diet of 1778 had been obsequious; the diet of 1786 was mutinous. The consequence was that nearly all the royal propositions were either rejected outright or so modified that Gustavus himself withdrew them.

The diet of 1786 marks a turning-point in Gustavus's history. Henceforth we observe a determination on his part to rule without a parliament; a passage, cautious and gradual, yet unflinching, from semi-constitutionalism to semi-absolutism. His opportunity came in 1788, when the political complications arising out of his war with Catherine II. of Russia enabled him by the Act of Unity and Security (on Feb. 17, 1789) to override the opposition of the rebellious gentry, and, with the approbation of the three lower estates, establish a new constitution, in which, though the estates still held the power of the purse, the royal authority largely predominated. Throughout 1789 and 1790 Gustavus gallantly conducted the unequal struggle with Russia, finally winning in the Svenskund (July 9-10) the most glorious naval victory ever gained by the Swedish arms, the Russians losing one-third of their fleet and 7,000 men. A month later, on Aug. 14, 1790, peace was signed between Russia and Sweden at Värälä. The peace of Värälä saved Sweden from humiliating concessions, and in Oct. 1791 Gustavus took the bold step of concluding an eight years' defensive alliance with the empress, who thereby bound herself to pay her new ally annual subsidies amounting to 300,000 roubles.

Gustavus now aimed at forming a league of princes against the Jacobins, and every other consideration was subordinated thereto. His profound knowledge of popular assemblies enabled him accurately to gauge from the first the scope and bearing of the French Revolution. But he was hampered by poverty and the jealousy of the other European Powers, and, after showing once more his unrivalled mastery over masses of men at the brief Gefle diet (Jan. 22-Feb. 24, 1792), he fell a victim to a widespread aristocratic conspiracy. Shot in the back by Ankarström at a midnight masquerade at the Stockholm opera-house, on March 16, 1792, he died on the 29th.

Although he may be charged with many foibles and extravagances, Gustavus III. was indisputably one of the greatest sovereigns of the 18th century. Unfortunately his genius never had full scope, and his opportunity came too late. Gustavus was, moreover, a most distinguished author. He may be said to have created the Swedish theatre, and some of the best acting dramas in the literature are by his hand. His historical essays, notably the famous anonymous eulogy on Torstenson crowned by the Academy, are full of feeling and exquisite in style,—his letters to his friends are delightful. Every branch of literature and art interested him, every poet and artist of his day found in him a most liberal and sympathetic protector.

GUSTAVUS IV. (1778-1837), king of Sweden, the son of Gustavus III. and Queen Sophia Magdalena, was born at Stockholm, on Nov. 1, 1778. Carefully educated under the direction of Nils von Rosenstein, he grew up serious and conscientious. In 1797 he married Frederica Dorothea, daughter of Charles Frederick, grand-duke of Baden, a marriage which might have led to a war with Russia but for the hatred of the French republic shared by the emperor Paul and Gustavus IV., which served as a bond of union between them. Indeed the king's morbid horror of Jacobinism drove him to adopt all sorts of reactionary measures and to postpone his coronation for some years, so as to avoid calling together a diet; but the disorder of the finances, caused partly by the continental war and partly by the almost total failure of the crops in 1798 and 1799, compelled him to summon the estates to Norrköping in March 1800, and on April 3, Gustavus was crowned.

The change which now took place in Sweden's foreign policy and its consequences are elsewhere set forth (see SWEDEN: History). By the end of 1808 it was obvious that the king was insane. His violence had alienated his most faithful supporters, while his obstinate incompetence paralysed the national efforts. To remove a madman by force was the one remaining expedient; and this was successfully accomplished by a conspiracy of officers of the western army, headed by Adlersparre, the Anckarsvärds, and Adlercreutz. On March 13, 1809 seven of the conspirators broke into the royal apartments unannounced, seized the king, and conducted him to the château of Gripsholm; Duke Charles was persuaded to accept the leadership of a provisional Government, which was proclaimed the same day; and a diet, hastily summoned, approved the revolution.

On March 29, Gustavus, in order to save the crown for his son, voluntarily abdicated; but on May 10, the estates, dominated by the army, declared that his whole family had forfeited the throne. One June 5, the duke regent was proclaimed king under the title of Charles XIII., after accepting the new liberal constitution, which was ratified by the diet the same day. In December Gustavus and his family were transported to Germany. Gustavus now assumed the title of count of Gottorp, but subsequently called himself Colonel Gustafsson, under which pseudonym he wrote most of his works. Separated from his family, he led an erratic life for some years; was divorced from his consort in 1812; and finally settled at St. Gall in Switzerland in great loneliness and indigence. He died on Feb. 7, 1837, and, at the suggestion of King Oscar II. his body was brought to Sweden and interred in the Riddarholmskyrka.

GUSTAVUS V. (1858-), king of Sweden, son of Oscar II., king of Sweden and Norway, and Queen Sophia Wilhelmina, was born at Drottningholm on June 16, 1858. He entered the army, and was, like his father, a great traveller. As crown prince he held the title of duke of Wärmaland. He married in 1881 Victoria (b. 1862), daughter of Frederick William Louis, grand duke of Baden, and of Louise, princess of Prussia. The duchess of Baden was the granddaughter of Sophia, princess of Sweden, and the marriage of the crown prince thus effected a union between the Bernadotte dynasty and the ancient Swedish royal

house of Vasa. During the absence or illness of his father Gustavus repeatedly acted as regent, and was therefore already thoroughly versed in public affairs when he succeeded to the Swedish throne on Dec. 8, 1907, the crown of Norway having been separated from that of Sweden in 1905.

The crown prince, Oscar Frederick William Gustavus Adolphus, duke of Scania (b. 1882), married in 1905 Princess Margaret of Connaught (b. 1882, d. 1920), niece of King Edward VII. A son was born to them at Stockholm on April 22, 1906, and another son in the following year. The king's two younger sons were William, duke of Sudermania (b. 1884), and Eric, duke of Westmanland (b. 1889).

See G. Åsbrinkt, *Konung Gustav V. sextio år* (1918).

GUSTAVUS ADOLPHUS UNION, a society formed of members of the Evangelical Protestant churches of Germany, which has for its object the aid of feeble sister churches, especially in Roman Catholic countries. The project of forming such a society was first broached in connection with the bicentennial celebration of the battle of Lützen on the 6th of November 1832; a proposal to collect funds for a monument to Gustavus Adolphus having been adopted, it was agreed that the best memorial to the great champion of Protestantism would be the formation of a union for propagating his ideas. The society received a new impulse in 1841 through the energy and eloquence of Karl Zimmermann (1803-1877), under whose direction it became more definitely "evangelical" in its tone. The society has distributed about two and a half million pounds for church aid and development among various Protestant evangelical communities.

See K. Zimmermann, *Geschichte des Gustav-Adolf-Vereins* (Darmstadt, 1877).

GÜSTROW, a town of Germany, in the republic of Mecklenburg-Schwerin, on the Nebel and the railway from Lübeck to Stettin, 20 m. S. of Rostock. Pop. (1925) 18,837.

Güstrow, capital of the Wend district, was a place of some importance as early as the 12th century, and in 1219 it received Schwerin privileges. From 1316 to 1436 the town was the residence of the princes of the Wends, and from 1556 to 1695 of the dukes of Mecklenburg-Güstrow.

The principal buildings are the castle, erected in the middle of the 16th century, the cathedral, dating from the 13th century, restored in 1868, and the town hall (Rathaus), which dates from the 16th century. The town has machine works, foundries, saw-mills, breweries, distilleries, and manufactories of chemicals, sugar and soap. There is also a considerable trade in wool, corn, wood, butter and cattle.

GUTENBERG, JOHANN (c. 1398-1468), German printer, is supposed to have been born c. 1398-1399 at Mainz of well-to-do parents, his father being Friele zum Gensfleisch and his mother Elsgen Wyrich (or, from her birthplace, zu Gutenberg, the name he adopted). The family appears to have been expelled from Mainz and to have settled in Strasbourg. Gutenberg is said to have been living there in 1434, and to have seized and imprisoned the town clerk of Mainz for a debt due to him by the corporation of that city, releasing him, however, at the representations of the mayor and councillors of Strasbourg, and relinquishing at the same time all claims to the money.

In 1438 a partnership arrangement was made between Gutenberg, Andreas Dritzehn, and Andreas and Anton Heilmann, and that this had in view the art of printing has been inferred from the word "drucken" used by one of the witnesses in the law proceedings which soon after followed. An action was brought, after the death of Dritzehn, by his two brothers to force Gutenberg to accept them as partners in their brother's place, but the decision was in favour of the latter. Documents of 1441 and 1442 show him to have been still in Strasbourg, but there is no trace of him between March 1444 and Oct. 1448. About 1450 Johann Fust (q.v.) advanced him 800 guilders to promote his work, on no security except that of "tools" still to be made. Fust seems also to have undertaken to advance him 300 guilders a year for expenses, but he does not appear to have ever done so. If at any time they disagreed, Gutenberg was to return the 800 guilders, and the "tools" were to cease to be security. In the minutes of

the law-suit of 1455 Gutenberg says that he had to make his "tools" with the money advanced. But he is presumed to have begun a large folio Latin Bible, and to have printed during its progress some smaller books¹ and likewise the Letter of Indulgence (of April 12, 1451, by Pope Nicholas V. in aid of John II., king of Cyprus, against the Turks), of 31 lines, having the earliest printed date 1454, of which several copies are preserved in various European libraries.

It is not known whether any books were printed while this partnership between Gutenberg and Fust lasted. Trithemius (*Ann. Hirsaug.* ii. 421) says they first printed, from wooden blocks, a vocabulary called *Catholicon*, which cannot have been the *Catholicon* of Johannes de Janua, a folio of 748 pages in two columns of 66 lines each, printed in 1460, but was perhaps a small glossary now lost².

The Latin Bible of 42 lines, a folio of 1282 printed pages, in two columns with spaces left for illuminated initials (so called because each column contains 42 lines, and also known as the *Mazarin Bible*, because the first copy described was found in the library of Cardinal Mazarin), was finished before Aug. 15, 1456³; German bibliographers now claim this Bible for Gutenberg, but, according to bibliographical rules, it must be ascribed to Peter Schöffer, perhaps in partnership with Fust. It is in smaller type than the Bible of 36 lines, which latter is called either (a) the *Bamberg Bible*, because nearly all the known copies were found in the neighbourhood of Bamberg, or (b) *Schelhorn's Bible*, because J. G. Schelhorn was the first who described it in 1760, or (c) *Pfister's Bible*, because its printing is ascribed to Albrecht Pfister of Bamberg, who used the same type for several small German books, the chief of which is Boner's *Edelstein* (1461, 4to), 88 leaves, with 85 woodcuts, a book of fables in German rhyme. Some bibliographers believe this 36-line Bible to have been begun, if not entirely printed, by Gutenberg during his partnership with Fust, as its type occurs in the 31-line Letters of Indulgence of 1454, was used for the 27-line Donatus (of 1451?), and, finally, when found in Pfister's possession in 1461, apparently was old and worn, except the additional letters *k*, *w*, *z* required for German, which are clear and sharp like the types used in the Bible. Again, others profess to prove (Dziatsko, *Gutenberg's früheste Druckerpraxis*) that B³⁶ was a reprint of B⁴².

Gutenberg's work, whatever it may have been, was not a commercial success, and in 1452 Fust had to come forward with another 800 guilders to prevent a collapse. But some time before November 1455 the latter demanded repayment of his advances (see the Helmasperger Notarial Document of Nov. 6, 1455, in Dziatzko's *Beiträge zur Gutenbergfrage*, Berlin, 1889), and took legal proceedings against Gutenberg. We do not know the end

¹Among these were perhaps (1) one or two editions of the work of Donatus, *De octo partibus orationis*, 27 lines to a page, of one of which two leaves, now in the Paris National Library, were discovered at Mainz in the original binding of an account book, one of them having, but in a later hand, the year 1451 (?); (2) the *Türk-Kalendar* for 1455 (preserved in the Hof-Bibliothek at Munich); (3) the *Cisianus* (preserved in the Cambridge Univ. Lib.), and perhaps others now lost.

²Ulric Zell states, in the Cologne Chronicle of 1499, that Gutenberg and Fust printed a Bible in large type like that used in missals. It has been said that this description applies to the 42-line Bible, as its type is as large as that of most missals printed before 1500, and that the size now called missal type (double pica) was not used in missals until late in the 16th century. This is no doubt true of the smaller missals printed before 1500, some of which are in even smaller type than the 42-line Bible. But many of the large folio missals, as that printed at Mainz by Peter Schöffer in 1483, the Carthusian missal printed at Spire by Peter Drach about 1490, and the Dominican missal printed by Andrea de Torresanis at Venice in 1496, are in as large type as the 36-line Bible. Peter Schöffer (1425-1502) of Gernsheim, between Mainz and Mannheim, who was a copyist in Paris in 1449, and whom Fust called his servant (*famulus*), is said by Trithemius to have discovered an easier way of founding characters, whence Lambinet and others concluded that Schöffer invented the punch. Schöffer himself, in the colophon of the Psalter of 1457, a work which some suppose to have been planned and partly printed by Gutenberg, claims only the mode of printing rubrics and coloured capitals.

³The Leipzig copy of this Bible (which formerly belonged to Herr Klemm of Dresden) has at the end the ms. year 1453 in old Arabic numerals. But certain circumstances connected with this date make it look very suspicious.

of these proceedings, but if Gutenberg had prepared any printing materials it would seem that he was compelled to yield up the whole of them to Fust; that the latter removed them to his own house at Mainz, and there, with the assistance of Peter Schöffer, issued various books until the sack of the city in 1462 by Adolphus II. caused a suspension of printing for three years, to be resumed again in 1465.

We have no information as to Gutenberg's activity, and very little of his whereabouts, after his separation from Fust. A document dated June 21, 1457, shows that he was then still at Mainz. Entries in the registers of the St. Thomas Church at Strasbourg make it clear that the annual interest on the money which Gutenberg on the 17th of November, 1442, had borrowed from the chapter of that church was regularly paid till Nov. 11, 1457, either by himself or by his surety, Martin Brechter. But the payment due on the latter date appears to have been delayed, as an entry in the register of that year shows that the chapter had incurred expenses in taking steps to have both Gutenberg and Brechter arrested. This time the difficulties seem to have been removed, but on and after Nov. 11, 1458, Gutenberg and Brechter remained in default. The chapter made various efforts, all recorded in their registers, to get their money, but in vain. Every year they recorded the arrears with the expenses to which they were put in their efforts to arrest the defaulters, till at last in 1474 (six years after Gutenberg's death) their names are no longer mentioned.

Meantime Gutenberg appears to have been *printing*, as we learn from a document dated February 26, 1468, that a syndic of Mainz, Dr. Conrad Homery (who had formerly been in the service of the elector Count Diether of Ysenburg), had at one time supplied him, not with money, but with some formes, types, tools, implements and other things belonging to printing, which Gutenberg had left after his death, and which had, and still, belonged to him (Homery); this material had come into the hands of Adolf, the archbishop of Mainz, who handed or sent it back to Homery, the latter undertaking to use it in no other town but Mainz, nor to sell it to any person except a citizen of Mainz, even if a stranger should offer him a higher price for the things. This material has never yet been identified, so that we do not know what types Gutenberg may have had at his disposal; they could hardly have included the types of the *Catholicon* of 1460, as is suggested, this work being probably executed by Heinrich Bechtermünze (d. 1467), who afterwards removed to Eltville, or perhaps by Peter Schöffer, who, about 1470, advertises the book as his property. (See K. Burger, *Buchhändler-Anzeigen*.)

It is uncertain whether Gutenberg remained in Mainz or removed to the neighbouring town of Eltville, where he may have been engaged for a while with the brothers Bechtermünze, who printed there for some time with the types of the 1460 *Catholicon*. On Jan. 17, 1465, he accepted the post of salaried courtier from the archbishop Adolf, and in this capacity received annually a suit of livery together with a fixed allowance of corn and wine. Gutenberg seems to have died at Mainz at the beginning of 1468, and was, according to tradition, buried in the Franciscan church in that city. No books bearing the name of Gutenberg as printer are known, nor is any genuine portrait of him known, those appearing upon medals, statues or engraved plates being all fictitious.

In 1898 the firm of L. Rosenthal, at Munich, acquired a *Missale speciale* on paper, which Otto Hupp, in two treatises published in 1898 and 1902, asserts to have been printed by Gutenberg about 1450, seven years before the 1457 Psalter. Various German bibliographers, however, think that it could not have been printed before 1480, and, judging from the facsimiles published by Hupp, this date seems to be approximately correct.

In 1902 a vellum fragment of an Astronomical Kalendar was discovered by the librarian of Wiesbaden, Dr. G. Zedler (*Die älteste Gutenbergtype*, Mainz, 1902), apparently printed in the 36-line Bible type, and as the position of the sun, moon and other planets described in this document suits the years 1429, 1448 and 1467, he ascribes the printing of this Kalendar to the year 1447. A paper fragment of a poem in German, entitled *Weltgericht*, said

to be printed in the 36-line Bible type, appears to have come into the possession of Herr Eduard Beck at Mainz in 1892, and was presented by him in 1903 to the Gutenberg Museum in that city. Zedler published a facsimile of it in 1904 (for the *Gutenberg Gesellschaft*), with a description, in which he places it before the 1447 *Kalendar*, c. 1444–1447. Moreover, fragments of two editions of Donatus different from that of 1451 (?) have recently been found; see Schwenke in *Centralbl. für Bibliothekswesen* (1908).

GÜTERSLOH, a town in the Prussian province of Westphalia, 11 m. S.W. from Bielefeld by the railway to Dortmund. Pop. (1925) 22,138. It is a seat of the cotton industry, and has a large trade in Westphalian hams and sausages. Printing, brewing and distilling are also carried on, and the town is famous for its rye-bread (*Pumpernickel*).

GUTHRIE, SIR JAMES (1859–), Scottish painter, and one of the leaders of the Glasgow School, was born at Greenock. In his early works, such as "The Gipsy Fires are Burning, for Daylight is Past and Gone" (1882), and the "Funeral Service in the Highlands," he favoured a thick impasto, but with growing experience he used his colour with greater economy and reticence. Subsequently he devoted himself almost exclusively to portraiture. He was elected A.R.S.A. in 1888, R.S.A. in 1892, P.R.S.A. in 1902, and was knighted in 1903. He was trustee of the National Galleries of Scotland from 1906 to 1920. His painting "School-mates" is at the Ghent gallery. Among his most successful portraits are those of his mother, Major Hotchkiss, Professor Jack, and Mrs. Watson.

GUTHRIE, THOMAS ANSTEY (1856–), known by the pseudonym of F. Anstey, English novelist and playwright, was born in Kensington, London. He was educated at King's college, London, and at Trinity Hall, Cambridge, and was called to the bar in 1880. The popular success of his story *Vice-Versa* (1882), with its topsy-turvy substitution of a father for his schoolboy son, made his reputation, which was further confirmed by *The Black Poodle* (1884), *The Tinted Venus* (1885), *The Fallen Idol* (1886) and other works. On the stage his best piece was *The Man from Blankley's* (1901).

GUTHRIE, a city of Oklahoma, U.S.A., near the Cimarron river, 30m. N. of Oklahoma city, the county seat of Logan county. It is on Federal highway 77, has an airport (50ac.) and is served by the Fort Smith and Western, the Oklahoma (electric) and the Santa Fe railways. The population was 11,757 in 1920 (20% negroes), and was estimated locally at 15,000 in 1928. Guthrie is the trade centre for a large and productive agricultural region, specializing chiefly in fruit, poultry-raising and dairying. It has sundry manufacturing industries (with an output in 1925 valued at \$1,241,367) including the first cotton mill established in the State. There are several deep mineral springs in the city, and numerous oil-wells in the county. Guthrie was founded in 1889, when Oklahoma was opened to settlement. It was the capital of the territory and the State from 1890 to 1910.

GUTHRUM (GODRUM) (d. 890), king of East Anglia, first appears in the *English Annals* in the year 875, when he is mentioned as one of three Danish kings who went with the host to Cambridge. He was probably engaged in the campaigns of the next three years, and after Alfred's victory at Edington in 878, Guthrum met the king at Aller in Somersetshire and was baptized there under the name of Aethelstan. He stayed there for twelve days and was greatly honoured by his godfather Alfred. In 890

Guthrum-Aethelstan died: he is then spoken of as "se norðerna cyning" (probably) "the Norwegian king," referring to the ultimate origin of his family, and we are told that he was the first (Scandinavian) to settle East Anglia. Guthrum is perhaps to be identified with Gormr (=Guthrum) hinn heimski or hinn riki of the Scandinavian sagas, the foster-father of Hörðaknutr, the father of Gorm the old. There is a treaty known as the peace of Alfred and Guthrum. For details of the struggle with the English see ALFRED.

GUTSCHMID, ALFRED, BARON VON (1835-1887), German historian and orientalist, was born on July 1, 1835 as Loschwitz (Dresden). After holding chairs at Kiel (1866), Königsberg (1873), and Jena (1876), he was finally appointed professor of history at Tübingen, where he died on March 2, 1887. He devoted himself to the study of Eastern language and history in its pre-Greek and Hellenistic periods and contributed largely to the literature of the subject. Of his numerous works the best-known is his *Geschichte Irans* (Alexander the Great to the fall of the Arsacidae) (Tübingen, 1887). He wrote on Persia and Phoenicia in the 9th edition of the *Encyclopædia Britannica*. (See LANGUAGE AND WRITING.)

A collection of minor works entitled *Kleine Schriften* was published by F. Rühl at Leipzig (1889-94, 5 vols.), with complete list of his writings.

GUTS-MUTHS, JOHANN CHRISTOPH FRIEDRICH (1759-1839), German teacher and the principal founder of the German school system of gymnastics, was born at Quedlinburg on Aug. 9, 1759, and died on May 31, 1839. It was chiefly through his books on the subject that gymnastics came to occupy such an important position in the school system of Germany.

His principal works are *Gymnastik für die Jugend* (1793); *Spiele zur Übung und Erholung des Körpers und Geistes für die Jugend* (1796); *Turnbuch* (1817); *Handbuch der Geographie* (1810); and a number of books constituting a *Bibliothek für Pädagogik, Schulwesen, und die gesammte pädagogische Literatur Deutschlands*.

GUTTA, in architecture, one of the small, conical or cylindrical forms carved on the under side of the mutules (q.v.), or flat projections on the under side of the Doric cornice; they also appear beneath the upper member of the architrave (q.v.), directly below each triglyph (q.v.).

neath the upper member of the architrave (q.v.), directly below each triglyph (q.v.).

GUTTA PERCHA, the name applied to the evaporated milky fluid or latex furnished by several trees chiefly found in the islands of the Malay Archipelago.

Botanical Origin and Distribution.—The best gutta percha of Malaya was chiefly derived from two trees belonging to the family Sapotaceae. They are *Palaquium Gutta*, now no longer cultivated and *P. oblongifolia*. Allied trees of the same genus and of the same family yield similar but usually inferior products. Among them may be mentioned species of *Payena*.

Gutta percha trees often attain a height of 70 to 100 ft. and the trunk has a diameter of from 2 to 3 feet. They are stated to be mature when about thirty years old. The leaves of *Palaquium*, which are obovate-lanceolate, with a distinct pointed apex, occur in clusters at the end of the branches, and are bright green and smooth on the upper surface but on the lower surface are yellowish-brown and covered with silky hairs. The leaves are usually about 6 in. long and about 2 in. wide at the centre. The flowers are white, and the seeds are contained in an ovoid berry about 1 in. long.

The gutta percha tree is almost entirely confined to the Malay Peninsula and its immediate neighbourhood. It includes a region within 6 degrees north and south of the equator and 93°-119° longitude, where the temperature ranges from 66° to 90° F and the atmosphere is exceedingly moist. The trees may be grown from seeds or from cuttings.

Preparation of Gutta Percha.—The gutta is furnished by the greyish milky fluid, the latex, chiefly secreted in cylindrical vessels or cells in the cortex. Latex also occurs in the leaves of the tree and may be removed from the powdered leaves by the use of appropriate solvents, but the process is not practicable commercially. The latex flows slowly where an incision is made through

the bark, but not nearly so freely as the india-rubber latex. On this account the Malays usually fell the tree to collect the latex, which is done by chopping off the branches and removing circles of the bark, forming cylindrical channels about an inch wide at various points about a foot apart down the trunk. The latex exudes and fills these channels, from which it is removed and converted into gutta by boiling in open vessels over wood fires. The work is usually carried on in the wet season when the latex is more fluid and more abundant. Sometimes when the latex is thick water is added before boiling. The best results are said to be obtained from mature trees which furnish about 2 to 3 lb. of gutta.

The Chinese and Malays appear to have been acquainted with the characteristic property of gutta percha of softening in warm water and of regaining its hardness when cold, but this plastic property seems to have been utilized only for ornamental purposes, the construction of walking-sticks, of knife handles and whips, etc. The brothers Tradescant brought samples of the curious material to Europe about the middle of the 17th century.

Characters and Properties.—Gutta percha appears in commerce in the form of blocks or cakes of a dirty greyish appearance, often exhibiting a reddish tinge, and just soft enough to be indented by the nail. It is subject to considerable adulteration. It is solid, fibrous in texture, hard and inelastic, but not brittle at ordinary temperature, becomes plastic when immersed in hot water or otherwise raised to a temperature of about 65°-66° C. in the case of gutta of the first quality, the temperature of softening being dependent on the quality of the gutta employed. In this condition it can be drawn out into threads, but is still inelastic. On cooling again the gutta resumes its hardness without becoming brittle. In this respect gutta percha differs from india-rubber or caoutchouc, which does not become plastic and unlike gutta percha is elastic. This property of softening on heating and solidifying when cooled again, without change in its original properties, enables gutta percha to be worked into various forms, rolled into sheets or drawn into ropes. The specific gravity of the best gutta percha lies between 0.96 and 1. Gutta percha is dissolved by the liquids which dissolve rubber such as carbon disulphide and chloroform, and light petroleum when hot. Gutta percha is not affected by alkaline solutions or by dilute acids. Strong sulphuric acid chars it when warm, and nitric acid effects complete oxidation. When exposed to air and light, gutta percha rapidly deteriorates, oxygen being absorbed, producing a brittle resinous material.

Chemical Composition.—Chemically, gutta percha is a mixture of several constituents. The proportions in the crude material are not constant. For electrical purposes it should have a high insulating power and dielectric strength and a low inductive capacity; the possession of these properties is influenced by the resinous constituents present.

The principal constituent of the crude material is a hydrocarbon of the empirical formula C_5H_8 . It is therefore isomeric with the hydrocarbon of caoutchouc. Accompanying this are at least two oxygenated resinous constituents—albanes and fluavils—which can be separated from the gutta by solvents. Pure gutta is not dissolved by ether and light petroleum in the cold, whereas the resinous constituents are removed by these liquids. The true gutta exhibits in an enhanced degree the valuable properties of gutta percha, and the commercial value of the raw material is frequently determined by ascertaining the proportion of true gutta percha. When distilled at a high temperature, gutta percha like india-rubber is resolved into a mixture of simpler hydrocarbons, isoprene (C_5H_8) and hydrocarbons of higher boiling point containing $C_{10}H_{16}$ and $C_{30}H_{48}$. Alban has been described as a mixture of resins, white in colour and soluble in hot alcohol. Fluavil is a yellow amorphous resin which dissolves in cold alcohol.

Trade in Gutta Percha.—The imports of gutta percha and balata into the United Kingdom for home consumption in recent years have been in centals of 100 lb., as follows:

1925 . . . 96,300	1926 . . . 74,700	1927 . . . 42,000
-------------------	-------------------	-------------------

The fall in imports shown in these figures was continued in 1928.

GUTTER, in architecture, a horizontal channel or trough contrived to carry away the water from a flat or sloping roof to its discharge down a vertical pipe or through a spout or gargoyle; more specifically, but loosely, the similar channel at the side of a street. In Greek and Roman temples the cymatium of the cornice was the gutter, and the water was discharged through the mouths of carved lions' heads. In mediaeval work the gutter rested on the top of the wall or on a corbel table, and the water was discharged through gargoyles. Sometimes, however, a parapet or pierced balustrade was carried outside the gutter. In many buildings the parapet is only a continuation of the wall below, and the gutter is set back and carried in a trough resting on the lower end of the roof timbers. The most practical form is an eaves gutter which projects more or less in front of the wall and is secured to and carried by the rafters of the roof. In French Renaissance work the gutter is frequently concealed behind a rich cresting in stone, lead or copper at the edge of the main cornice. (See also LIGHT CASTINGS INDUSTRY.)

GUTZKOW, KARL FERDINAND (1811–1878), German novelist and dramatist, was born on March 17, 1811 at Berlin. In 1832 he published anonymously at Hamburg his *Briefe eines Narren an eine Närrin*, and in 1833 appeared at Stuttgart *Maha-Guru, Geschichte eines Gottes*, a fantastic and satirical romance. In 1835 he went to Frankfurt, where he founded the *Deutsche Revue*. In the same year appeared *Wally, die Zweiflerin*, an attack on marriage which marks the beginning of the revolt of "Young Germany" against romanticism. He was violently attacked by Wolfgang Menzel (*q.v.*), and the Federal Diet condemned Gutzkow to three months' imprisonment and decreed the suppression of all he had written or might yet write. During his term of imprisonment at Mannheim, Gutzkow wrote his treatise *Zur Philosophie der Geschichte* (1836). On his release he produced *Richard Savage* (1839), a play which immediately made the round of all the German theatres. Of his numerous other plays a few have kept a place in the German repertory. In 1847 Gutzkow went to Dresden, where he succeeded Tieck as literary adviser to the court theatre. Meanwhile he had written the novels *Seraphine* (1838) and *Blasedow und seine Söhne* (1838), a satire on the educational theories of the time. Between 1850 and 1852 appeared *Die Ritter vom Geiste*, which may be regarded as the starting-point for the modern German social novel. *Der Zauberer von Rom* is a powerful study of Roman Catholic life in southern Germany. Gutzkow then established a journal on the model of Dickens' *Household Words*, entitled *Unterhaltungen am häuslichen Herd* (1852–62). He died on Dec. 16, 1878. Gutzkow exerted a powerful influence on the opinions of modern Germany; and his works reflect the intellectual and social struggles of his time.

An edition of Gutzkow's collected works appeared at Jena (1873–76, new ed., 1879). E. Wolff has published critical editions of Gutzkow's *Meisterdramen* (1892) and *Wally die Zweiflerin* (1905). His more important novels have been frequently reprinted. For Gutzkow's life see his various autobiographical writings such as *Aus der Knabenzeit* (1852), *Rückblicke auf mein Leben* (1876), etc. For an estimate of his life and work see J. Proelss, *Das junge Deutschland* (1892); H. H. Houben, *Studien über die Dramen Gutzkows* (1898); *Gutzkow-Funde* (1901), and other monographs on various aspects of Gutzkow; E. Metis, *Karl Gutzkow als Dramatiker* (1915).

GÜTZLAFF, KARL FRIEDRICH AUGUST (1803–1851), German missionary to China, was born at Pyritz in Pomerania on July 8, 1803. After serving as a missionary in Java and Siam, he went to China, and there translated the Bible into Chinese, published a Chinese monthly magazine, and wrote in Chinese various books on subjects of useful knowledge. In 1834 he published a *Journal of Three Voyages along the Coast of China in 1831, 1832 and 1833*. He was appointed in 1835 joint Chinese secretary to the English commission, and during the opium war of 1840–42 and the negotiations connected with the peace his knowledge of the country and people made him extremely useful. Gützlaff in 1844 founded an institute for training native missionaries. He died at Hong Kong on Aug. 9, 1851.

Gützlaff also wrote *A Sketch of Chinese History, Ancient and Modern* (London, 1834), and a similar work published in German at Stuttgart in 1847; *China Opened* (1838); and the *Life of Taow-*

Kwang (1851; German edition published at Leipzig in 1852). There is a complete collection of his Chinese writings in the Munich library.

GUY, THOMAS (1644–1724), founder of Guy's hospital, London, was the son of a lighterman and coal-dealer at Southwark. After an apprenticeship of eight years with a bookseller, he, in 1668, began business on his own account. He dealt largely in Bibles, which were poorly and incorrectly printed in England. These he at first imported from Holland, but subsequently obtained from the University of Oxford the privilege of printing. He died on Dec. 17, 1724. In 1707 he built three wards of St. Thomas's hospital. He erected Guy's hospital, leaving for its endowment £219,449, and endowed other charities. He was M.P. for Tamworth from 1695 to 1707.

See *A True Copy of the Last Will and Testament of Thomas Guy, Esq.* (1725); C. Knight, *Shadows of the Old Booksellers*, pp. 3–23 (1865); S. Wilkes and G. T. Bettany, *A Biographical History of Guy's Hospital* (1892).

GUYAU, JEAN MARIE (1854–1888), French philosopher, was born on Oct. 28, 1854, at Laval and died on March 31, 1888, at Mentone. Ill-health required him to resign his professorship at the Lycée Condorcet and to live in the French Sudan where he devoted himself to questions of aesthetics, ethics and religious philosophy. His chief works are: *Mémoire sur la Morale utilitaire, depuis Epicure jusqu'à l'école anglaise* (1878, 7th ed. 1913); *Esquisse d'une morale sans obligation ni sanction* (1885, 2nd. ed. 1890) and *L'irréligion de l'avenir* (1887, 7th ed. 1904).

See H. Höffding, *Modern Philosophers* (1905); G. Aslan, *La morale selon Guyau* (1906); and E. Bergmann, *Die Philosophie Guyaus* (1912).

GUYNEMER, GEORGES (1894–1917), French aviator, born in Paris on Dec. 24, 1894, was the most famous of all the aviators on the French side in the World War. His courage, his gaiety, his 53 victories over enemy aviators, and his death in a battle in the air above Poelcapelle on Sept. 11, 1917, made him a popular hero. For the story of his brief life see H. Bordeaux, *Le chevalier de l'air, Guynemer* (1919).

GUY OF WARWICK, English hero of romance. Guy, son of Siward or Seguard of Wallingford, by his prowess in foreign wars wins in marriage Félice (the Phyllis of the well-known ballad), daughter and heiress of Roalt, earl of Warwick. Soon after his marriage, seized with remorse for the violence of his past life, he leaves his wife and fortune to make a pilgrimage to the Holy Land. After years of absence he returns in time to deliver Winchester for King Aethelstan from the invading northern kings, Anelaph (Anlaf or Olaf) and Gonelaph, by slaying in single fight their champion, the giant Colbrand. Local tradition fixes the duel at Hyde Mead near Winchester. Making his way to Warwick he becomes one of his wife's bedesmen, and retires to a hermitage in Arden, only revealing his identity at the approach of death. The versions of the Middle English romance of Guy which we possess are adaptations from the French, and open with a long recital of Guy's wars in Lombardy, Germany and Constantinople. The kernel of the tradition evidently lies in the fight with Colbrand, which may represent an historical fact. If so, the Anlaf of the story is probably Olaf Trygvason, who, with Sweyn of Denmark, harried the southern counties of England in 993 and pitched his winter quarters in Southampton. Winchester was saved, however, not by the valour of an English champion, but by the payment of money. This Olaf was not unnaturally confused with Anlaf Cuaran or Havelok (*q.v.*). Guy's Cliffe, near Warwick, where in the 14th century Richard de Beauchamp, earl of Warwick, erected a chantry, with a statue of the hero, does not correspond with the site of the hermitage as described in the romance. The bulk of the legend is obviously fiction.

The French romance (Harl. ms. 3,775) is described by Émile Littré in *Hist. litt. de la France* (xxii., 841–851, 1852). A French prose version was printed in Paris, 1525, and subsequently (see G. Brunet, *Manuel du libraire*, s.v. "Guy de Warwick"); the English metrical romance exists in four versions, dating from the early 14th century; the text was edited by J. Zupitza (1875–76) for the E.E.T.S. (extra series, Nos. 42, 49, 59). The popularity of the legend is shown by the numerous versions in English, such

as *Guy of Warwick*, translated from the Latin of Girardus Cornubiensis (fl. 1350) into English verse by John Lydgate between 1442 and 1468. See also an article by S. L. Lee in the *Dictionary of National Biography*.

GUYON, JEANNE MARIE BOUVIER DE LA MOTHE (1648–1717), French quietist writer, was born of good family at Montargis on April 13, 1648. She attended various convent schools, and in 1664 married a rich invalid of the name of Guyon, many years her senior. Twelve years later he died, leaving his widow with three small children and a considerable fortune.

Her attraction towards the mystical life was developed by her spiritual director, Father Lacombe, a Barnabite monk of weak character and unstable intellect, and from 1681 the two rambled about together in Savoy and the south-east of France, spreading their mystical ideas. At last they excited the suspicion of the authorities; in 1686 Lacombe was recalled to Paris, put under surveillance, and was finally sent to the Bastille in 1687. He was presently transferred to the castle of Lourdes, where he died in 1715.

Meanwhile Madame Guyon had been arrested in 1688, but was delivered in the following year by her old friend, the duchesse de Béthune, who had become a power in the devout court-circle presided over by Madame de Maintenon. Before long Madame Guyon herself was introduced into this pious assemblage where she displayed her charm and eloquence. She became friendly with Fénelon, now a rising young spiritual director. Between 1689 and 1693 they corresponded regularly.

Meanwhile similar reports had strained her relationship with Madame de Maintenon, and to clear her orthodoxy, Madame Guyon appealed to Bossuet, who decided that her books contained "much that was intolerable, alike in form and matter." Madame Guyon promised to "dogmatize no more," and disappeared into the country (1693). In the next year she again petitioned for an inquiry, and was eventually sent to Bossuet's cathedral town of Meaux. She soon left without his leave, bearing with her a certificate of orthodoxy signed by him. Bossuet regarded this flight as an act of disobedience; in the winter Madame Guyon was arrested and shut up in the Bastille. There she remained till 1703. In that year she was liberated, on condition she would live on her son's estate near Blois, under the eye of a stern bishop. Here the rest of her life was spent in charitable and pious exercises; she died on June 9, 1717. In France she has often been reckoned an hysterical degenerate; in England and Germany she has as often roused enthusiastic admiration.

BIBLIOGRAPHY.—Mme. Guyon's complete works appeared in 40 vols. (1767–91). There are English translations of her autobiography by T. T. Allen (2 vols., 1897), of her *Spiritual Torrents* by A. W. Marston (1908), of her *Mystical Sense of Sacred Scriptures* by T. W. Duncan (1872), of her *Method of Prayer* by D. Macfadyen (1902) and of her select poems by W. Cowper (1801). See T. C. Upham, *Life of Mme. Guyon* (new ed., 1905); M. Masson, *Fénelon et Mme. Guyon, Documents nouveaux et inédits* (1907) and E. Seillière, *Mme. Guyon et Fénelon* (1918). See also QUIETISM; and H. Delacroix, *Études d'histoire et de psychologie sur le mysticisme* (Paris, 1908).

GUYON, RICHARD DEBAUFRE (1803–1856), British soldier, general in the Hungarian revolutionary army and Turkish pasha, was born at Walcot, near Bath, in 1803. After receiving a military education in England and in Austria he entered the Hungarian hussars in 1823. At the outbreak of the Hungarian War in 1848, he re-entered active service as an officer of the Hungarian Honvéds, and he won great distinction in the action of Sukoro (Sept. 29, 1848) and the battle of Schwechat (Oct. 30). He served in important and sometimes independent commands to the end of the war, after which he escaped to Turkey. In 1852 he entered the service of the sultan. He was made a pasha and lieutenant-general without being required to change his faith, and fought in the campaign against the Russians in Asia Minor (1854–55). General Guyon died of cholera at Scutari on Oct. 12, 1856.

See A. W. Kinglake, *The Patriot and the Hero General Guyon* (1856).

GUYOT, ARNOLD HENRY (1807–1884), Swiss-American geologist and geographer, was born at Boudevilliers, near Neu-

châtel, Switzerland, on Sept. 28, 1807. Before coming to the United States in 1848, he studied at the college of Neuchâtel and in Germany, where he began a lifelong friendship with Louis Agassiz. He was professor of geology and physical geography at Princeton from 1854 until his death on Feb. 8, 1884. He was ranked high as a geologist and meteorologist. His extensive meteorological observations in America led to the establishment of the U.S. weather bureau, and his *Meteorological and Physical Tables* (1852, revised edition 1884) were long standard. His text books and wall maps aided in popularizing and extending geological study in America.

As early as 1838 he undertook, at Agassiz's suggestion, the study of glaciers, from which he announced for the first time certain important observations relating to glacial motion and structure. Among other things he noted the more rapid flow of the centre than of the sides, and the more rapid flow of the top than of the bottom of glaciers; described the laminated or "ribboned" structure of the glacial ice, and ascribed the movement of glaciers to a gradual molecular displacement rather than to a sliding of the ice mass as held by de Saussure. He subsequently collected important data concerning erratic boulders.

His principal publications, in addition to text books, were: *Earth and Man, Lectures on Comparative Physical Geography in its Relation to the History of Mankind* (translated by Professor C. C. Felton, 1849); *A Memoir of Louis Agassiz* (1883); and *Creation, or the Biblical Cosmogony in the Light of Modern Science* (1884).

See James D. Dana's "Memoir" in the *Biographical Memoirs of the National Academy of Science*, vol. ii. (Washington, 1886).

GUYOT, YVES (1843–1928), French politician and economist, was born at Dinan on Sept. 6, 1843. Educated at Rennes, he took up the profession of journalism, coming to Paris in 1867. He was for some time editor-in-chief of *L'Indépendant du midi* of Nîmes, joined the staff of *La Rappel* on its foundation, and worked on other journals. He waged a keen campaign against the prefecture of police, for which he suffered six months' imprisonment. He entered the chamber of deputies in 1885 as representative of the first arrondissement of Paris and was *rapporteur général* of the budget of 1888. He was minister of public works from 1889 to 1892. He lost his seat in the election of 1893 owing to his militant attitude against Socialism. An uncompromising free-trader, he published *La Comédie protectionniste* (1905; Eng. trans. *The Comedy of Protection*); *La Science économique* (1st ed. 1881; 3rd ed. 1907); *La Prostitution* (1882); *La Tyrannie socialiste* (1893), all three translated into English; *Les Conflits du travail et leur solution* (1903); *La Démocratie individualiste* (1907). Other important works are *Études de physiologie sociale* (6 vols., 1882–1905), and *La Gestion par l'état et les municipalités* (1913). Guyot died on Feb. 21, 1928.

GUYTON DE MORVEAU, LOUIS BERNARD, BARON (1737–1816), French chemist, was born on Jan. 4, 1737, at Dijon. He studied law at Dijon, and became advocate-general in the *parlement*, until 1782. He devoted his leisure to chemistry, and in 1772 published *Digressions académiques*, containing his views on phlogiston, crystallization, etc. An essay on chemical nomenclature in the *Journal de physique* for May 1782 was developed, with the aid of A. L. Lavoisier, C. L. Berthollet and A. F. Fourcroy, into the *Méthode d'une nomenclature chimique* (1787), the principles of which were adopted by chemists throughout Europe. He adopted Lavoisier's views on combustion and published his reasons in the first volume of the section "Chymie, Pharmacie et Metallurgie" of the *Encyclopédie méthodique* (1786), the chemical articles in which were written by him. In 1791 he was elected member of the Legislative Assembly, and in 1792 and 1795 of the Convention. He was master of the mint from 1800 to 1814. In 1811 he was made baron of the French empire. He died in Paris on Jan. 2, 1816.

In addition to many scientific papers, Guyton wrote *Mémoire sur l'éducation publique* (1762); a satirical poem entitled *Le Rat iconoclaste, ou le Jésuite croqué* (1763); *Discours publics et éloges* (1775–82); *Plaidoyers sur plusieurs questions de droit* (1785); and *Traité des moyens de désinfecter l'air* (1801), describing the disinfecting powers of chlorine, and of hydrochloric acid gas which he had successfully used at Dijon in 1773. With Hugues Maret (1726–1785) and Jean François Durande (d. 1794) he also published the *Éléments de chymie théorique et pratique* (1776–1777).

GUZMÁN BLANCO, ANTONIO (1829-1899), Venezuelan soldier and statesman, was born on Feb. 29, 1829, in Carácas, Venezuela, where his father, Antonio Leocardio Guzmán, had held important offices in the Governments of Bolívar and Páez. Guzmán Blanco received the degree of licenciado of jurisprudence in the university, and afterwards travelled in the United States, where he represented his country in several capacities, notably as secretary to the Venezuelan legation in Washington. In 1859 he returned to Venezuela to take part in a revolution under Gen. Falcón which was finally successful in 1863. Under the new Government he was vice president, minister of the treasury and minister for foreign affairs. During the period from 1863 to 1868 he acted several times as president *ad interim*, as commander of the army, and as special finance commissioner to Europe, and displayed in each capacity extraordinary energy and ability. In 1868, while he was in Europe, the Falcón Government was overthrown. In Feb. 1870, he headed a counter revolt, set up a dictatorship (April 1870) and after more than two years of civil war, was elected constitutional president on Feb. 20, 1873. Re-elected in 1880, 1882 and 1886, though frequently away, he retained absolute control of the Government until 1888.

Guzmán Blanco's rule was arbitrary, his policy was corrupt and his methods were harsh, but under his régime, Venezuela experienced a renaissance. He reorganized the Government, asserted the national prestige, enforced security of life and property, placed the finances on a sound footing, broke the power of the church, established primary education, sponsored immigration, constructed railways and roads and spent immense sums on public works. A revolt broke out, however, against him in the capital in 1889, during the presidency of Rojas-Paul. Guzmán Blanco was in Europe, the Government repudiated his authority and the army deserted him. He never returned to Venezuela, and on July 30, 1899, died in Paris.

No authoritative life of Guzmán Blanco has yet appeared but interesting chapters on the man and his career will be found in: W. E. Curtis' *Venezuela* (New York, 1896); and Alfred Deberle's *The History of South America* (New York, 1899). (W. B. P.)

GUZMICS, IZIDOR (1786-1839), Hungarian theologian, was born on April 7, 1786, at Vámos-Család. He became a Benedictine, and after studying at Pesth, in 1816 settled at the monastery at Pannonhegy, where he devoted himself to dogmatic theology and literature, and contributed largely to Hungarian periodicals. In 1832 he was appointed abbot at Bakonybél. He died on Sept. 1, 1839. Guzmics' chief work is *Theologia Christiana fundamentalis et theologia dogmatica* (4 vols., Győr, 1828-29).

GWADUR, a port on the Mekran coast of Baluchistan, about 290 m. W. of Karachi. Pop. (1903) 5,000. In the last half of the 18th century it was handed over by the khan of Kalat to the sultan of Muscat, who still exercises sovereignty over the port, together with about 300 sq.m. of the adjoining country. It is a place of call for the steamers of the British India Steam Navigation Company.

GWALIOR, one of the five leading Indian States, and the dominion of the Sindhia family of Mahrattas. The State consists of two well-defined parts which may roughly be called the northern and the southern. The former is a compact mass of territory, bounded north and north-west by the Chambal river, and wedged in between Rajputana and British territory. The southern, or Malwa, portion is made up of detached or semi-detached districts, between which are interposed parts of other States, which again are mixed up with each other in bewildering intricacy. The two portions have a total area of 26,357 sq.m. Pop. (1921), 3,186,075.

Physical Characters.—The State may be divided into plain, plateau and hilly country. The plain country extends from the Chambal river southwards for about 80 m., with a maximum width from east to west of about 120 miles. This plain, though broken in its southern portion by low hills, has generally an elevation of only a few hundred feet above sea-level, and endures great heat, though the rainfall is good. South of this tract there is a gradual ascent to the Central India plateau, and at Sipri the general level is 1,500 ft. above the sea; the elevation giving this

region a moderate climate during the summer as compared with the plain country, while the winter is warmer and more equable. The hilly portion of the State lies in the Bhil country and comprises only the small district of Amjhara, among the Vindhya mountains. Of these three natural divisions the plateau possesses the most fertile soil, generally of the kind known as "black cotton," but the low-lying plain has the densest population. The State is watered by numerous rivers. The Nerbudda, flowing west, forms the southern boundary. The greater part of the drainage is discharged into the Chambal, which forms the north-western and northern and eastern boundary. The Sind, with its tributaries the Kuwari, Asar and Sankh, flows through the northern division.

Crops and Industries.—The chief products are wheat, millets, pulses of various kinds, maize, rice, linseed and other oil-seeds, sugar-cane, cotton, tobacco, indigo, garlic, turmeric and ginger. The chief industry is cotton, and the State abounds in gins, presses and spinning factories. The late maharajah pursued an enlightened policy of developing the economic wealth of his State, by the encouragement of industries, the establishment of a fine irrigation system, and a network of light railways. The revenue of the State is about £1,400,000, and it lent three millions to the Government of India for railway construction. The State maintains a large force of imperial service troops, and the late maharajah saw service in the expedition to China. The present ruler is a minor; his salute is 21 guns.

Buildings.—Commanding the city and surrounding country is the magnificent fort, one of the most impressive of the mediaeval strongholds in India. It crowns a precipitous isolated rock of sandstone, about 1½ m. in length, but at no point more than 900 yd. broad, and averaging about 300 ft. in height. Its military strength is written in its long and chequered history; its chief interest now lies in the group of splendid palaces and temples which have grown up within its walls, and in the marvellous Jain sculptures on the rock-face below them. Of the palaces, that which was built by Man Singh (1486-1516) exemplifies the best Hindu architecture of its class in India. Its massive towers and latticed battlements vie in beauty with the internal scheme of decoration in enamelled tiles. The Karan palace, which adjoins it, is singularly interesting in the devices which the Hindu architect adopted to secure the effect of the Mohammedan vault, its domed roof being supported on eight carved ribs, which intersect and form a flat square. Between these two lies a third Hindu palace, and two others of less interest were added by Delhi emperors. The group is unequalled for picturesque beauty by anything in central India. Of the temples, the pair known as *Sas-bahn* (mother-in-law and daughter-in-law), date from A.D. 1093, and stand on richly carved plinths. The *Teli-ka-Mandir* (oilman's temple) is 11th century work, and was originally constructed as a Vishnavite shrine, but was afterwards converted to Saivite uses.

Of the Jain remains, the most striking are the unique series of sculptures excavated out of the solid rock under the fortress. There are caves and caverns, often occupied by ascetics; deep niches for statues; and several groups of gigantic figures. One colossus is 57 ft. high; and the south-west group, occupying half-a-mile of cliff, has a number of figures from 20 to 30 ft. in height. From the accompanying inscriptions they appear to have been all constructed between A.D. 1441 and 1474, and they were badly mutilated 50 years later by order of the emperor Baher. The city consists of the old town, lying under the north end of the rock, and the new town of Lashkar to the south of the fort.

The old town is in decay, but has a beautiful mosque and the tomb of Ghaus Mohammed, a fine specimen of early Mogul architecture. Lashkar dates from the beginning of the 19th century, and has some handsome streets and buildings. Besides the maharaja's palaces and the houses of the chief nobles, there are the Victoria college, hospitals for men and women, a museum, paper mills and a printing press. A few miles east of the fort is the cantonment of Movar. Like the fort, it used to be garrisoned by British troops, but in 1886 was handed over to Gwalior in exchange for Jhansi fort and a strip of territory along the west of the Jhansi district. The population of the city as a whole was 80,387 in 1921.

History.—The Sindhia family, the rulers of the Gwalior state, belong to the Mahratta nation. Their first appearance in Central India was early in the 18th century in the person of Ranoji (d. 1745). In 1726, together with Malhar Rao Holkar, the founder of the house of Indore, he was authorized by the peshwa to collect tribute (*chauth*) in the Malwa districts. He established his headquarters at Ujjain, which thus became the first capital of Sindhia's dominions.

Ranoji's son and successor, Jayapa Sindhia, was killed at Nagaur in 1759, and was succeeded by his son Jankoji Sindhia. But the real founder of the state of Gwalior was Mahadji Sindhia, a natural son of Ranoji, who, after narrowly escaping with his life from the terrible slaughter of Panipat in 1761 (when Jankoji was killed), obtained a re-grant of his father's possessions in Central India (1769). During the struggle which followed the death of Madhu Rao Peshwa in 1772 Mahadji seized every occasion for extending his power and possessions. In 1775, however, when Raghuba Peshwa threw himself on the protection of the British, the reverses which Mahadji encountered at their hands—Gwalior being taken by Major Popham in 1780—opened his eyes to their power. By the treaty of Salbai (1782) it was agreed that Mahadji should withdraw to Ujjain, and the British retire north of the Jumna. Mahadji, who undertook to open negotiations with the other belligerents, was recognized as an independent ruler, and a British resident was established at his court. Mahadji, aided by the British policy of neutrality, now set to work to establish his supremacy over Hindustan proper. Mahadji's disciplined troops made him invincible. In 1785 he re-established Shah Alam on the imperial throne at Delhi. In 1788 he took advantage of the cruelties practised by Ghulam Kadir on Shah Alam, to occupy Delhi, where he established himself as the protector of the aged emperor. Though nominally a deputy of the peshwa he was now ruler of a vast territory, including the greater part of Central India and Hindustan proper, while his lieutenants exacted tribute from the chiefs of Rajputana.

Mahadji died in 1794, and was succeeded by his adopted son, Daulat Rao Sindhia, a grandson of his brother Tukoji. When, during the period of unrest that followed the deaths of the peshwa, Madhu Rao II., in 1795 and of Tukoji Holkar in 1797, the Mahratta leaders fought over the question of supremacy, the peshwa, Baji Rao II., the titular head of the Mahratta confederation, fled from his capital and placed himself under British protection by the treaty of Bassein (December 31, 1802). This interposition of the British government was resented by the confederacy, and it brought on the Mahratta War of 1803. In the campaign that followed a combined Mahratta army, in which Daulat Rao's troops furnished the largest contingent, was defeated by General Arthur Wellesley at Assaye and Argaum in Central India; and Lord Lake routed Daulat Rao's European-trained battalions in Northern India at Agra, Aligarh and Laswari. Daulat Rao was then compelled to sign the treaty of Sarji Anjangaon (December 30, 1803), which stripped him of his territories between the Jumna and Ganges, the district of Broach in Gujarat and other lands in the south. By the same treaty he was deprived of the forts of Gwalior and Gohad; but these were restored by Lord Cornwallis in 1805, when the Chambal river was made the northern boundary of the state. By a treaty signed at Burhanpur in 1803 Daulat Rao further agreed to maintain a subsidiary force, to be paid out of the revenues of the territories ceded under the treaty of Sarji Anjangaon. When, however, in 1816 he was called upon to assist in the suppression of the Pindaris, though by the treaty of Gwalior (1817) he promised his co-operation, his conduct was so equivocal that in 1818 he was forced to sign a fresh treaty by which he ceded Ajmere and other lands.

Daulat Rao died without issue in 1827, and his widow, Baiza Bai (d. 1862), adopted Mukut Rao, a boy of eleven belonging to a distant branch of the family, who succeeded as Jankoji Rao Sindhia. His rule was weak and, in 1843, he was succeeded by another boy, adopted by his widow, Tara Bai, under the name of Jayaji Rao Sindhia. The growth of turbulence and misrule now induced Lord Ellenborough to interpose, and a British force under Sir Hugh Gough advanced upon Gwalior (December 1843).

The Mahratta troops were defeated simultaneously at Maharajpur and Punniar (December 29), with the result that the Gwalior Government signed a treaty ceding territory with revenue sufficient for the maintenance of a contingent force to be stationed at the capital. In 1857 the Gwalior contingent joined the mutineers; but the maharaja himself remained loyal to the British, and fled from his capital until the place was retaken and his authority restored by Sir Hugh Rose (Lord Strathnairn) on June 19, 1858. He was rewarded with the districts of Neemuch and Amjhera, but Gwalior fort was occupied by British troops and was only restored to his son in 1886 by Lord Dufferin. Jayaji Rao, who died in 1886, did much for the development of his state. He was created a G.C.S.I. in 1861, and subsequently became a counsellor of the empress, a G.C.B. and C.I.E.

His son, the maharaja, Madhava Rao Sindhia, G.C.S.I., was born in 1877. During his minority the state was administered for eight years by a council of regency. He was entrusted with ruling powers in 1894. The present ruler is H. H. Maharajah George Jivaji Rao Scindis Alijah Bahadur, born in 1916, who succeeded in 1925.

GWATKIN, HENRY MELVILL (1844–1916), English theological scholar, was born at Barrow-on-Soar, Leicestershire, on July 30, 1844, and was educated at Shrewsbury and St. John's College, Cambridge. In 1868 he became a fellow of St. John's, and in 1874 theological lecturer. He succeeded Creighton as Dixie professor of ecclesiastical history at Cambridge (1891). He died at Cambridge on Nov. 14, 1916.

His chief works were *Studies of Arianism* (1882); *The Knowledge of God* (1906, the published version of his Gifford lectures); and *Early Church History* (1909).

GWEEDORE, a tourist resort of Co. Donegal, Ireland. The river Clady affords salmon and trout fishing. To the east is Mt. Errigal (2,466 feet).

GWILT, JOSEPH (1784–1863), English architect and writer on architecture, was born at Southwark on Jan. 11, 1784, and died at Henley-on-Thames on Sept. 14, 1863. His most valuable work is his *Encyclopaedia of Architecture* (1842). He also wrote on philology and music. His principal buildings were Markree castle, near Sligo, Ireland, and St. Thomas's church at Charlton, Kent.

See Sebastian Gwilt, "Memoir of Joseph Gwilt," *R.I.B.A. Journal*, Feb. 15, 1864.

GWINNETT, BUTTON (c. 1735–1777), American merchant, patriot and signer of the Declaration of Independence, was born in Gloucester, England, probably in 1735, and removed to the Colony of Georgia in America sometime before 1765. On Feb. 2, 1776, he was elected a delegate from that colony to the Continental Congress, and as such signed the Declaration of Independence. His name is known to-day chiefly because his autographs are of extreme rarity, and collectors of the signers have forced their value to a high figure. Returning to Georgia he was a member of the convention to frame a new constitution for the State and speaker of the assembly. He was mortally wounded in a duel with Gen. Lachlan McIntosh, and died at his home on St. Catherine's island on May 19, 1777.

See C. F. Jenkins, *Button Gwinnett* (1926).

GWYN, NELL (ELEANOR) (1651–1687), English actress, and mistress of Charles II., was born on Feb. 2, 1651, probably in an alley off Drury Lane, London, although Hereford also claims to have been her birthplace. Her father, Thomas Gwyn, appears to have been a broken-down soldier of a family of Welsh origin; her mother lived for some time with her daughter, and was drowned in 1679, apparently when intoxicated, in a pond at Chelsea. Nell Gwyn, who sold oranges in the precincts of Drury Lane Theatre, became an actress at the age of 15, through the influence of the actor Charles Hart and of Robert Duncan or Dungan, an officer of the guards who had interest with the management. Her first recorded appearance on the stage was in 1665 as Cydaria, Montezuma's daughter, in Dryden's *Indian Emperor*, a serious part ill-suited to her. In the following year she was Lady Wealthy in James Howard's comedy *The English Monsieur*. Pepys was delighted with the playing of "pretty, witty Nell," but

when he saw her as Florimel in Dryden's *Secret Love, or the Maiden Queen*, he wrote "so great a performance of a comical part was never, I believe, in the world before" and, "so done by Nell her merry part as cannot be better done in nature" (*Diary*, March 25, 1667). Her success brought her other leading rôles—Bellario, in Beaumont and Fletcher's *Philaster*; Flora, in Rhodes's *Flora's Vagaries*; Samira, in Sir Robert Howard's *Surprisa!*; and she remained a member of the Drury Lane company until 1669, playing continuously save for a brief absence in the summer of 1667 when she lived at Epsom as the mistress of Lord Buckhurst, afterwards 6th earl of Dorset (*q.v.*). Her last appearance was as Almahide to the Almanzor of Hart, in Dryden's *The Conquest of Granada* (1670), the production of which had been postponed some months for her return to the stage after the birth of her first son by the king. As an actress Nell Gwyn was largely indebted to Dryden, who seems to have made a special study of her airy, irresponsible personality, and who kept her supplied with parts which suited her. She excelled in the delivery of the *risqué* prologues and epilogues which were the fashion.

It was, however, as the mistress of Charles II. that she endeared herself to the public. Partly, no doubt, her popularity was due to the disgust inspired by her rival, Louise de Kéroualle, duchess of Portsmouth, and to the fact that, while the Frenchwoman was a Catholic, she was a Protestant. But very largely it was the result of exactly those personal qualities that appealed to the monarch himself. She was *piquante* rather than pretty, short of stature, and her chief beauty was her reddish-brown hair. She was illiterate, and with difficulty scrawled an awkward E. G. at the bottom of her letters, written for her by others. But her frank recklessness, her generosity, her invariable good temper, her ready wit, her infectious high spirits and amazing indiscretions appealed irresistibly to a generation which welcomed in her the living antithesis of Puritanism. "A true child of the London streets," she never pretended to be superior to what she was, nor to interfere in matters outside the special sphere assigned her; she made no ministers, she appointed to no bishoprics, and for the high issues of international politics she had no concern. She never forgot her old friends, and, as far as is known, remained faithful to her royal lover from the beginning of their intimacy to his death, and, after his death, to his memory.

Of her two sons by the king, the elder was created Baron Hedington and earl of Burford and subsequently duke of St. Albans; the younger, James, Lord Beauclerk, died in 1680, while still a boy. The king's death-bed request to his brother, "Let not poor Nelly starve," was faithfully carried out by James II., who paid her debts from the Secret Service fund, provided her with other moneys, and settled on her an estate with reversion to the duke of St. Albans. She died in November 1687, and was buried on the 17th, according to her own request, in the church of St. Martin-in-the-Fields, her funeral sermon being preached by the vicar, Thomas Tenison, afterwards archbishop of Canterbury, who said "much to her praise." Tradition credits the foundation of Chelsea Hospital to her influence over the king.

See Peter Cunningham, *The Story of Nell Gwyn*, edited by Gordon Goodwin (1903); A. I. Dasent, *Nell Gwynne* (1924).

GWYNIAD, a species of the Salmonid genus *Coregonus*, inhabiting Bala lake in Wales, nearly identical with the powan of Loch Lomond and the schelly of Ullswater and Haweswater. The snout is truncated and the lower jaw included, as in related species from Scandinavia and Central Europe. (See WHITEFISH, SALMON AND SALMONIDAE.)

GYANTSE, one of the large towns of Tibet. It lies south-east of Shigatse, 130 m. from the Indian frontier and 145 m. from Lhasa. Its central position at the junction of the roads from India and Bhutan with those from Ladakh and Central Asia leading to Lhasa makes it a considerable distributing trade centre. Its market is the third largest in Tibet, coming after Lhasa and Shigatse, and is especially celebrated for its woollen cloth and carpet manufactures. Here caravans come from Ladakh, Nepal and upper Tibet, bringing gold, borax, salt, wool, musk and furs, to exchange for tea, tobacco, sugar, cotton goods, broadcloth and hardware. In the British expedition of 1904 Gyantse was one of

the first towns occupied, and by the treaty of the same year a British trade agent is stationed here.

GYGES, founder of the third or Mermnad dynasty of Lydian kings, reigned 687–652 B.C. according to H. Gelzer, 690–657 B.C. according to H. Winckler. As a youth, he was sent by the Lydian king Sadyattes to fetch TUDO, the daughter of Arnossus of Mysia, whom the Lydian king wished to make his queen. On the way Gyges fell in love with TUDO, and to escape punishment, assassinated Sadyattes and seized the throne. The civil war which ensued was finally ended by an appeal to the oracle of Delphi and the confirmation of the right of Gyges to the crown by the Delphian god. Further to secure his title he married TUDO. Under him the Troad was conquered, Colophon captured from the Greeks, Smyrna besieged and alliances entered into with Ephesus and Miletus. The Cimmerii, who had ravaged Asia Minor, were beaten back, and an embassy was sent to Assurbanipal at Nineveh (*c.* 650 B.C.) in the hope of obtaining his help against the barbarians. The Assyrians, however, were otherwise engaged, and Gyges turned to Egypt, sending troops to assist Psammetichus in shaking off the Assyrian yoke (660 B.C.). A few years later he fell in battle against the Cimmerii, and was succeeded by his son Ardys.

See C. Müller, *Fragmenta historiarum Graecorum*, iii.; R. Schubert, *Geschichte der Könige von Lydien* (1884); M. G. Radet, *La Lydie et le monde grec au temps de Mermnades* (1892–93); H. Gelzer, "Das Zeitalter des Gyges" (*Rhein. Mus.*, 1875); H. Winckler, *Altorientalische Forschungen*, i. (1893).

GYLIPPUS, a Spartan general of the 5th century B.C.; he was the son of Cleandridas, who had been expelled from Sparta for accepting Athenian bribes (446 B.C.) and had settled at Thurii. When Alcibiades urged the Spartans to send a general to take charge of the defence of Syracuse, Gylippus was appointed, and his arrival was undoubtedly the turning point of the struggle (414–413). When he arrived the Syracusans were on the point of negotiating for a surrender, but Gylippus at once took vigorous measures. His first move was to block the completion of the Athenians' encircling wall. Later he organized assistance among the other Sicilian cities, and was responsible for the decisive step of attacking the Athenian fleet in the harbour. Persisting in this policy in spite of an early reverse, he turned defence into attack. According to Thucydides, who is probably right, he wished to spare the Athenian commanders when they were captured, in order to take them to Sparta. Later, entrusted with a large sum by Lysander to deliver to the ephors, he embezzled it, and went into exile when discovered.

See Thucydides, vi. 93, 104, vii.; Plutarch, *Nicias*, 19, 21, 27, 28, *Lysander*, 16, 17; Diodorus, xiii. 7, 8, 28–32; Polyaeus, i. 39, 42. See SYRACUSE (for the siege operations), commentaries on Thucydides and the Greek histories.

GYLLEMBOURG-EHRENSVÄRD, THOMASINE CHRISTINE, BARONESS (1773–1856), Danish author, was born on Nov. 9, 1773, at Copenhagen. Her maiden name was Buntzen. Before she was 17 she married the famous writer P. A. Heiberg. Their son was afterwards illustrious as the poet and critic J. L. Heiberg. In 1800 her husband was exiled, and she obtained a divorce, marrying in Dec. 1801 the Swedish Baron K. F. Ehrens-värd, himself a political fugitive. Her second husband, who presently adopted the name of Gyllembourg, died in 1815. In 1822 she followed her son to Kiel, where he was professor, returning with him to Copenhagen in 1825. Her most famous work is *En Hverdags historie* (*An Everyday Story*). On July 2, 1856, she died in her son's house at Copenhagen. For English readers no closer analogy can be found than between her and Mrs. Gaskell, and *Cranford* might well have been written by the witty Danish authoress.

See J. L. Heiberg, *Peter Andreas Heiberg og Thomasine Gyllembourg* (1882), and L. Kornelius-Hybel, *Nogle Bemaerkninger om P. A. Heiberg og Fru Gyllembourg* (1883).

GYLLENSTJERNA, JOHAN, COUNT (1635–1680), Swedish statesman, began his political career at the diet which assembled on the death of Charles X. (1660). An aristocrat by birth and inclination, he was nevertheless a true patriot and demanded the greatest sacrifices from his own order in the national interests. He laboured zealously for the recovery of the crown lands, and in

the Upper House he was the spokesman of the gentry against the magnates, whose inordinate privileges he would have curtailed or abolished. His adversaries vainly endeavoured to gain him by favour, for as court-marshal and senator he was still more hostile to the patricians who followed the policy of Magnus de la Gardie. Thus he opposed the French alliance which de la Gardie carried through in 1672, and consistently advocated economy in domestic and neutrality in foreign affairs. On the outbreak of the war in 1675 he loyally supported the young Charles XI., whose indispensable counsellor he became. Indeed, it may be said, that the political principles which he instilled into the youthful monarch were faithfully followed by Charles during the whole of his reign. In 1679 Gyllenstjerna was appointed the Swedish plenipotentiary at the peace congress of Lund. The alliance which he then concluded with Denmark bound the two northern realms together in a common foreign policy, and he sought besides to facilitate their harmonious co-operation by every means in his power. In 1680, after bringing home Charles XI.'s Danish bride from Copenhagen, he was appointed governor-general of Scania (Skåne), but died a few weeks later.

See M. Höjer, *Öfversigt af Sveriges yttre politik under åren 1676-1680* (Upsala, 1875). (R. N. B.; X.)

GYMKHANA, a display of miscellaneous sports, originally at the military stations of India. The word would seem to be a colloquial remodelling of the Hindustani *gend-khana*, ball-house or racket-court, by substituting for *gend* the first syllable of the word "gymnastics." The first meetings consisted of horse and pony races at catch weights. To these were soon added a second variety, originally called the *pāgōl* (funny races), the one generally known outside India, which consisted of miscellaneous races and competitions of all kinds, some serious and some amusing, on horseback, on foot and on bicycles.

GYMNASTICS AND GYMNASIUM, terms signifying respectively a system of physical exercises practised either for recreation or for the purposes of promoting the health and development of the body, and the building where such exercises are carried on.

The Gymnasium in Greece.—The gymnasium of the Greeks was originally the school where competitors in the public games received their training, and was so named from the circumstances that these competitors exercised naked (*γυμνός*). The gymnasium was a public institution as distinguished from the palaestra, which was a private school where boys were trained in physical exercises, though the term palaestra is also often used for the part of a gymnasium specially devoted to wrestling and boxing. The athletic contests for which the gymnasium supplied the means of training and practice formed part of the social life of the Greeks from the very earliest times; and accordingly special buildings were provided by the State and their management entrusted to public officials. The regulation of the gymnasium at Athens is attributed by Pausanias (i. 39.3) to Theseus. Solon made several laws on the subject; but according to Galen it was reduced to a system in the time of Cleisthenes. Ten *gymnasiarchs*, one from each tribe, were appointed annually. These performed in rotation the duties of their office, which were to maintain and pay the persons who were training for public contests, to conduct the games at the great Athenian festivals, to exercise general supervision over the morals of the youths, and to adorn and keep up the gymnasium. This office was one of the ordinary *leitourgiai* (public services), and great expense was entailed on the holders. Under them were ten *sophronistae*, whose duty was to watch the conduct of the youths at all times, and especially to be present at all their games. The practical teaching and selection of the suitable exercises for each youth were in the hands of the *paedotribae* and *gymnastae*, the latter of whom also superintended the effect on the constitution of the pupils, and prescribed for them when they were unwell. The *aleiptae* oiled and rubbed dust on the bodies of the youths, acted as surgeons, and administered the drugs prescribed. According to Galen there was also a teacher of the various games of ball. The gymnasia built to suit these various purposes were large buildings, which contained not merely places for each kind of exercise, but also a

stadium, baths, covered porticos for practice in bad weather, and outer porticos where the philosophers and men of letters read public lectures and held disputations.

The gymnasium of the Greeks did not long remain an institution exclusively devoted to athletic exercises. It soon began to be applied to other uses even more important. The development arose naturally through the recognition by the Greeks of the important place in education occupied by physical culture, and of the relation between exercise and health. The gymnasium accordingly became connected with education on the one hand and with medicine on the other. Due training of the body and maintenance of the health and strength of children were the chief part of earlier Greek education. Except the time devoted to letters and music, the education of boys was conducted in the gymnasia, where provision was made, as already mentioned, for their moral as well as their physical training. As they grew older, conversation and social intercourse took the place of the more systematic discipline. Philosophers and sophists assembled to talk and to lecture in the gymnasia, which thus became places of general resort for the purpose of all less systematic intellectual pursuits, as well as for physical exercises. In Athens there were three great public gymnasia—Academy, Lyceum and Cynosarges—each of which was consecrated to a special deity with whose statue it was adorned; and each was rendered famous by association with a celebrated school of philosophy. Plato's teaching in the academy has given immortality to that gymnasium; Aristotle conferred lustre on the lyceum; and the cynosarges was the resort of the cynics. Plato, when treating of education, devotes much consideration to gymnastics (see especially *Rep.* iii. and various parts of *Laws*); and according to Plato it was the sophist Prodicus who first pointed out the connection between gymnastics and health. Having found such exercises beneficial to his own weak health, he formulated a method which was adopted generally, and which was improved by Hippocrates. Galen lays the greatest stress on the proper use of gymnastics, and throughout ancient medical writers we find that special exercises are prescribed as the cure for special diseases.

The Gymnasium in Rome.—The Greek institution of the gymnasium never became popular with the Romans, who regarded the training of boys in gymnastics with contempt as conducive to idleness and immorality, and of little use from a military point of view; though at Sparta gymnastic training had been chiefly valued as encouraging warlike tastes and promoting the bodily strength needed for the use of weapons and the endurance of hardship. Among the Romans of the republic, the games in the Campus Martius, the duties of camp life, and the enforced marches and other hardships of actual warfare, served to take the place of the gymnastic exercise required by the Greeks. The first public gymnasium at Rome was built by Nero and another by Commodus. In the middle ages, though jousts and feats of horsemanship and field sports of various kinds were popular, the more systematic training of the body which the Greeks had associated with the gymnasium fell into neglect, while the therapeutic value of special exercises as understood by Hippocrates and Galen appears to have been lost sight of. Rousseau, in his *Emile*, was the first in modern times to call attention to the injurious consequences of such indifference, and he insisted on the importance of physical culture as an essential part of education. It was probably due in some measure to his influence that F. L. Jahn and his followers in Germany, encouraged by the Prussian minister Stein, established the *Turnplätze*, or gymnastic schools, which played an important part during the War of Liberation, and in the political agitations which followed the establishment of the German confederation by the Congress of Vienna. The educational reformers Pestalozzi and Froebel emphasized the need for systematic physical training in any complete scheme of education.

Modern Developments.—The later development of the classical gymnasium (when it had become the school of intellectual culture rather than of exclusively physical exercise), and not the original idea, has been perpetuated in the modern use of the word in Germany, where the name "gymnasium" is given to

the highest grade of secondary school, and the association of the word with athleticism has been entirely abandoned. On the other hand, in England, France and elsewhere in Europe, as well as in America, the history of the word has been precisely the reverse; the connection of the gymnasium with philosophy and mental culture has been dropped, and it indicates a building exclusively intended for the practice of physical exercises. But whereas the Greeks received training in the gymnasium for contests which are now designated as *athletic sports* (*q.v.*), gymnastics in the modern sense is a term restricted to such exercises as are usually practised indoors, with or without the aid of mechanical appliances, as distinguished from sports or games practised in the open air.

It was not until near the end of the 19th century that gymnastics were recognized in England as anything more than a recreation; their value as a specifically therapeutic agent, or as an article in the curriculum of elementary schools, was not realized. More recently, however, educationists have urged with increasing insistence the need for systematic physical training, and their views received greater attention when evidence of deterioration in the physique of the people began to accumulate. During the first decade of the 20th century more than one commission reported to parliament in England in favour of more systematic and general physical training being encouraged or even made compulsory by public authority. Voluntary associations were formed for encouraging such training and providing facilities for it. Gymnastics had already for several years been an essential part of the training of army recruits with exceedingly beneficial results, and gymnasia had been established at Aldershot and other military centres. Physical exercises, although not compulsory, obtained a permanent place in the code for elementary schools in Great Britain; and much care has been taken to provide a syllabus of exercises adapted for the improvement of the physique of the children. These exercises are partly gymnastic and partly of the nature of drill; they do not in most cases require the use of appliances, and are on that account known as "free movements," which numbers of children go through together, accompanied whenever possible by music. On the other hand, at the larger public schools and universities there are elaborate gymnasia equipped with a great variety of apparatus, the skilful use of which demands assiduous practice; and this is encouraged by annual contests between teams of gymnasts representing rival institutions.

Gymnastic Apparatus.—The appliances vary to some extent in different gymnasia, some of the more complicated requiring a greater amount of space and involving a larger cost than is often practicable. But where these considerations are negligible, substantial uniformity is to be found in the equipment of gymnasia not designed for specifically medical purposes. The simplest, and in many respects the most generally useful, of all gymnastic apparatus is the dumb-bell. It was in use in England as early as the time of Elizabeth, and it has the advantage that it admits of being exactly proportioned to the individual strength of each learner, and can be adjusted in weight as his strength increases. The exercises that may be performed with the dumb-bell, combined with a few simple drill-like movements, give employment to all parts of the body and to both sides equally. Dumb-bell exercises, therefore, when arranged judiciously and with knowledge, are admirably suited for developing the physique, and are extensively employed in schools both for boys and girls. The bar-bell is merely a two-handed dumb-bell, and its use is similar in principle. The Indian club is also in use in most gymnasia; but the risk of overstraining the body by its unskilful handling makes it less generally popular than the dumb-bell. All these appliances may be, and often are, used either in ordinary school-rooms or elsewhere outside the gymnasium. The usual fixed sorts of apparatus, the presence of which (or of some of them) in a building may be said to constitute it a gymnasium, are the following: a leaping-rope; a leaping-pole; a vaulting-horse; a horizontal bar, so mounted between two upright posts that its height from the ground may be adjusted as desired; parallel bars, used for exercises to develop the muscles of the trunk and arms; the

trapeze consisting of a horizontal bar suspended by ropes; the bridge ladder; the plank; the inclined plane; swinging rings; the prepared wall; the horizontal beam.

Before the end of the 19th century the therapeutic value of gymnastics was fully realized by the medical profession; and a number of medical or surgical gymnasia came into existence, provided with specially devised apparatus for the treatment of different physical defects or weaknesses. The exercises practised in them are arranged upon scientific principles based on anatomical and physiological knowledge; and these principles have spread thence to influence largely the practice of gymnastics in schools and in the army. A French medical writer enumerates seven distinct groups of maladies, each including a number of different complaints, for which gymnastic exercises are a recognized form of treatment; and there are many malformations of the human body, formerly believed to be incurable, which are capable of being improved if not entirely corrected by regular gymnastic exercises practised under medical direction.

Cure of Physical Defects.—The value of gymnastics both for curing defects, and still more for promoting health and the development of normal physique, is recognized even more clearly on the continent of Europe than in Great Britain. In Germany, the Government not only controls the practice of gymnastics but makes it compulsory for every child and adult to undergo a prescribed amount of such physical training. In France, also, physical training by gymnastics is under State control; in Sweden, Denmark, Switzerland, Italy, Russia, systems more or less distinct enjoy a wide popularity; and in Finland gymnastics are practised on lines that exhibit national peculiarities. The Finns introduce an exceptional degree of variety into their exercises as well as into the appliances devised to assist them; women are scarcely less expert than men in the performance of them; and the enthusiasm with which the system is supported produces the most beneficial results in the physique of the people. International gymnastic contests have become a feature of the revived Olympic games (*see* *ATHLETIC SPORTS*), and in those held at Athens in 1906 a team of Danish ladies took part in the competition and proved by their skilful performance that gymnastics may be practised with as much success by women as by men.

Influence of the Olympic Games.—The undoubted influence of the revived Olympic games upon the modern development of athletic sports and exercises has not greatly affected gymnastics, perhaps because of the already high state of efficiency reached prior to the revival. The International Gymnastic Federation, which has but one affiliated nation outside Europe, *i.e.*, the United States, was founded in 1881, and 20th century efforts have tended rather to consolidation and perfection than to extension and progress. One important feature was the foundation, in 1923, of an international federation for the promotion of the educative, instead of the executive, branch of the art. Both federations have their British affiliations, that to the *Fédération Internationale de Gymnastique* being the Amateur Gymnastic Association and that to the *Fédération Internationale de Gymnastique Educative* being the Ling Association.

The enormous development of athletic sports throughout most of the European countries has not caused gymnastics to suffer; the great festivals at Nuremberg, Leipzig, Frankfurt, and in Sweden, France and Switzerland continue to attract thousands of gymnasts. Perhaps the name which should most laudably be connected with this development is that of Gen. Sir Viktor Balck, of Stockholm, who was awarded the G.C.B. for the value of his suggestions in the training of British soldiers and sailors. His system of Swedish gymnastics has proved its efficacy and success all over the world and has largely contributed to the high national standard of health enjoyed by the Scandinavian races. On the continent of Europe the gymnastic movement is national; in Great Britain, and to a lesser extent in the United States (*q.v.*), interest in gymnastics is individual. The repetitive character, the absence of the competitive spirit, perhaps also the collective discipline so necessary, appear to have too little in common with the Anglo-Saxon character for gymnastics ever to arouse the enthusiasm which prevails in the European countries. The inclusion

of gymnastic competitions at the Olympic games has not appreciably affected the situation. The most practical form of exercises taught in national gymnasia is undoubtedly to be found in Japan, where the ancient art or science of defence (and offence) known as ju-jitsu has proved of the greatest service to the police and others, and has gradually been recognized in other parts of the world as indispensable to complete physical equipment. (See **ATHLETICS; OLYMPIC GAMES.**)

The chief work on the ancient gymnastics is Krause, *Gymnastik und Agonistik der Hellenen* (1841). Of more recent works mention may be made of Becker-Göll, *Charicles*, ii.; Brugsma, *Gymnastorium apud Graecos descriptio* (1855); Petersen, *Das Gymnasium der Griechen* (1858); A. S. Wilkins, *National Education in Greece* (1873); L. Grasberger, *Erziehung und Unterricht in klassischen Altertum* (1881); Jäger, *Gymnastik der Hellenen* (1881); J. P. Mahaffy, *Old Greek Education* (1883); E. Paz, *Histoire de la gymnastique* (1886); Wickenhagen, *Antike und moderne Gymnastik* (1891). See also N. Laisné, *Gymnastique pratique* (1879); Collineau, *La Gymnastique* (1884); L'Hygiène à l'École (1889); P. de Coubertin, *La Gymnastique utilitaire* (1905); H. Nissen, *Rational Home Gymnastics* (Boston, 1903).

The United States.—Gymnastics were first taught in America by two pupils of Jahn, in 1825, Charles Follen and Charles Beck, who copied closely the equipment and methods of the German Turnplatz. They were soon diverted to other pursuits, and the movement instituted by them languished, until, in 1860, Dio Lewis, with his "New Gymnastics," demonstrated light and free exercises with barbells, wooden dumbbells, bean bags and rings to admiring audiences. He emphasized the value of light exercise as opposed to the heavy gymnastics of the early German pioneers, and founded a short-lived institute for training teachers; but his interest soon turned to other fields, and in 10 years the life of the movement was almost extinct.

The great emigration from Germany about 1848 brought with it the Turners and in every German community a *Turngemeinde* was founded. Their gymnastic societies became centres of propaganda for physical education, especially for the schools, and the Normal school now at Indianapolis was one of the first to train teachers in the tradition of German gymnastics for the public schools. About 1870 the Young Men's Christian Association began to consider the body as well as the soul, and in 1875 they founded what is now the International Y.M.C.A. training college at Springfield, Mass., for training teachers to carry on the work, not only in the Y.M.C.A. of America and abroad but also in schools and colleges. In 1879 the Hemenway gymnasium was opened at Harvard, equipped with Dudley A. Sargent's apparatus, by which the bars and trapezes could be adapted to the weakest as well as the strongest by means of pulley weights. Class-work was replaced by individual advice.

The Swedish system was introduced to America by Baron Nils Posse, and the Boston Normal School of Gymnastics was founded about 1889. Other schools followed, but this became the main source of supply for teachers of Swedish gymnastics. For the next 20 years the relative merits of Swedish and the German gymnastics formed a favourite field of debate at the Annual Conventions of the American Physical Education Association.

About the beginning of the 20th century college after college began to require gymnastics as part of the regular course, and a change came over the equipment and courses of instruction. But the revival of athletic sports modified the programme and made it approach much more closely to the traditional Greek ideal of exercise. With the recognition of physical education as part of the curriculum it has become possible to allow a wide latitude in the form of exercise taken by all students who are physically sound, and the rudiments of such exercises as boxing, wrestling and team games can be taught to classes like gymnastic drill. The more proficient pass on to more strenuous personal competition, the others taking their gymnastic training in movements that they find more interesting than the more artificial drill which characterizes the German and Swedish gymnastics. The defective student is provided for by individual corrective exercises for his special needs.

Gymnasiums, swimming pools and playgrounds have been established in the crowded parts of the city, with expert instructors.

Gymnastic classes and organized games form an important part of the activities of these recreation centres.

The most potent influence in extending physical education has been the passing of State laws making physical training part of the regular curriculum in the public schools. This occurred in response to the amount of physical inefficiency revealed by recruits during the World War. New York began this movement in 1916 and California in 1917, and similar laws have been passed (1928) in 35 States. This legislation has brought to a focus the question of adequate training for teachers to carry out the provisions of the act. The Normal schools first in the field were mostly proprietary, but they are becoming affiliated with colleges which have degree-granting power. State Normal schools are conducting two- or three-year courses and many colleges and universities are giving four-year courses in physical training. These courses are rapidly becoming standardized and include instruction in anatomy, physiology and psychology, and hygiene, practice in gymnastics, dancing and athletics and teaching, together with the literary and other cultural subjects necessary to put the teachers of physical education on the same educational level as the others on the staff.

GYMNOSOPHISTS, the name given by the Greeks to certain ancient Hindu philosophers who pursued asceticism to the point of regarding food and clothing as detrimental to purity of thought (Lat. *gymnosophistae*, from Gr. γυμνός, σοφιστής "naked philosophers"). From the fact that they often lived as hermits in forests, the Greeks also called them *Hyllobioi* (cf. the *Vāna-prasthās* in Sanskrit writings). Diogenes Laërtius (ix. 61 and 63) refers to them, and asserts that Pyrrho of Elis, the founder of pure scepticism, came under their influence, and on his return to Elis imitated their habits of life, to what extent does not appear. Strabo (xv. 711, 714) divides them into Brahmins and Sarmans (or Shamans). See **JAINS**.

GYMNOSPERMS. All living seed-bearing plants are divided into two groups, the Gymnosperms and the Angiosperms (*q.v.*), and it is certain that these two groups are only distantly related, if indeed they are directly related at all. The primary distinction between the two lies in the fact that, at the time of pollination, the ovule (or rudimentary seed) is freely exposed, and the pollen deposited on it (or very rarely near it) in Gymnosperms (indicating plants with naked seeds), but in Angiosperms is wholly enclosed in an ovary, on a specialized part of which (the stigma) the pollen is deposited. There are other important differences, both in anatomy and in reproductive structures. In particular the prothallus (or embryo-sac) is a much larger and more massive structure in Gymnosperms than in Angiosperms, and (with the exception of two tropical genera) the female organ characteristic of the group is a large archegonium similar in structure and development to the much smaller archegonium found in all mosses and ferns and their allies, but of which no trace is found in Angiosperms. As regards anatomical features no companion cells are found in the phloem of Gymnosperms, nor, except in one division, are true vessels met with in the wood.

Although no other living plants besides Gymnosperms and true flowering plants (Angiosperms) have seeds, yet fossil representatives of the club mosses are known which possess such structures. These plants are, however, so clearly and definitely related to the club mosses (Lycopodiaceae) on other grounds, and not to the Gymnosperms, that it is not necessary to discuss them further. (See **PTERIDOPHYTES** and **PALAEOBOTANY: Palaeozoic.**)

The Gymnosperms are of special interest on account of their great antiquity, which far exceeds that of the true flowering plants, and as comprising different types which carry us back to the Palaeozoic era and to the forests of the coal period. It is not surprising in a group of such antiquity to find that some divisions are wholly extinct. There are, in all, seven of these divisions of which three are extinct, one is represented by a single living species, the maidenhair tree, common enough in cultivation but

almost extinct in the wild state, and three are flourishing living divisions, though only one of these, the Coniferales (pines, cedars, larches, firs, yews, etc.) is a really large and important division of existing plants.

The seven divisions of the Gymnosperms show many indications of fairly close relationship and this appears to indicate that the whole group had a common origin, though this view is not by any means certain and is not universally accepted. If we accept the view that all the Gymnosperms had a common origin then there can scarcely be any doubt that the group from which they were evolved was the Filicales or true ferns, the resemblance between the latter and the most primitive division of Gymnosperms, the Pteridospermae or Cycadofilicales, being very striking. (See PALAEOBOTANY: Palaeozoic.)

Although the reproductive structures of the Gymnosperms are often described as "flowers," it seems better to avoid this term, as implying a resemblance, which scarcely exists, to the "flowers" of Angiosperms. The term "cone" will, therefore, be used throughout this article in preference to "flower," except in the case of the highest division, the Gnetales, where the resemblance to Angiosperms is more obvious.

The seven divisions of Gymnosperms are as follows:—

I. PTERIDOSPERMAE or CYCADOFILICALES. Wholly extinct. (See PALAEOBOTANY: Palaeozoic.)

II. CYCADALES. A living division, also represented in the Mesozoic.

III. BENNETTITALES. Wholly extinct. (See PALAEOBOTANY: Mesozoic.)

IV. GINKGOALES. Mostly extinct, with a single living species.

V. CORDAITALES. Wholly extinct. (See PALAEOBOTANY: Palaeozoic.)

VI. CONIFERALES. By far the largest and most important division of living Gymnosperms.

VII. GNETALES. Includes only three genera, with no known fossil representatives, but with some characters very suggestive of Angiosperms.

No further reference will be made here to the extinct divisions of Gymnosperms.

The living Gymnosperms agree in the following characters: Woody plants. Cones unisexual, monoecious or dioecious. Perianth not present except in Gnetales. Ovules naked, usually borne on

leaf-like structures. The single megaspore enclosed in the nucellus becomes filled with tissue (prothallus) before fertilization (partially only or not at all in *Gnetum*); the microspore develops at least four nuclei (usually four to six) of which two are the male cells, very large and actively motile in Cycads and *Ginkgo*, much smaller and only motile in so far as they are passively carried by the pollen tube, in Coniferales and Gnetales.

Some account will now be given in turn of each of the four living divisions.

CYCADALES

General.—This division includes nine genera and over 80 species. It consists of plants with

tuberous or columnar stems, seldom branched, often clothed with an armour of petiole bases as in the stems of ferns, and terminating in a crown of large pinnate leaves (bi-pinnate in one genus). The plants are dioecious, with the cones always compact, with numerous sporophylls spirally arranged on an axis, except in female plants of *Cycas*, which bear on the main stem a loose rosette of leaf-like sporophylls each bearing from 2 to 6 or 8 ovules.

The cycads are practically confined to tropical and subtropical regions and are fairly equally divided both between northern and

southern and between eastern and western hemispheres. *Zamia* includes over 30 species which extend from Southern Florida to Chili. *Cycas* has only about 16 species, but they range from Japan to Australia. *Macrozamia* with 14 species is confined to Australia, while *Encephalartos* with 12 species is wholly South African. No other genus has more than three species. *Dioon* and *Ceratozamia* are both restricted to South Mexico, and *Bowenia* to Australia,

FIG. 2.—BOWENIA SPECTABILIS FROND

FIG. 3.—MACROZAMIA HETEROMERA

while *Microcycas* and *Stangeria* occur only in West Cuba and South Africa respectively.

Externally some of the larger cycads closely resemble palms, others having an equally close resemblance to tree ferns, while so closely do the smaller species approximate to ferns in appearance (when not in cone) that *Stangeria* was actually first described (by Kunze in 1835) as a species of the fern *Lomaria*.

Cycads are characteristically very long lived and slow growing and certainly reach an age of upwards of a thousand years, probably much more.

The armour of dead leaf bases found on the old stem (fig. 1) is more particularly characteristic of the columnar forms, and is not found in *Bowenia* and *Stangeria*.

In the tuberous forms the stem is usually more or less subterranean, but may be very massive, like a gigantic carrot. The leaves of *Cycas* consist of a long rachis bearing numerous linear leaflets, each with a single midrib and no other veins. When young these leaflets are coiled up like the leaves of a fern. In most other cycads the leaves are similar except that the leaflets contain a number of parallel veins, e.g.

Dioon and *Encephalartos*. *Stangeria* has only a few leaflets on the rachis and each is traversed by a midrib from which simple or forked veins pass off at a wide angle. The leaves of *Bowenia* differ from those of other genera in being bi-pinnate (fig. 2). It is only in *Cycas* that the young leaflets are conspicuously coiled, the remaining genera showing little or no trace of this character. In *Macrozamia heteromera* the narrow pinnae are dichotomously branched almost to the base (fig. 3). In some forms, such as most of the species of *Encephalartos*, the margins of the leaflets are

FIG. 1.—ENCEPHALARTOS GHELELI LINCKII

spinous. In *Ceratozamia* the broad petiole base is characterized by the presence of two lateral spinous processes suggestive of stipules, and comparable with the stipules of Marattiaceous ferns.

Cones.—The "male" (or microsporangiate) cones of cycads (fig. 4) are very uniform in structure, and from one to a hundred may be produced in one season. Each consists of an axis bearing crowded, spirally disposed sporophylls, which are often wedge-shaped and angular, while in other cases they consist of a short, thick stalk terminating in a peltate expansion or prolonged upwards in the form of a triangular lamina (fig. 5). The crowded sporangia (pollen-sacs) are found on the lower side of the sporophyll and are often arranged in more or less definite groups (or "sori"). The sporangia break open when ripe by a slit radiating from the centre of the sorus. The sporangia are large, not unlike those of *Angiopteris* (a Marattiaceous fern) and their walls are several layers of cells in thickness. Each sporangium contains several oval spores which develop into pollen grains before they are set free. In this process each spore cuts off a small but persistent "prothallial cell," and immediately divides again to cut off an almost equally small "generative cell," the remaining nucleus, occupying the larger part of the spore cavity, being the "tube nucleus." In this 3-celled condition the pollen is shed.

The female plants bear cones which in most genera occur singly in the centre of the crown, but in *Encephalartos*, *Bowenia* and *Macrozamia* from two to several may be found. In some cases these female cones reach an enormous size, that of *Encephalartos Caffer* being up to a yard in length and weighing as much as 100 lb., while that of *Macrozamia Denisoni* may be as long, though its weight seldom exceeds 60 lb. The smallest cones are those of *Zamia*, that of *Zamia pygmaea* being sometimes less than 3 cm. in length. The sporophylls usually have some, often a close, resemblance to those of the male cone, and are clearly homologous with them.

The most primitive type is evidently *Cycas*, in which the sporophylls are arranged round the apex like a crown of foliage leaves and are definitely leaf-like in form. In *C. revoluta* and *C. circinalis* each may produce several laterally attached ovules, but in *C. Normanbyana* the sporophylls are shorter and the ovules are reduced to two. In all other genera the cone is a much more definite and compact structure, but the sporophylls of *Dioon* and *Stangeria* terminate in a leaf-like up-turned process, and are clearly comparable with those of *Cycas*. In some of the remaining genera the sporophylls are shorter with thick peltate heads, and each bears two ovules on the lower surface (fig. 6). The young ovule consists of a spherical or ovoid rather massive nucellus, sur-

FROM LOTSY, "VORTRAGE ÜBER BOTANISCHE STAMMESGESCHICHTE" (FISCHER)
FIG. 6.—MEGASPOROPHYLLS OF CYCADS: A. CYCAS; B. DIOON; C. CERATOZAMIA

rounded by the integument. The small round opening at the apex of the integument is known as the micropyle.

Fertilization and Development.—The pollen is carried by the wind, or very rarely, perhaps, by small beetles or other insects, to the micropyle and lodges there. Meanwhile the tip of the nucellus projects into the base of the micropyle in the form of a tiny beak, at the exact tip of which a fine hole appears, becoming somewhat wider below. This narrow but relatively deep hole, the "pollen chamber," being exactly below the centre of the micropyle, the pollen grains pass into it (or, in some cases at least, are drawn

into it by the evaporation of a drop of liquid which oozes out from the micropyle at the time of pollination, as in conifers) and the tip of the pollen chamber, as well as the micropyle, closes and hardens, thus completely enclosing the pollen grains, of which from half a dozen to a dozen are usually found here. Later these develop pollen tubes as described below.

While these changes are going on, a large cell, the megaspore, makes its appearance in the central region of the nucellus, rapidly

FIG. 7.—SEMI-DIAGRAMMATIC LONGITUDINAL SECTION OF A PART OF CYCAD OVULE BEFORE FERTILIZATION

increases in size, and ultimately absorbs the greater part of the nucellus. Its nucleus divides repeatedly and cells are produced from the peripheral region inwards, which eventually fill the spore cavity with a homogeneous tissue, the prothallus. From one to ten separate superficial cells at the apex of the prothallus now increase in size. Each cuts off a small cell at the top, which divides to form the small two-celled neck of the archegonium, the lower cell enlarging rapidly and becoming the egg-cell, its nucleus cutting off another small nucleus (which soon disappears) just before fertilization (fig. 7). In *Microcycas* a very large number of archegonia (up to 200 exceptionally) are produced all over the prothallus.

During the development of the prothallus the pollen chamber has enlarged both downwards and outwards, and eventually forms a fairly large chamber open below to the archegonia, which themselves lie at the bottom of a shallow depression in the apex of the prothallus, the "archegonial chamber." Each pollen grain at once begins to put out a tube which grows laterally into the nucellus just below its outer surface. The apical part of the nucellus is almost the only part remaining by this time, and is known as the "nucellar cap." Close inspection of the outer surface of the nucellar cap reveals several dark lines radiating from the beak outwards for about 2 mm. and these mark the positions of the pollen tubes. The "tube nucleus" of the pollen grain passes into, and remains in, the pollen tube, while the pollen grain hangs suspended by its tube in the pollen chamber (fig. 7). The "generative cell" divides to form another small sterile cell, the "stalk cell," and a much larger cell the "body cell," which continues to enlarge (as does that part of the tube to which the grain is attached) and finally divides once more into two equal hemispherical cells, in each of which a single very large and actively motile spermatozoid is produced (fig. 8). (In *Microcycas* 8 to 10 body cells and 16 to 20 sperms are formed in each pollen tube.) In the course of the last division two small bodies known as "blepharoplasts" make their appearance just outside the nucleus, and after division is complete one of them remains in each spermatozoid where it

FIG. 8.—CYCAD POLLEN TUBE WITH SPERMS IN MOTHER CELLS

gradually gives rise to a spiral band which passes round and round the outside of each sperm while from the outside of the band innumerable fine hair-like cilia are produced which, by their active movements, enable the sperms to swim about, first in the two cells within which they are formed, then in the part of the pollen tube adjacent to the grain after the cell walls break down, and finally in the film of moisture covering the archegonial chamber, after the bursting of the pollen tube. At last one penetrates the neck cells of an archegonium and so finds its way into the egg cell, where the sperm nucleus slips from its ciliated sheath of protoplasm and swiftly passes down to fuse with the large egg nucleus.

It is noteworthy that cycad sperms are the largest known in either plants or animals, and the only ones big enough to be definitely seen under ordinary lighting conditions, and while still living, with the naked eye, the largest of them reaching a diameter of more than a quarter of a millimetre. It is no less remarkable that sperms had been observed repeatedly in every other great group of both plants and animals (excepting *Ginkgo*) many years before they were ever seen in cycads, although the discovery of motile sperms in Gymnosperms had been predicted nearly 50 years earlier by the great German botanist Hofmeister. They were actually seen for the first time in *Cycas* in 1896 by a Japanese botanist, S. Ikeno, and shortly afterwards in *Zamia* by H. J. Weber, and since that time they have been carefully studied in most of the other genera.

Following fertilization, the fusion nucleus divides repeatedly till from 250 to about 1,000 nuclei are scattered through the protoplasm of the archegonium. These nuclei tend to be more closely aggregated at the base, and cell walls first appear in this region, thus forming a tissue at the base of each fertilized archegonium. An ephemeral tissue may also form throughout the archegonium, as happens in most genera, subsequently breaking down to form a cavity, or the centre of the archegonium may become a large vacuole at an earlier stage, as in *Cycas*. In either case the structure thus formed constitutes the proembryo. A compact group of cells at the extreme base forms the actual embryo, and the cells immediately above these elongate very much and eventually form a very long coiled and tangled suspensor which carries the embryo deep into the prothallus where it grows to about three-quarters of the length of the latter and absorbs about one-quarter of its tissue.

The mature embryo consists of an axis (the hypocotyl) terminated, at the end next to the suspensor, by a rudimentary root (the radicle) enclosed in a hard covering, the coleorhiza, and bearing at the other end a pair of large seed leaves or cotyledons, often fused together at their tips, and enclosing between them a minute terminal bud, the plumule. The integument of the ovule has now become the testa of the seed and is differentiated into three layers, an outer, thick, fleshy and brightly coloured one, in the inner part of which several vascular strands run up from the base, a thin hard woody layer, and a very thin inner fleshy layer containing a second set of vascular strands.

Anatomy.—The anatomy of the cycads presents many features of interest. Only a brief reference to one or two of the most striking of these is possible here. The wood is rather soft and laxly arranged and occupies a relatively small part of the thickness of the stem, though the vascular cylinder very slowly increases in thickness in the same manner as in woody Dicotyledons. Sometimes, as in *Cycas*, there is a double ring of vascular strands. In connection with the leaves two strands often branch off from the central cylinder on the opposite side to a leaf, pass spirally round in the cortex in opposed directions and pass into the petiole of that leaf, where they break up into a larger number of strands. This arrangement of leaf trace strands is peculiar to cycads, and the strands themselves are often known as girdles. For further anatomical details reference may be made to *The Living Cycads* by C. J. Chamberlain.

Classification.—Something has already been said about the characteristic features of certain genera. It will, however, be convenient to conclude with a key to all the genera, and the usual classification of the Cycadales, as follows:—

Division CYCADALES. Only family Cycadaceae.

Tribe A. Female plant with separate leaf-like sporophylls on the main stem. Leaflet with a midrib only. Cycadeae. *Cycas*.

Tribe B. Sporophylls always in compact cones. Zamieae.

Sub-tribe I. Leaflet with midrib and lateral veins. Stangerieae. *Stangeria*.

Sub-tribe II. Leaflet with several parallel veins. Euzamieae.

a. Leaves bi-pinnate. *Bowenia*.

b. Leaves simply pinnate.

(i.) Megasporophylls (Carpels) with a terminal leafy part.

*Ovules on a cushion-like placenta. *Dioon*.

**Ovules sessile. *Encephalartos*.

(ii.) Megasporophylls peltate.

*Sporophyll terminating in two horns. *Ceratozamia*.

**Sporophyll with a spinous projection in the centre. Leaflets usually forked. *Macrozamia*.

***Megasporophyll flat outside.

†Microsporophyll not peltate. *Microcycas*.

††Microsporophyll peltate like the carpel (fig. 4). *Zamia*.

Recently some very interesting hybrids have been obtained by

FROM ENGLER AND PRANTL, "DIE NATÜRLICHEN PFLANZENFAMILIEN" (ENGELMANN)

FIG. 9.—GINKGO LEAF SHOWING VEINS

crossing various species of *Zamia* with others of the same genus and with species of *Encephalartos* and *Macrozamia*.

GINKGOALES

Ginkgo biloba, the maidenhair tree, is the solitary survivor of this ancient stock. As already mentioned it is almost extinct, but a few presumably wild trees have been recorded by travellers in parts of China. It is commonly cultivated in gardens of the far east, and is often also grown in North America and Europe and elsewhere. The trees are dioecious and may reach a height of 30 metres; they are freely branched and of pyramidal shape, with a smooth grey bark. The leaves (fig. 9) have a long slender petiole terminating in a fan-shaped lamina which may be entire or two-lobed or subdivided into several narrow segments. The veining is very characteristic and like that of many ferns, e.g., *Adiantum*; the lowest vein in each half of the lamina follows a course parallel

to the edge, and gives off numerous branches, which usually fork as they spread in a palmate manner towards the leaf margin. The foliage leaves occur either scattered on long shoots of unlimited growth or crowded at the apex of short shoots (spurs), some of which may subsequently elongate into long shoots.

The "cones," which are very unlike those of cycads and much reduced in comparison, are borne, usually several together, on spur shoots, in the axils of scale leaves. The "male" cone consists of a stalked central axis bearing a number of loosely disposed sporophylls. Each of these is formed of a slender stalk terminating in a small knob, from the inner side of which two

"ANNALS OF BOTANY," SEWARD AND GOWAN
FIG. 10.—GINKGO BILOBA: A. FEMALE OVULE; B. MALE CONE; C. SINGLE MICROSPOROPHYLL

(rarely three or four) ovoid sporangia hang obliquely (fig. 10). Each sporangium opens by a longitudinal slit, as in cycads (fig. 10). The first cell cut off by the microspore is a small and ephemeral prothallial cell. Subsequently all the same cells are produced as in cycads (fig. 11), and in the same order, but besides the extra prothallial cell there are some minor differences in the later development, e.g., the pollen tube is freely branched, the tube nucleus eventually passes back into the grain, which it does not do in cycads, and the two sperms are somewhat smaller than those of cycads, though their shape and structure are precisely the same.

spinous. In *Ceratozamia* the broad petiole base is characterized by the presence of two lateral spinous processes suggestive of stipules, and comparable with the stipules of Marattiaceous ferns.

Cones.—The "male" (or microsporangiate) cones of cycads (fig. 4) are very uniform in structure, and from one to a hundred may be produced in one season. Each consists of an axis bearing crowded, spirally disposed sporophylls, which are often wedge-shaped and angular, while in other cases they consist of a short, thick stalk terminating in a peltate expansion or prolonged upwards in the form of a triangular lamina (fig. 5). The crowded sporangia (pollen-sacs) are found on the lower side of the sporophyll and are often arranged in more or less definite groups (or "sori"). The sporangia break open when ripe by a slit radiating from the centre of the sorus. The sporangia are large, not unlike those of *Angiopteris* (a Marattiaceous fern) and their walls are several layers of cells in thickness. Each sporangium contains several oval spores which develop into pollen grains before they are set free. In this process each spore cuts off a small but persistent "prothallial cell," and immediately divides again to cut off an almost equally small "generative cell," the remaining nucleus, occupying the larger part of the spore cavity, being the "tube nucleus." In this 3-celled condition the pollen is shed.

The female plants bear cones which in most genera occur singly in the centre of the crown, but in *Encephalartos*, *Bowenia* and *Macrozamia* from two to several may be found. In some cases these female cones reach an enormous size, that of *Encephalartos Cafer* being up to a yard in length and weighing as much as 100 lb., while that of *Macrozamia Denisoni* may be as long, though its weight seldom exceeds 60 lb. The smallest cones are those of *Zamia*, that of *Zamia pygmaea* being sometimes less than 3 cm. in length. The sporophylls usually have some, often a close, resemblance to those of the male cone, and are clearly homologous with them.

The most primitive type is evidently *Cycas*, in which the sporophylls are arranged round the apex like a crown of foliage leaves and are definitely leaf-like in form. In *C. revoluta* and *C. circinalis* each may produce several laterally attached ovules, but in *C. Normanbyana* the sporophylls are shorter and the ovules are reduced to two. In all other genera the cone is a much more definite and compact structure, but the sporophylls of *Dioon* and *Stangeria* terminate in a leaf-like up-turned process, and are clearly comparable with those of *Cycas*. In some of the remaining genera the sporophylls are shorter with thick peltate heads, and each bears two ovules on the lower surface (fig. 6). The young ovule consists of a spherical or ovoid rather massive nucellus, sur-

rounded by the integument. The small round opening at the apex of the integument is known as the micropyle.

Fertilization and Development.—The pollen is carried by the wind, or very rarely, perhaps, by small beetles or other insects, to the micropyle and lodges there. Meanwhile the tip of the nucellus projects into the base of the micropyle in the form of a tiny beak, at the exact tip of which a fine hole appears, becoming somewhat wider below. This narrow but relatively deep hole, the "pollen chamber," being exactly below the centre of the micropyle, the pollen grains pass into it (or, in some cases at least, are drawn

into it by the evaporation of a drop of liquid which oozes out from the micropyle at the time of pollination, as in conifers) and the tip of the pollen chamber, as well as the micropyle, closes and hardens, thus completely enclosing the pollen grains, of which from half a dozen to a dozen are usually found here. Later these develop pollen tubes as described below.

While these changes are going on, a large cell, the megaspore, makes its appearance in the central region of the nucellus, rapidly

FIG. 7.—SEMI-DIAGRAMMATIC LONGITUDINAL SECTION OF A PART OF CYCAD OVULE BEFORE FERTILIZATION

increases in size, and ultimately absorbs the greater part of the nucellus. Its nucleus divides repeatedly and cells are produced from the peripheral region inwards, which eventually fill the spore cavity with a homogeneous tissue, the prothallus. From one to ten separate superficial cells at the apex of the prothallus now increase in size. Each cuts off a small cell at the top, which divides to form the small two-celled neck of the archegonium, the lower cell enlarging rapidly and becoming the egg-cell, its nucleus cutting off another small nucleus (which soon disappears) just before fertilization (fig. 7). In *Microcycas* a very large number of archegonia (up to 200 exceptionally) are produced all over the prothallus.

During the development of the prothallus the pollen chamber has enlarged both downwards and outwards, and eventually forms a fairly large chamber open below to the archegonia, which themselves lie at the bottom of a shallow depression in the apex of the prothallus, the "archegonial chamber." Each pollen grain at once begins to put out a tube which grows laterally into the nucellus just below its outer surface. The apical part of the nucellus is almost the only part remaining by this time, and is known as the "nucellar cap." Close inspection of the outer surface of the nucellar cap reveals several dark lines radiating from the beak outwards for about 2 mm. and these mark the positions of the pollen tubes. The "tube nucleus" of the pollen grain passes into, and remains in, the pollen tube, while the pollen grain hangs suspended by its tube in the pollen chamber (fig. 7). The "generative cell" divides to form another small sterile cell, the "stalk cell" and a much larger cell the "body cell," which continues to enlarge (as does that part of the tube to which the grain is attached) and finally divides once more into two equal hemispherical cells, in each of which a single very large and actively motile spermatozoid is produced (fig. 8). (In *Microcycas* 8 to 10 body cells and 16 to 20 sperms are formed in each pollen tube.) In the course of the last division two small bodies known as "blepharoplasts" make their appearance just outside the nucleus, and after division is complete one of them remains in each spermatozoid where it

FIG. 8.—CYCAD POLLEN TUBE WITH SPERMS IN MOTHER CELLS

gradually gives rise to a spiral band which passes round and round the outside of each sperm while from the outside of the band innumerable fine hair-like cilia are produced which, by their active movements, enable the sperms to swim about, first in the two cells within which they are formed, then in the part of the pollen tube adjacent to the grain after the cell walls break down, and finally in the film of moisture covering the archegonial chamber, after the bursting of the pollen tube. At last one penetrates the neck cells of an archegonium and so finds its way into the egg cell, where the sperm nucleus slips from its ciliated sheath of protoplasm and swiftly passes down to fuse with the large egg nucleus.

It is noteworthy that cycad sperms are the largest known in either plants or animals, and the only ones big enough to be definitely seen under ordinary lighting conditions, and while still living, with the naked eye, the largest of them reaching a diameter of more than a quarter of a millimetre. It is no less remarkable that sperms had been observed repeatedly in every other great group of both plants and animals (excepting *Ginkgo*) many years before they were ever seen in cycads, although the discovery of motile sperms in Gymnosperms had been predicted nearly 50 years earlier by the great German botanist Hofmeister. They were actually seen for the first time in *Cycas* in 1896 by a Japanese botanist, S. Ikeno, and shortly afterwards in *Zamia* by H. J. Weber, and since that time they have been carefully studied in most of the other genera.

Following fertilization, the fusion nucleus divides repeatedly till from 250 to about 1,000 nuclei are scattered through the protoplasm of the archegonium. These nuclei tend to be more closely aggregated at the base, and cell walls first appear in this region, thus forming a tissue at the base of each fertilized archegonium. An ephemeral tissue may also form throughout the archegonium, as happens in most genera, subsequently breaking down to form a cavity, or the centre of the archegonium may become a large vacuole at an earlier stage, as in *Cycas*. In either case the structure thus formed constitutes the proembryo. A compact group of cells at the extreme base forms the actual embryo, and the cells immediately above these elongate very much and eventually form a very long coiled and tangled suspensor which carries the embryo deep into the prothallus where it grows to about three-quarters of the length of the latter and absorbs about one-quarter of its tissue.

The mature embryo consists of an axis (the hypocotyl) terminated, at the end next to the suspensor, by a rudimentary root (the radicle) enclosed in a hard covering, the coleorhiza, and bearing at the other end a pair of large seed leaves or cotyledons, often fused together at their tips, and enclosing between them a minute terminal bud, the plumule. The integument of the ovule has now become the testa of the seed and is differentiated into three layers, an outer, thick, fleshy and brightly coloured one, in the inner part of which several vascular strands run up from the base, a thin hard woody layer, and a very thin inner fleshy layer containing a second set of vascular strands.

Anatomy.—The anatomy of the cycads presents many features of interest. Only a brief reference to one or two of the most striking of these is possible here. The wood is rather soft and laxly arranged and occupies a relatively small part of the thickness of the stem, though the vascular cylinder very slowly increases in thickness in the same manner as in woody Dicotyledons. Sometimes, as in *Cycas*, there is a double ring of vascular strands. In connection with the leaves two strands often branch off from the central cylinder on the opposite side to a leaf, pass spirally round in the cortex in opposed directions and pass into the petiole of that leaf, where they break up into a larger number of strands. This arrangement of leaf trace strands is peculiar to cycads, and the strands themselves are often known as girdles. For further anatomical details reference may be made to *The Living Cycads* by C. GINKGOALES

Ginkgo biloba, the maidenhair tree, is the solitary survivor of this ancient stock. As already mentioned it is almost extinct, but a few presumably wild trees have been recorded by travellers in parts of China. It is commonly cultivated in gardens of the far east, and is often also grown in North America and Europe and elsewhere. The trees are dioecious and may reach a height of 30 metres; they are freely branched and of pyramidal shape, with a smooth grey bark. The leaves (fig. 9) have a long slender petiole terminating in a fan-shaped lamina which may be entire or two-lobed or subdivided into several narrow segments. The veining is very characteristic and like that of many ferns, e.g., *Adiantum*; the lowest vein in each half of the lamina follows a course parallel to the edge, and gives off numerous branches, which usually fork as they spread in a palmate manner towards the leaf margin. The foliage leaves occur either scattered on long shoots of unlimited growth or crowded at the apex of short shoots (spurs), some of which may subsequently elongate into long shoots.

"ANNALS OF BOTANY," SEWARD AND GOWAN
FIG. 10.—GINKGO BILOBA: A. FEMALE CONE; B. MALE CONE; C. SINGLE MICROSPOROPHYLL

The "cones," which are very unlike those of cycads and much reduced in comparison, are borne, usually several together, on spur shoots, in the axils of scale leaves. The "male" cone consists of a stalked central axis bearing a number of loosely disposed sporophylls. Each of these is formed of a slender stalk terminating in a small knob, from the inner side of which two (rarely three or four) ovoid sporangia hang obliquely (fig. 10). Each sporangium opens by a longitudinal slit, as in cycads (fig. 10). The first cell cut off by the microspore is a small and ephemeral prothallial cell. Subsequently all the same cells are produced as in cycads (fig. 11), and in the same order, but besides the extra prothallial cell there are some minor differences in the later development, e.g., the pollen tube is freely branched, the tube nucleus eventually passes back into the grain, which it does not do in cycads, and the two sperms are somewhat smaller than those of cycads, though their shape and structure are precisely the same.

The "female cone" has the form of a long naked peduncle, bearing a single ovule on either side of the apex (fig. 10), the base of each being enclosed by a small saucer-shaped structure, the collar, which probably represents a sporophyll. The young ovule is very similar to that of cycads, a large pollen chamber occupying the apex of the nucellus. The early development of the prothallus takes place as in cycads, but eventually a short thick vertical col-

FROM HIRASE, "FÉCONDATION ET EMBRYOGÉNIE DE GINKGO BILOBA"
FIG. 11.—GINKGO BILOBA. A. RIPE POLLEN GRAIN. B. SECTION OF PROTHALLUS AND NUCULAR CAP AFTER POLLINATION

umn grows up from the centre and supports the remains of the nucellar cap, which develops much in the same manner as in cycads (fig. 11). There are usually only two archegonia. The sperms were first observed in 1898 by a Japanese botanist, S. Hirase. The proembryo is similar to that of cycads, and the general organization of the embryo and its relation to the seed are almost identical except that no suspensor is formed. The ripe seed is brownish yellow in colour, about the size of a small plum, and with the same layers in the testa as in cycads. The middle woody layer has usually two (sometimes three) longitudinal ridges. The seed falls soon after (rarely before) fertilization and before the embryo is fully developed.

The anatomical structure of *Ginkgo* is very similar to that of conifers, and the presence of a few large and much elongated secretory sacs in the pith of the stem is a specific character, while the two leaf traces passing direct into the petiole are also characteristic.

In its more obvious characters *Ginkgo* agrees with the conifers, and before the discovery of the motile sperms it was generally regarded as one. But in most of its more recondite characters it shows a very marked similarity to the cycads and may perhaps be more nearly related to them than to any other division of the Gymnosperms. In any case it is clearly intermediate in the sum of its characters between the cycads and the conifers, as well as showing distinct evidence of relationship with the fossil division Cordaitales, and is one of the links in the chain of evidence which goes to support the view that all the Gymnosperms had a common origin and a Filicinean ancestry.

CONIFERALES

General.—The plants included in this, the largest and most important, division of Gymnosperms are a less homogeneous assemblage of forms than the cycads, and include approximately 46 genera with about 470 species. While the cycads are all included in a single family of two tribes, the conifers may be conveniently distributed among five families, which agree, generally, in the following characters:—They are copiously branched trees or shrubs,

frequently of pyramidal form (as illustrated by the conventional "Christmas tree"—invariably a conifer). The leaves are always simple, and small compared with the size of the plant, usually linear, or short and scale-like, and generally persisting for more than one year. The plants are monoecious, e.g., *Pinus*, or dioecious, e.g., *Juniperus*, *Taxus*, and the cones are never terminal on the main stem. There is no perianth. The very regular monopodial branching is, perhaps, the most striking character of the majority of the conifers, of which a good example is seen in the giant Californian redwood, *Sequoia* (*Wellingtonia*) *gigantea*, the largest of the Gymnosperms, often seen in cultivation. Other conifers of this typical habit are many pines and firs, the monkey puzzle tree (*Araucaria imbricata*), the Norfolk Island pine (*Araucaria excelsa*), and the cedars and larches, several species exceeding 150 ft. in height. The yews and junipers and some other conifers grow as bushes, which in place of a main mast-like stem possess several repeatedly branched leading shoots. Dwarf forms are sometimes met with under arctic, alpine or other unfavourable conditions. Probably the smallest of these dwarf conifers is *Dacrydium laxifolium*, found on New Zealand moors, which may bear seed when only 2 in. high. Artificially dwarfed specimens of some species are commonly cultivated by the Japanese.

Leaves.—Nearly all conifers are evergreen and retain their leaves for from three to ten years; the larch (*Larix*), however, sheds its leaves each autumn, and those of the Chinese larch (*Pseudolarix Kaempferi*), which is also deciduous, turn a bright yellow before falling. In the swamp cypress (*Taxodium distichum*) the tree assumes a rich brown colour in the autumn, and sheds its leaves with the branchlets which bear them. Deciduous branches occur also in some other species. The leaves of conifers are usually characterized by their small size, e.g., the needle form represented by *Pinus*, *Cedrus*, *Larix*, etc., the linear flat or angular leaves, appressed to the branches, of *Thuja*, *Cupressus*, *Libocedrus*, etc.; all of which have a single median vein. The flat and comparatively

FIG. 12.—(A) NORMAL SHORT SHOOT OF PINUS. (B) "DOUBLE NEEDLE" OF SCIADOPITYS. (C) OVULIFEROUS SCALE OF LARIX OR PINUS

broad leaves of *Araucaria imbricata*, *A. Bidwillii*, and a few species of the southern genus *Podocarpus*, are traversed by several parallel veins, as are the still larger leaves of *Agathis*, which may reach a length of several inches. In addition to the foliage leaves several genera also possess scale leaves of various kinds, represented by bud-scales in *Pinus*, *Picea*, etc., which frequently persist for a time at the base of a young shoot which has pushed its way through the yielding cap of protecting scales, while in some conifers the bud-scales adhere together, and after being torn near the base are carried up by the growing axis as a thin brown cap. The cypresses, Araucarias and some other conifers, have no true bud-scales; in some species, e.g., *Araucaria Bidwillii*, the occurrence of small foliage leaves, which have functioned as bud-scales, at intervals on the shoots, affords a measure of seasonal growth. The occurrence of long and short shoots is a characteristic feature of pines, cedars and larches. In *Pinus* the needles occur in pairs, or in clusters of three or five at the apex of small and inconspicuous short shoots of limited growth (spurs). The spur is enclosed at its base by a few scale leaves, and is borne on a branch of unlimited growth in the axil of a scale leaf. In some junipers, cypresses, etc., in which small leaves appressed to the stem are normal in adult plants, examples occur in which these leaves are replaced by the slender needle-like leaves, standing out more or less at right angles to the branch, which are characteristic of the seedling stage. Such cases are often

seen in cultivation, and are usually named "Retinospora," though this name does not denote a true genus, but merely the persistent juvenile forms of *Thuja*, *Juniperus*, *Cupressus*, and other trees of the same type.

A remarkable and unique leaf is found in the umbrella pine (*Sciadopitys verticillata*). These leaves are produced singly on whorls of spur shoots and bear traces, in the grooved surface and in the possession of two separate veins, of an origin from pairs of needle leaves. A peculiarity of these leaves is the inverse orientation of the vascular tissue; each of the two veins has its phloem next the upper, and the xylem towards the lower, surface of the leaf; this unusual position of the xylem and phloem is explained by regarding the needle of *Sciadopitys* as composed of a pair of leaves on a short shoot, fused by their upper margins (fig. 12). The short shoots of the cedar and larch are stouter structures bearing an indefinite number of leaves, and are not shed with the leaves as are the spurs of pines and *Sciadopitys*. In the genus *Phyllocladus* (New Zealand, etc.) there are no green foliage leaves, but in their place flattened branches (phylloclades) borne in the axils of small scale leaves. The cotyledons are usually two in number in conifers, but occasionally more, as in cedars and pines, reaching as many as 15 in the last named.

FROM ENGLER AND PRANTL, "DIE NATÜRLICHEN PFLANZENFAMILIEN" (ENGELMANN)

Cones.—A typical "male" cone consists of a central axis bearing from less than a dozen to a very large number of sporophylls which usually follow the leaf arrangement, i.e., they are generally spirally arranged except in most of the Cupressaceae where they are opposite or whorled. The sporophyll (fig. 13) is composed of a slender stalk, terminating in a knob or scale and bearing from two to 15 pollen-sacs on its lower surface. The larger number of sporangia (6 to 15) are characteristic of *Araucaria* (fig. 13) and *Agathis* in which the sporangia are also peculiar in their large size and in being long, narrow and free. They may thus be compared to the sporangia of the horse-tails (*Equisetum*). In the yew (*Taxus*) the stalk is attached to the centre of a large more or less circular expansion bearing four to eight pollen-sacs on its inner surface, but which are also fused with the stalk, not hanging freely like those of *Araucaria*. The sporangia usually open by a longitudinal, occasionally by a transverse, slit.

The structure of the "female" cone differs considerably in the five families of conifers which are as follows:—

- | | |
|--------------------|----------------------------------|
| I. ARAUCARIACEAE. | 2 genera and about 18 species. |
| II. PODOCARPACEAE. | 7 genera and about 100 species. |
| III. PINACEAE. | 10 genera and about 200 species. |
| IV. CUPRESSACEAE. | 22 genera and about 140 species. |
| V. TAXACEAE. | 5 genera and about 12 species. |

In the first family—Araucariaceae—the female cone, especially when young, has often a close resemblance to the male, and may be interpreted as homologous with it. On this view it is regarded as an axis bearing a large number of sporophylls, closely packed and spirally arranged. Each sporophyll consists of a scale-like basal part and a terminal up-turned leafy part—the lamina. Embedded in the scale with its apex facing the cone axis is a single large ovule. The nucellus is long and narrow and projects beyond the micropyle. In *Araucaria* (but not in *Agathis*) a *ligule* projects from the upper surface of the scale beyond the base of the ovule.

In the Podocarpaceae the cone is often much reduced, ranging from an axis with a small number of sporophylls, each bearing an inverted ovule, as in *Microcachrys*, *Saxegothea* (fig. 15), and some species of *Dacrydium*, to the form found in other species of *Dacrydium* and in *Podocarpus*, where the number of fertile scales is reduced to two or one, small in comparison with the large inverted ovules. In the latter case, broadly speaking, the cone practically

consists eventually of one or two naked ovules, though traces of the subtending scales can always be found. *Phyllocladus* and *Pherosphaera* are exceptional in having erect (not inverted) ovules. The ovules of the Podocarpaceae usually have a second, outer, integument, the epimatium, wholly or partially enclosing the inner (fig. 15).

The female cones of the third family, Pinaceae, are better known, but much more difficult to interpret. To this family most of the common northern conifers belong, such as the pines, spruces, silver firs, cedars and larches. The last-named will serve as a type. Here the cone consists of an axis bearing a large number of closely set, spirally arranged *pairs* of scales. Of the two scales in each pair one is immediately above the other (i.e., in its axil), the lower being bract-like and sterile and known as the carpellary scale or *bract scale*, the upper bearing the ovules (usually two) on its upper surface and being known therefore as the *ovuliferous scale*. The small ovules are fused to the surface of the scale at its proximal end, and lie with their micropyles facing the axis. In the very young cone the two sorts of scales are of similar size; after pollination the ovuliferous scale grows considerably, and is always thicker than the subtending bract scale. The latter, in the larch, at first grows in length faster than the former and so projects beyond the ovuliferous scale in the older cone, but in most cases the bract scales either remain quite abortive after pollina-

FIG. 14.—(A) MICROPYLE OF *LARIX EUROPAEA* FULL OF POLLEN GRAINS; (B) SINGLE POLLEN GRAIN FROM MICROPYLE OF *LARIX EUROPAEA*

tion, as in the pine, or grow much more slowly than the ovuliferous scales, the latter alone showing on the outside of the cone. In both cases the scales fuse together externally after pollination, forming a continuous outer covering to the cone and effectually enclosing the ovules, which remain hidden until after the seeds are ripe, often for one, two or more years.

It is not possible to explain here the various views which have been held as to the nature of the ovuliferous scale (the bract scale is clearly homologous with a subtending leaf) but that which

has been most generally accepted was due, in the first place, to Alexander Braun in 1842. He explained the ovuliferous scale as representing the two leaves of a spur shoot, fused (as in the double needle of *Sciadopitys*), by their posterior (adaxial) margins. The usual two ovules would thus be borne one on each leaf (sporophyll), as in the preceding families. This explanation also takes account of the *inverted vascular supply* of the ovuliferous scale, again paralleled in the leaf of *Sciadopitys* (fig. 12). In abnormal cones the ovuliferous scale is sometimes replaced by a dwarf shoot bearing two leaves, which lends further support to Braun's hypothesis.

In the next family, Cupressaceae, the more typical genera appear to have only one kind of scale, while others, belonging to the tribe Taxodioideae, often have a ligule-like structure on the upper surface of the scale (e.g., *Cunninghamia*). The ovules are borne close to the base of the scale, and are usually erect, less commonly inverted. The number borne on one scale is very variable, but from three to seven is usual. Anatomical examination of the scale, however, always indicates the presence of *two sets of vascular strands of which the upper is inverted*; of which the most obvious explanation is that the cone scale represents the bract and ovuliferous scales of the Pinaceae partially or wholly fused together. There are certain difficulties in this apparently simple explanation, but nevertheless it is a generally accepted view.

In the last family, Taxaceae, the female cone is an even more reduced structure than in the Podocarpaceae, consisting usually of a very short axis bearing few or many scale leaves at its base and apparently terminating in a single erect ovule. In reality the apparently terminal ovule may be in the axil of one of the uppermost scales. The whole structure is so reduced that it is difficult, and perhaps unprofitable, to explain it in terms of the other four families, but at least it gives little indication of the complexity characteristic of Pinaceae and Cupressaceae. Unlike cycads, *Ginkgo* and the majority of other conifers the ovule has two integuments, the outer more or less fleshy, as in the red "aril" of the yew seed.

Fertilization and Development.—The structure of the pollen grain is not identical in the different families of conifers, the differences partly concerning the prothallial cells, which are from two to several in number and form a persistent tissue in both Araucariaceae and Podocarpaceae (except *Pherosphaera*), two and quite ephemeral in Pinaceae (except in *Sciadopitys* where they are absent), and entirely wanting in Cupressaceae and Taxaceae. The remaining divisions in the pollen grain and tube correspond to those in cycads and *Ginkgo*, i.e., a tube nucleus and generative cell

FIG. 15.—SCALE AND OVULE OF SAXEGOTHEA

are formed, after which the pollen is usually shed (though this may happen before these cells are differentiated as in *Widdringtonia* or after the division of the generative cell to form stalk and body cells as in *Larix* and most Pinaceae [fig. 14]). The pollen is carried by the wind to the neighbourhood of the ovule. In Araucariaceae it germinates on the scales of the female cone, the tube eventually growing into the nucellus; in *Saxegothea* (Podocarpaceae) it germinates on the stigma-like apex of the nucellus (fig. 15), and in most other conifers it is caught in the *pollination drop* which is extruded from the open micropyle of the young

ovule and on evaporation of which the pollen is drawn down to the apex of the nucellus. The pollen tube at once begins to grow into the nucellus, but downwards, towards the prothallus, not laterally as in cycads, and into the tube pass, not only the tube nucleus but also, in all cases, the stalk nucleus and body cell. No

FIG. 16.—SEMI DIAGRAMMATIC LONGITUDINAL SECTIONS OF PROTHALLUS WITH NUCELLUS (OR NUCELLAR CAP) OF ARAUCARIA (A), PINUS (B), TETRACLINIS (C) AND ACTINOSTROBUS (D)

well organized pollen chamber is formed in the nucellus of conifers, but sometimes a few cells at its upper end break down and so produce a saucer-shaped depression (fig. 16). The body cell divides to form two *non-motile* male cells, which in Cupressaceae are exactly equal and both functional, but in the other families are usually unequal, and only the larger functional.

In the young ovule a single functional megaspore develops, usually the lowest of a row of three or four, formed from a mother-cell as in cycads and practically all other seed plants. Exceptionally, as in *Taxus*, *Callitris* and *Ptherosphaera*, two or more megaspores may begin to develop. The formation of the prothallus takes place almost exactly as in cycads, but it is smaller, usually much smaller, in the conifers, as are also the archegonia. The latter are few, and formed (as in cycads) from separate superficial cells at the apex in Podocarpaceae (except *Ptherosphaera* and *Microcachrys*), Pinaceae and Taxaceae (fig. 16); rather more numerous and more scattered, and more or less lateral, in *Ptherosphaera* and in Araucariaceae (fig. 16), and in a single apical complex of 6 to 24 (all in contact with other archegonia of the group) in *Microcachrys* and in most Cupressaceae (fig. 16). In the remaining Cupressaceae, including *Sequoia* and the tribe Callitroideae, the archegonia are very small and numerous, usually deep-seated, and arranged in from one to several groups (in contact with each other in any one group) placed laterally along the prothallus, and never at, or very close to, the apex, which is usually pointed (fig. 16). The number of such archegonia may be up to about 60 in *Sequoia* or as many as 100 in *Widdringtonia*. A curious feature of these forms is that the size of the egg nucleus is about the same as that of the male nucleus at the time of fertilization, and in *Actinostrobus* (fig. 16) even the whole archegonium may be no larger than the male cell, so that we have here what practically amounts to a case of *isogamy*, of which no other example can be found in any plant of higher organization than the Algae and Fungi. It should be noted that in all conifers, in marked contrast with the preceding divisions, the male cells possess no cilia, and are carried by the growth of the pollen tube either into the archegonium itself or to a point very close to it. It is usual to describe the male cells as non-motile, but it is not clear that this is always strictly accurate as they may pass from the tube into the archegonium without being actually carried into it, which seems to imply some limited power of independent movement, possibly of an amoeboid nature. In the Araucariaceae, as in *Sequoia* and the Callitroideae, male and female nuclei are equal in size at the time of fertilization. In most other conifers the male nucleus is distinctly smaller than the female, while in the family Pinaceae it is only about one-hundredth of the volume of the female nucleus.

In conifers the neck of the archegonium is always composed of more cells than the two characteristic of cycads, but the actual number varies widely, from about four in one tier to about a dozen or more in several tiers. Speaking generally it is less conspicuous in the Cupressaceae than in the other families.

The early development of the embryo varies a good deal in the different families. In *Araucaria* and *Agathis* 32 or more free nuclei are formed in the protoplasm of the archegonium. These nuclei then arrange themselves into a central group (of two tiers) and a peripheral enveloping layer, after which walls are laid down between them. The structure thus formed is the proembryo and completely fills the archegonium. The central group alone forms the embryo, the basal cells of the peripheral layer functioning as a protective cap while the cells nearest the neck elongate to form a suspensor.

The case of the Pinaceae is best known. Here only four free nuclei are formed which pass to the base of the archegonium and there divide to form a basal layer of four cells and an upper tier of four nuclei. The latter repeat the process, resulting in two layers of cells and one of four nuclei above. Lastly the cells of the lowest tier divide once more giving three tiers of four cells each with one above of four nuclei. This is the structure of the proembryo and it occupies approximately the basal one-third or one-quarter of the archegonium. The tier of nuclei has no obvious function, the next tier may serve to prevent the suspensor cells growing back into the archegonial cavity, the lowest tier but one elongates enormously, forming the suspensor, while the basal tier forms the true embryo. The latter eventually becomes differentiated into a hypocotyl terminating in a radicle at the suspensor end and a whorl of, usually, several cotyledons at the other end, surrounding a central plumule. It sometimes happens that the four suspensor cells become separated from one another, along

with the corresponding embryo cells, the latter then forming four separate embryos instead of one, though in any case not more than one embryo in a prothallus normally reaches maturity.

In the Podocarpaceae and in the more typical Cupressaceae (excluding *Sequoia* and the Callitroideae) proembryo development is similar to that in Pinaceae except that eight free nuclei are formed before cell formation and that the tiers are much less regular both in number and arrangement, the basal often consisting of only a single cell; and the embryo has usually only two cotyledons. In both cases the proembryo only occupies the basal part of the archegonium. The family Taxaceae only differs from the two preceding in the fact that the proembryo fills the archegonium, with the exception that the genus *Cephalotaxus* develops a protective cap like that of Araucarians.

In *Sequoia* and the Callitroideae cell formation takes place earlier than in any other forms (in *Sequoia* at the first division) and the proembryo fills the archegonium. The embryo develops from a single cell which may be that at the base of the archegonium (*Sequoia*) or may be cut off, at the end facing the base of the prothallus, from any of the lower cells of the proembryo (*Actinostrobus*). In either case the larger cell adjacent to the embryo cell becomes the suspensor.

In spite of these marked differences in the early embryo development there is a considerable uniformity in the structure of the seed in conifers. In most cases the testa ripens dry and woody, as the outer fleshy layer of the cycads only develops to a very small extent and finally withers away. Within the testa the nucellus is scarcely noticeable except as the withered remains of the nucellar cap, while the prothallus is always packed full of starch and so becomes somewhat brittle. The embryo normally lies symmetrically in the centre of the prothallus and is about two-thirds of its length and perhaps about one-tenth of its volume. In several conifers the seeds are winged, but while the wing is formed, in Pinaceae, from part of the tissue of the ovuliferous scale, in Cupressaceae (when present) it is part of the integument of the ovule (e.g., *Widdringtonia*). In Taxaceae and some Podocarpaceae the seeds have a fleshy covering, not always of the same nature, and in *Microcachrys* (Podocarpaceae) the cone scales themselves become fleshy, thus forming a "fruit" something like a small raspberry. In the juniper also (Cupressaceae) the fertile scales become fleshy, thus forming a berry-like "fruit."

Anatomy.—One of the most striking features of conifer anatomy is the occurrence of long cylindrical intercellular spaces lined with thin-walled, resin-secreting cells and known as resin canals. These are frequently present in all parts of the plant and are never entirely absent except in *Taxus* and in *Dacrydium laxifolium*. In the former isolated resin-secreting cells occur here and

FROM ENGLER AND PRANTL, "DIE NATÜRLICHE PFLANZENFAMILIEN" (W. ENGELMANN)

FIG. 17.—RESIN CANAL IN PINUS SYLVESTRIS LEAF

there in the tissues, but in the latter even these appear to be lacking. The resin canals are most frequently found in the cortex and have a characteristic structure, the epithelial cells which secrete the resin being in turn surrounded, as a rule, by a ring of much more conspicuous thick walled protecting cells (fig. 17). In many genera resin canals are also found in the wood, as in *Pinus*, while sometimes they are restricted to the cone axis, as in *Sequoia*. They are nearly always present in the leaves, often below the vascular bundle. Although resin canals are a characteristic feature of the conifers they are by no means peculiar to them, being equally

distinctive of some tropical families of flowering plants (e.g., Anacardiaceae) and occasional plants outside those families such as sunflower and ivy.

The phloem always includes sieve tubes without associated companion cells (though phloem-parenchyma cells with albuminous contents are present, and with pitted areas chiefly on their lateral walls). In the Pinaceae the phloem consists solely of sieve tubes and phloem parenchyma, but in most other forms concentric cylinders of bast fibres occur in regular alternation with the functional phloem.

Coniferous wood is homogeneous in structure, consisting almost entirely of tracheids with circular (rarely polygonal) bordered pits on the radial walls. Xylem parenchyma is never abundant, but traces of it are present in many genera. In *Pinus* there is no wood parenchyma except in association with the numerous resin canals scattered through the wood. The medullary rays consist of a single layer of cells except in certain Pinaceae (where some of them are fusiform in section, enclosing a single horizontal resin canal) and have usually a complex structure. The margins, both upper and lower, of that part of the ray which lies in the xylem, are often composed of horizontally elongated tracheids with irregularly folded walls and bordered pits, while the central rows of cells are parenchymatous and thin-walled, but usually pitted. In the phloem the marginal ray tracheids are replaced by irregularly lobed albuminous cells.

Root.—The roots of many conifers possess a narrow band of primary tracheids with a group of slender protoxylem elements along either margin (diarch). In other cases the primary xylem is triarch or tetrarch (*Sequoia*) or even polyarch. An old root approximates closely to a stem in structure, but the annual rings are often less clearly marked and the tracheids larger and thinner-walled. The primary tissues are, of course, differently arranged, but are apt to become obliterated with age.

Stem.—The primary vascular bundles in a young conifer stem are collateral, and, like those of a Dicotyledon, they are arranged in a circle round a central pith and enclosed by a common endodermis. Secondary thickening begins at an early stage and continues throughout the life of the plant with seasonal variations and interruptions resulting in the normal appearance of clearly defined annual rings, as in most woody Dicotyledons. The differences of structure met with in conifer stems are sometimes affected by the conditions (including climate) under which they are grown, and are more often distinctive of species than of genera or families. There are, however, certain characters of the wood which are of greater significance. For instance the secondary tracheids of nearly all conifers (fig. 18) have a single row of separate bordered pits (rarely of two rows with the pits of the two rows opposite). This type of wood is distinctive of Podocarpaceae, Pinaceae and Cupressaceae. In *Araucaria* (fig. 18) and *Agathis* the bordered pits are in one, two or three rows on the radial walls and, being in contact, are polygonal in shape, and the pits of adjacent rows are alternate and not opposite. In *Taxus* (fig. 18) the normal type of bordered pit occurs, but in addition conspicuous spiral thickening-bands are met with. It is doubtless these which give to the wood of the yew its well-known strength and elasticity, recognized by the mediaeval English when they used it for their bows, which were the most efficient weapons of that period.

Leaf.—The cotyledons have each a single vascular strand ex-

cept in *Podocarpus*, which has two, and in Araucarians where there are four or more. In the latter there are also several resin canals, one or two of which are also found in *Pinus*, though absent in most other forms. The adult leaves (fig. 20) have a single median vein except in *Agathis*, several species of *Araucaria* (fig. 20 C) and a few of *Podocarpus*, which have several parallel veins. In some pines (e.g., *Pinus* and *Abies* [fig. 20]) this vein includes two vascular bundles, but in others, and in all

FIG. 19.—STOMA OF *PINUS SYLVESTRI*

Cupressaceae (fig. 20) and Taxaceae and in all podocarps, except the few species of *Podocarpus* already mentioned, there is only a single vascular strand. In all cases the leaf trace leaves the central cylinder as a single strand, unlike *Ginkgo* and the cycads, but in *Araucaria*, etc., this strand splits into several in its passage through the cortex. In most genera one or more resin canals are found in the leaf, and another equally distinctive feature is the presence, generally on the flanks of the vascular strand, of a few isodiametric tracheids known as "transfusion tracheids." Sometimes there are also horizontally elongated transfusion tracheids extending towards the leaf margin. A noteworthy feature is the common occurrence of hypodermal fibres, but their presence and extent is partly dependent on the light conditions under which their development takes place; e.g., a pine needle grown in continuous light lacks the usual hypodermal fibres, as well as differing in some other details. In *Pinus* and *Cedrus* the homogeneous mesophyll is characterized by the infolding of the cell walls. In many leaves, such as those of *Abies* (fig. 20) and *Larix* there is both palisade and spongy parenchyma. In *Araucaria imbricata* (fig. 20) a palisade layer occurs in both upper and lower parts of the mesophyll, and resin canals are found between the veins, while in the multi-nerved species of *Podocarpus* (section *Nageia*) a canal occurs below each vein. This position (below the vein) is that usual for the single resin canal of many forms (fig. 20), while in *Larix*, *Abies*, etc., two canals run through the leaf parallel to the margins (fig. 20). Each stoma is normally sunk at the base of a pit (fig. 19), and the stomata are frequently arranged in rows, their position being marked by two or more bands of wax on the surface of the living leaf.

Geographical Distribution.—Most conifers grow in forests, either alone or mixed with angiospermous trees, forming one of the characteristic features of the vegetation in temperate and alpine regions. Since a large proportion of the cold temperate lands lies in the northern hemisphere it is easy to understand why the chief home of the Coniferales is in the north, where certain species occasionally extend into the arctic circle and beyond the tree limit, e.g., *Juniperus nana*. The tree limit in northern Europe is chiefly marked by conifers (*Picea*, *Larix*, *Abies*, *Pinus*, etc.), and many are abundant in North America, such as *Juniperus virginiana*, *Taxodium* and several pines on the eastern side; *Pseudotsuga*, *Sequoia*, other pines, etc., on the west; while *Picea*, *Larix*, *Abies*, *Tsuga*, *Taxus* and *Pinus strobus* are characteristic forms throughout. In the Mediterranean region occur *Pinus maritima*, *P. pinea* and other species, cedars and cypresses. In Japan and China are a number of small endemic genera such as *Cryptomeria*, *Cunninghamia*, *Sciadopitys*, *Cephalotaxus* and *Pseudolarix*. In the Himalayas are *Cedrus*, *Taxus* and endemic species of *Abies*, *Pinus*, etc. Apart from high altitudes few conifers are found in the tropics, but various endemic types are met with in the south, of which *Podocarpus* is most widely distributed, while *Widdringtonia* is peculiar to South Africa and a considerable number of characteristic genera are found in Australasia, such as *Callitris*, *Agathis*, *Dacrydium*, *Microcachrys*, *Athrotaxis* and *Araucaria*, most of which are endemic. The last named, however, occurs in South America as well, where *Fitzroya* and *Saxegothea* are also met with, chiefly in the Andes.

Classification.—In conclusion a brief account of the characters of the five families and their tribes, and a key to the principal genera of each may be given:

FROM A. & C. BAKER & SMITH, "PINES OF AUSTRALIA"

FIG. 18.—TRACHEIDS: *ARAUCARIA* (LEFT); *TAXUS* (CENTRE); *PINUS* (RIGHT)

FIG. 20.—(A) LEAF OF *ABIES PUNGENS*; (B) *JUNIPERIS COMMUNIS*; (C) *ARAUCARIA IMBRICATA*; (D) PART OF *ARAUCARIA IMBRICATA* ON LARGER SCALE

I. **ARAUCARIACEAE.** Large trees. Both male and female cones rather large. Microsporophylls with numerous long, narrow, pendulous pollen sacs. Megasporophylls numerous, simple and bearing solitary ovules embedded in the tissue. Nucellus extending beyond the integument. Prothallus with separate scattered archegonia, usually more or less lateral. Several prothallial cells in the pollen grain. Tracheids with multiseriate pitting.

*Dioecious. Megasporophyll with a ligule. *Araucaria*.

**Monoecious. Megasporophyll without a ligule. *Agathis*.

II. **PODOCARPACEAE.** Trees, shrubs and small undershrubs, mostly dioecious. Megasporophylls not numerous in the cone, each bearing a single, usually inverted ovule. Male cones with spiral or sometimes whorled sporophylls, each with two pollen sacs. Pollen often winged, with a group of two or more persistent prothallial cells (except in *Pherosphaera*). Archegonia separate, each with its own jacket cells, as in *Araucariaceae*, but apical, not lateral (except in *Pherosphaera* and *Microcachrys*).

*Flat expanded branches and no true foliage leaves.

Ovules erect. *Phyllocladus*.

**Normal foliage leaves.

†Megasporophylls solitary or in pairs, or a few very laxly arranged on a strobilus, but never joining to cover the more or less inverted ovules.

◉Pollen winged. Ovules always fully inverted, on a swollen stalk and solitary or in pairs. *Podocarpus*.

◉◉Pollen not winged. Ovule sessile and not fully inverted. *Dacrydium*.

††Megasporophylls in a cone, growing together so as to enclose the ovules.

◉Ovules more or less inverted. Epimatium present.

§Monoecious. Leaves needle-like. *Saxegothea*.

§§Dioecious. Leaves scale-like. *Microcachrys*.

◉◉Ovules erect and axillary. No epimatium. *Pherosphaera*.

III. **PINACEAE.** Trees and shrubs, usually monoecious. Male

cones like those of *Podocarpaceae*, with two pollen sacs to each sporophyll. Female cone compact with many pairs of scales, the upper of each pair bearing two, or rarely more, ovules. Archegonia separate, each in its own jacket cells, as in *Podocarpaceae*.

A. Pollen with no prothallial cells. A single grooved leaf on each short shoot with two veins, one either side of the groove. Several ovules on the ovuliferous scale. Tribe 1. *Sciadopitoideae*. *Sciadopitys*.

Except for the separate archegonia, could be equally well placed in the *Cupressaceae*.

B. Pollen with two ephemeral prothallial cells. Leaves with a single vein. Two ovules on each ovuliferous scale. Tribe 2. *Abietoideae*.

(i.) Leaves almost entirely borne on spur shoots.

*From one to five leaves (the number more or less constant in each species) on each short shoot. *Pinus*.

**A tuft of more than five leaves on each spur shoot.

†Leaves not deciduous. *Cedrus*.

††Leaves deciduous.

◉Cone scales deciduous. Rim of micropyle spreading. Pollen winged. *Pseudotsuga*.

◉◉Cone scales persistent. Rim of micropyle infolded. Pollen not winged. *Larix*.

(ii.) Leaves borne on branches of unlimited growth.

*Bract scales three-lobed, and projecting beyond the ovuliferous scales. Rim of the micropyle infolded. *Pseudotsuga*.

**Bract scales not three-lobed even when longer than the ovuliferous scales. Rim of the micropyle spreading.

†Cones pendulous. Cone scales persistent.

◉Pollen sacs dehisce longitudinally.

Pollen winged. Cones large. *Picea*.

◉◉Pollen sacs dehisce transversely.

Pollen globose. Cones small. *Tsuga*.

††Cones erect. Cone scales deciduous. Bract scales often longer than the ovuliferous scales. Leaves flat. *Abies*.

IV. CUPRESSACEAE. Trees or shrubs, often dioecious. Only one kind of scale in the female cone as a rule, but sometimes with outgrowths on the upper surface. Number of fertile scales usually much smaller than in Pinaceae, often only from two to six or eight. Ovules inverted or more often erect, commonly more than two to each fertile scale. Archegonia in one or more groups, not solitary. Male cones small with usually three or more pollen sacs to each sporophyll. Pollen grain without prothallial cells. Leaves usually small, not infrequently dimorphic, as in *Juniperus chinensis*.

A. Leaves opposite or whorled. Ovules erect.

(i.) Archegonia in a single apical group. Tribe 1. Cupressoideae.

*Cone scales ripening fleshy. *Juniperus*.

**Cone scales ripening woody.

†Cone scales peltate. *Cupressus*.

††Cone scales not peltate.

°Cone scales imbricate.

a. Four or five seeds to each scale. *Thujaopsis*.

β. Usually two seeds to each scale.

§Two fertile scales. *Libocedrus*.

§§Four fertile scales. *Thuja*.

°°Cone scales valvate. *Tetraclinis*.

(ii.) Archegonia never apical, but in one or more lateral groups, usually deep-seated. Tribe 2. Callitroideae.

*Scales slightly imbricate (imperfectly known; may prove to belong to the preceding tribe). *Fitzroya*.

**Scales valvate.

†Fertile scales four in decussate pairs. *Widdringtonia*.

††Fertile scales six in alternating whorls of three.

°Cone with a number of sterile bracts at the base. Fertile scales all equal. *Actinostrobus*.

°°No sterile bracts at base of cone. Fertile scales unequal. *Callitris*.

B. Leaves spirally arranged.

(i.) Archegonia in a single apical complex. Tribe 3. Taxodioideae.

*Leafy branchlets deciduous. *Taxodium*.

**Leaves, cone-scales deciduous. *Glyptostrobus*.

***Neither leaves nor branchlets deciduous.

†Seeds erect. *Cryptomeria*.

††Seeds inverted.

°Fertile scales with a narrow transverse membrane (ligule) above the seed. Leaves lanceolate. *Cunninghamia*.

°°Fertile scales with a transverse ridge above the seed. *Athrotaxis*.

(ii.) Archegonia never apical. Tribe 4. Sequoideae. *Sequoia*.

It is quite possible that tribes 3 and 4 above should be merged in tribes 1 and 2 respectively, the distinction based on the leaf arrangement being probably unimportant, and not always constant.

V. TAXACEAE. Small trees and shrubs, usually dioecious, with much reduced female cones often consisting of single naked erect ovules subtended by a number of bracts, the ovules usually with an outer fleshy integument. Archegonia as in Pinaceae. Male cones small with peltate or crested sporophylls each bearing from two to seven, or more pollen sacs. Pollen grains without prothallial cells. Leaves usually free and blade-like.

*One or two erect ovules borne on a small fleshy fertile scale which becomes abortive as the seeds ripen. No aril. *Cephalotaxus*.

***"Cone" reduced to a naked ovule. Aril present.

†Microsporophylls crested, with two to four pollen sacs. *Torreya*.

††Microsporophylls peltate with four to eight pollen sacs. *Taxus*.

GNETALES

These are perennial, normally dioecious plants with opposite simple leaves. The perianth of one or two whorls is distinctive, and sharply contrasts this division with other Gymnosperms. The cones are more complex than in other forms, consisting of an axis bearing decussate pairs of bracts or a number of superposed whorls of bracts, each whorl connate in a cup-like form. In either case the ovulate or staminate structures, which for convenience we may call "flowers," are axillary to these bracts. The flower always consists of one or two pairs of free or connate scales, the perianth, enclosing either a single ovule with a long projecting micropylar tube, or from one to six stamens. It is evident that it is the flowers of Gnetales, especially the female flowers, which are equivalent to the cones of conifers (e.g., compare the female cone of *Torreya*) and not the whole "cone," which might well be called a compound cone, and which is also comparable to the catkin-like inflorescence of certain flowering plants.

In their anatomy also the Gnetales show a marked resemblance to angiosperms, as, though the phloem remains typical of gymnosperms in general, true vessels, like those of the flowering plants, are associated with typical gymnospermous tracheids in the wood, and there are no resin canals.

The division includes only three genera, which are so entirely unlike in appearance as to suggest at first sight that each must be regarded as the type of a separate family. But detailed study of development and anatomy has indicated a very close similarity in the former respect between two of the genera, and at least a partial explanation of their complete dissimilarity in appearance, while emphasizing the divergence of the third. They are therefore considered here as forming two families, as follows:—

I. EPHEDRACEAE. Much branched small-leaved xerophytic shrubs. Ovule with two integuments containing a prothallus with archegonia, similar to that of conifers. *Ephedra*.

II. GNETACEAE. Vegetative region of the plant unbranched or sparingly branched. Ovule with one or two integuments and containing a prothallus which does not form archegonia. Leaves large.

A. Tribe Welwitschioideae. Plant tuberous and chiefly underground, developing only two enormously long and straggling, parallel-veined leaves after the cotyledons. *Welwitschia*.

B. Tribe Gnetoideae. Plant a tree or large woody climber, with numerous net-veined leaves indistinguishable from those of ordinary dicotyledons. *Gnetum*.

It seems evident that *Ephedra*, both in general habit and in the possession of archegonia is intermediate in character between the conifers (having points of resemblance to both Cupressaceae and Taxaceae), and the Gnetaceae, while *Gnetum* has many points of similarity to the true flowering plants. Most botanists have hesitated (no doubt rightly) to look upon the Gnetaceae as the direct ancestors of the flowering plants, but it is not altogether unlikely that both may have originated from the same stock, which was perhaps not very different from *Gnetum*. It is indeed a very surprising fact that the geological history of the Gnetales is unknown.

Ephedra is the largest genus of Gnetales, with about 35 species, and the only one represented in Europe. It is confined to more or less arid warm-temperate and tropical regions and one species is common on sand dunes along parts of the Mediterranean coast. The finer branches are green; the surface of the long internodes is marked by fine longitudinal ribs; and at the nodes are borne pairs of small, partially connate scale leaves, the general appearance being similar to that of a stem of *Equisetum* or a twig of *Casuarina*. Some of the branches bear pairs of small cones in the axils of the scale leaves. The cone scales are broad and imbricate. Each male flower (fig. 21) consists of an inconspicuous

perianth, composed of two more or less concrescent bracts, enclosing an axis projecting beyond the perianth and terminating in two (sometimes more, up to six or eight) sporangia. The resemblance of this structure to a stamen is obvious, but it is no less clearly homologous with the microsporophyll of conifers.

The female flower is enveloped in a closely fitting perianth of two more or less connate bracts, as in the male flower. This perianth encloses a single ovule with two integuments, the inner, which is not more than two cells thick, prolonged upwards as a beak-like micropyle, the outer, which is thicker and later becomes woody, only reaching about half way up the micropylar beak. The micropyle secretes a pollination drop, as in conifers.

A prothallus is organized exactly as in conifers, the two to five archegonia being developed from separate superficial cells at the apex, and having long, multicellular, necks. About the time when they first appear the tip of the nucellus begins to break down, this disorganization proceeding downwards until there is (when the archegonia are mature) a broad circular pollen chamber open to the top of the prothallus, thus permitting the pollen grains to rest on the necks of the archegonia. The development of the pollen grain is closely similar to that of *Larix* and it is shed in the 5-nucleate condition. Division of the body cell occurs immediately after pollination and the pollen tube forces its way between the neck cells and discharges its contents into the egg within a few hours. The fusion nucleus divides three times to form eight nuclei, some of which then become organized into walled cells, very loosely connected into a proembryo. Each of these cells, after division of its nucleus, elongates and cuts off a small embryonal cell containing one of the two nuclei, the larger cell remaining, the suspensor, elongating rapidly to thrust the embryo cell deep into the prothallus tissue. The embryo cell divides to form an ovoid mass of cells of which those next to the suspensor elongate in succession giving rise to embryonal tubes which add to the length of the suspensor. The whole process is strongly reminiscent of what takes place in *Actinostrobus* among the conifers. This description applies more particularly to *Ephedra trifurca*, and it is uncertain how far the embryo development of other species agrees with it. In any case only one embryo matures.

Welwitschia.—*W. mirabilis* is the only species of this remarkable genus and is found in two isolated and restricted areas of the coastal desert region of Damaraland in South-west Africa. It is by far the most remarkable member of the Gnetales not only in its habit but also both in the form of its flowers and the details of its development. Knowledge of these details is largely due to investigations carried out by H. H. W. Pearson. An adult plant has somewhat the form of a gigantic radish two to four feet in diameter, projecting less than a foot above the ground, and terminating in a long tap-root below. The two strap-shaped leaves trail along the ground to a length of 10 ft. or more, and become split into a number of narrow thong-like strips. They retain the power of growth at the base throughout the life of the plant which probably exceeds 100 years. The characteristics of the plant accord well with the interesting suggestion that it may represent an "adult seedling." Numerous circular pits occur on the concentric ridges of the depressed and wrinkled crown, marking the positions of former inflorescences, new ridges subsequently appearing outside the old ones. The inflorescences have the form of dichasially branched stalks bearing the cones, from one to 20 in the female plant and up to 50 in the male. The female cone is about an inch long and scarlet in colour, the male smaller and more slender. Each consists of an axis bearing a large number of alternating pairs of overlapping bracts, in the axils of which are the flowers. The staminate flower (fig. 22) is enclosed by a perianth of two opposite pairs of bracts, surrounding a ring of six stamens united below but free above and each terminating in a trilobular anther. In the centre of the flower is an abortive ovule the integument of which projects upwards as a spirally

twisted tube with a stigma-like expansion at its apex. In the development of the pollen grain, a single prothallial nucleus is cut off, which disappears again about the time of pollination. There are only two further divisions resulting in a tube nucleus and two male nuclei, the formation of a stalk cell which occurs without exception in all conifers, as well as in *Ephedra*, being omitted. There is evidence that pollination is effected by insect agency. The ovulate flower consists of an erect ovule with two investments of which the outer is winged and represents the perianth, formed of a pair of completely connate bracts, the inner being the integument which has the usual long tubular micropyle (fig. 22). No pollen chamber is formed, but numerous pollen tubes grow downwards in the nucellar cap. The megaspore begins to develop as usual, becoming filled with protoplasm containing over 1,000 nuclei before walls appear. The latter divide the whole sac into multinucleate compartments, those in the micropylar end containing fewer and larger nuclei, any of which may function as eggs. The remainder contain about a dozen nuclei each, all of which fuse together in the compartment, thus forming a tissue of uninucleate cells which then grows considerably and may be termed the endosperm. The micropylar multinucleate cells put out long tubes which grow upwards into the nucellar cap, and into which the egg nuclei pass. These ascending prothallial tubes meet, and fuse with the descending pollen tubes and at the point of

FROM ENGLER & PRANTL, "DIE NATÜRLICHEN PFLANZENFAMILIEN" (WM. ENGLEMAN) FIG. 21.—MALE FLOWER OF EPHEDRA FRAGILIS

FROM H. H. W. PEARSON, IN THE PROCEEDINGS OF THE ROYAL SOCIETY FIG. 22.—WELWITSCHIA: CROSS-SECTION OF FLORAL STRUCTURES. A. MALE FLOWER; B. FEMALE FLOWER

fusion, fertilization occurs. The fertilized egg forms a wall and elongates into a tube from which an embryo tip cell is cut off, the remainder of the tube being the suspensor which carries the embryo deep into the endosperm. The further development is similar to that in *Ephedra*, including the formation of embryonal tubes from the young embryo.

Gnetum is represented by about 30 species, mostly climbers, found both in tropical America and in tropical regions of the Old World. The oval leaves are two or three inches long and are borne

in pairs at the swollen nodes. The cones are long and cylindrical and bear whorls of flowers at each node, accompanied by numerous sterile hairs, in the axils of cup-like concrescent bracts. In a male inflorescence very numerous flowers may be found, up to about 3,000 in one species, while in a female spike the number of flowers probably does not reach 100. The staminate flower consists of a perianth of two concrescent bracts enclosing a

nucleate "cells," the nuclei of each cell subsequently fusing so that an endosperm of uninucleate cells results, into which the developing embryos penetrate. Each zygote of *G. Gnemon* is stated to elongate and form a long tortuous multinucleate suspensor, from the lower end of which a small, also multinucleate, embryo cell is cut off. Walls are said to appear in this "cell" and so reduce it to a tissue of uninucleate cells. This account certainly does not apply to all species and requires confirmation.

In one or two species the lower half of the sac forms a firm endosperm tissue *before* fertilization, as first observed by J. P. Lotsy in 1899. The accuracy of this observation was questioned by J. M. Coulter in 1908, but it is probable that his preparations did not include the critical stages necessary for confirming or refuting Lotsy's statements, as the latter have since been shown by H. H. W. Pearson to be correct. Coulter described a remarkable development of nutritive tissue, which he named pavement tissue, below the embryo-sac (which is also seen in one or two conifers), and concluded that this had been mistaken by Lotsy for tissue *inside* the embryo-sac.

The later development of the embryo is similar to that of *Welwitschia*, and in both genera a rod-like outgrowth is formed from the hypocotyl at its junction with the radicle, which serves as a feeder and draws nourishment from the endosperm during the germination of the seed.

The climbing species of *Gnetum* are characterized by the production of several concentric cylinders of wood and bast from as many successively formed cambium cylinders produced in the pericycle, as in *Cycas*.

BIBLIOGRAPHY.—In the books listed below under the chief groups the reader will find the titles of hundreds of detailed papers on the Gymnosperms. None of these are quoted separately with the exception of a very few of special importance or historic interest or with an exceptionally full bibliography. *General:* E. Strasburger, *Die Coniferen und Gnetaceen* (Jena, 1872); *Die Angiospermen und die Gymnospermen* (Jena, 1879); A. B. Rendle, *The Classification of flowering plants*, vol. i. (Cambridge, 1904); J. P. Lotsy, *Vorträge über Botanische Stammesgeschichte*, band 2 and 3 (Jena, 1909 and 1911); J. M. Coulter and C. J. Chamberlain, *Morphology of Gymnosperms* (New York, 1925, but only reprinting the 1917 edition with bibliography to that date); P. Pilger, "Die Gymnospermen," in Engler's *Pflanzenfamilien* (1926). *Cycadales:* S. Ikeno, "Das Spermatozoid von *Cycas revoluta*," *Botanical Magazine, Tokyo*, vol. x. (1896); H. J. Webber, "Spermatogenesis and Fecundation of *Zamia*," *U.S. Department of Agriculture Bulletin* 2 (Washington, 1901); C. J. Chamberlain, *The Living Cycads* (University of Chicago Press, 1919); and a number of papers in the *Botanical Gazette* and elsewhere, where a bibliography can be found. *Ginkgoales:* S. Hirasé, "Etudes sur la fécondation, etc., de *Ginkgo biloba*," *Journal of the College of Science, Imperial University of Japan, Tokyo*, vol. xii. (1893); A. C. Seward and J. Gowan, "The Maidenhair Tree," *Ann. Bot.* (1900); H. L. Lyon, "The Embryogeny of *Ginkgo*," *Minnesota Botanical Studies*, vol. iii. (1904). *Coniferales:* W. Dallimore and Bruce Jackson, *A Handbook of Coniferae, including Ginkgoaceae* (London, 1923); A. C. Seward and S. O. Ford, "The Araucariaceae, recent and extinct," *Phil. Trans. R. Soc.*, (1906), with full bibliography; W. T. Saxton, "The Classification of Conifers," *New Phytologist*, vol. xii. (1913), with bibliography; A. A. Lawson, "The life history of *Pharosphaera*," and "The life history of *Microcachrys*," both in *Proc. Linn. Soc. of New South Wales* (1923). *Gnetales:* L. Hooker, "*Welwitschia mirabilis*," *Trans. Linn. Soc.* (London, 1864); F. O. Bower, "Germination, etc. of *Welwitschia*," *Quart. Journ. of Micr. Sci.* (1881); "Germination and Embryology of *Gnetum*," *ibid.*: (1882); J. P. Lotsy, "Contributions to the life history of *Gnetum*," *Annales du Jardin Botanique de Buitenzorg*, vol. xvi. (1899); W. J. G. Land, "*Ephedra trifurca*," *Botanical Gazette* (1904 and 1907); H. H. W. Pearson, "Some Observations on *Welwitschia*," and "Further observations on *Welwitschia*," *Phil. Trans. R. Soc.* (1906 and 1909). (W. T. SA.)

GYMPIE, a mining town of March county, Queensland, Australia, 107 m. N. of Brisbane, and 61 m. S. of Maryborough by rail. Pop. (1921) 8,769. Gympie became a municipality in 1880. Gold mines are worked in the district, which also abounds in copper, silver, antimony, cinnabar, bismuth and nickel.

GYNAECOLOGY, the name given to that branch of medicine which concerns the pathology and treatment of affections peculiar to the female sex.

Gynaecology is a very ancient branch of medicine. The papyrus of Ebers, one of the oldest known works on medicine (1550 B.C.), contains references to diseases of women, and it is recorded that specialism in this branch was known amongst Egyptian medical

AFTER LOTSY IN THE "ANNALES DU JARDIN BOTANIQUE DE BUITENZORG" (E. J. BRILL)
FIG. 23.—*GNETUM GNEMON*. A. LONGITUDINAL SECTION OF FEMALE FLOWER; B. PROTHALLUS AT TIME OF FERTILIZATION; C. PROTHALLUS AFTER FERTILIZATION

slender axis projecting above the perianth and terminating in two sporangia. The pollen appears to be formed in precisely the same manner as that of *Welwitschia*. Incomplete female flowers are often found in the male inflorescence containing ovules with one integument instead of two, but these rarely set seed. A perfect female flower (fig. 23) consists of an ovule with three investments of which the outer is generally regarded as a perianth of two concrescent bracts. Of the other two the inner arises first and develops the long slender micropylar tube characteristic of all Gnetales and is followed by a much shorter outer covering, the outer integument. Several megaspores may begin to develop in a young ovule, but only one attains full size. In all species the embryo-sac, as in *Welwitschia*, becomes filled with numerous free nuclei, and in some species, probably in the large majority, fertilization occurs at this stage, the contents of pollen tubes being discharged into the embryo-sac, any of the nuclei near the micropylar end apparently functioning as eggs. The lower half of the sac then becomes partitioned (as in *Welwitschia*) into multi-

practitioners. The Vedas contain a list of therapeutic agents used in the treatment of gynaecological diseases. The treatises on gynaecology formerly attributed to Hippocrates (460 B.C.) are now said to be spurious, but the wording of the famous oath shows that he was at least familiar with the use of gynaecological instruments. Writers of the Graeco-Roman period of medicine who have treated of this branch are Celsus (50 B.C.-A.D. 7), Soranus of Ephesus (A.D. 98-138) and Galen (A.D. 131-201), who devotes the sixth chapter of his work *De locis affectis* to gynaecological ailments. It is evident that during this period much of the gynaecological work was in the hands of female healers. Martial refers to these "*feminae medicae*" in his epigram on Leda. These women must not be confounded with the midwives, who are always described as "*obstetrices*." Throughout the Byzantine and Mediaeval periods of medicine, which comprise a period of more than a thousand years, gynaecology shared in the general sterility and even decadence which accompanied medical and all other branches of scientific learning; writers on gynaecology, like Oribasius (A.D. 325-403), were mere compilers of the work of their predecessors and practice was bound by ancient authority and tradition. The growth of interest in diseases of women during the Renaissance period (A.D. 1453-1600) is shown in the huge "Gynecia" or encyclopedia of gynaecology issued by Caspar Wolf of Zürich in 1566. In the seventeenth century what has been described as the first work on operative gynaecology in the modern sense was written by Hendrik van Roonhugze (1625?); it contains case reports on extra-uterine pregnancy and rupture of the uterus and the description of a scientific operation for vesico-vaginal fistula. Amongst contributions to gynaecology in the eighteenth century are William Hunter's proposal for excision of ovarian cyst and his description of retroversion of the uterus, Robert Houston's treatment of ovarian cysts by tapping, Matthew Baillie's description of dermoid cysts of the ovary and Joseph Recamier's invention of special specula.

Operative gynaecology, as an independent speciality, had no real existence until the first half of the nineteenth century and its founders may be said to be Ephraim MacDowell (1771-1830) of Virginia and John Marion Sims (1813-1883) of South Carolina. MacDowell performed his first ovariectomy (removal of an ovarian cyst by abdominal section) in 1809. Sims was a great surgical genius whose fame quickly spread over the whole civilized world because of his success in curing the hitherto incurable condition of vesico-vaginal fistula. In British surgery, ovariectomy became firmly established by the work of Charles Clay (1801-1893) of Manchester and Sir Spencer Wells (1818-1897) of London. Other prominent British gynaecologists of this period were Sir James J. Simpson (1811-1870) of Edinburgh, who invented the uterine sound, and Lawson Tait (1845-1899) of Birmingham, who was the pioneer in operations on the Fallopian tubes, performed the first deliberate operation for ruptured extra-uterine pregnancy, and insisted on asepsis as distinguished from antiseptics in gynaecological operations.

Menstruation (q.v.).—At puberty, which in northern folk arrives at the age of from 13 to 15 years, the uterus and ovaries begin to undergo a complex and correlated series of changes which recur in monthly cycles and constitute the function of menstruation. Menstruation continues throughout the whole reproductive period of a woman's life, is arrested only by pregnancy, and ends at the time of the menopause, commonly known as the "change of life" (usually between 45 and 50 years of age). The double purpose of menstruation is to liberate an ovum (egg) from the ovary and to prepare the endometrium (the mucous membrane lining the uterine cavity) for the reception of such ovum should fertilization occur. The cycle of change which occurs in the ovary is known as *ovulation*, and that which occurs in the endometrium is chiefly concerned with the formation of the *menstrual decidua*. If fertilization occurs, the ovum becomes embedded in the prepared endometrium, where it continues to develop into a child, and further menstruation is arrested. If, on the other hand, fertilization does not occur, the menstrual decidua in due course becomes cast off and what is known as the *menstrual flow* occurs, after which the cycle of changes in the uterus and

ovaries is repeated. The menstrual flow is the outward and visible sign of menstruation; it recurs, in the absence of pregnancy, about every 28 days, lasts about 5 days, and consists of a discharge from the uterus of 4 to 6 ounces of blood mixed with fragments of menstrual decidua and with mucus from the glands of the cervix. The cycle of change which occurs in the endometrium may thus be said to consist of alternate phases of building up and breaking down. During the building up phase, which occupies about 14 days, the menstrual decidua is formed by a gradual increase in thickness of the endometrium; this is followed by the menstrual flow or breaking down phase, and the cycle is completed by a phase of rest and repair. The stimulus to the uterine cycle is provided by ovulation, for if the ovaries be removed the endometrium remains permanently in the resting phase. During ovulation an ovarian follicle (egg-chamber) ripens and ruptures, liberating an ovum; at the site of rupture a temporary yellow body (*corpus luteum*) forms, and recent work has shown that the internal secretion of this body provides the chemical stimulus to the uterine changes. The time relationship between the events in the ovarian and uterine cycles is as follows: the ovarian follicle ruptures about 14 days before the onset of the menstrual flow, reaches its full development about 7 days before the flow and begins to decline after the flow has begun. There is very little evidence for the belief that the right and left ovaries ovulate alternately.

Common Disorders.—These are: (1) amenorrhoea (absence of flow), (2) menorrhagia (excessive flow), (3) epimenorrhoea (too frequent flow), (4) irregular and scanty flow, (5) dysmenorrhoea (painful flow). Amenorrhoea may arise from physiological causes, such as pregnancy, lactation, the menopause. The onset of the first menstrual flow may be delayed beyond the usual age, but if menstruation is delayed beyond the age of 17 or 18 medical advice should be sought, as there may be some developmental error in the uterus or vagina and the sooner this is discovered the better. Amenorrhoea of pathological origin may be due to error in growth or development of the reproductive organs, or to constitutional disease. Under developmental errors come those cases where menstruation occurs but the escape of menstrual fluid is prevented by the presence of a membrane obstructing the vaginal orifice (so called "imperforate hymen") or even by the absence of the vagina or by imperforation of the cervix uteri—"concealed menstruation". The blood accumulates in the vagina or uterus, or both, and forms a swelling which gradually becomes larger. The uterus may fail to develop beyond the infantile state or may be completely absent, and in the latter case the amenorrhoea is permanent. Amongst constitutional causes may be mentioned chlorosis, secondary anaemia, tuberculosis, mental shock and strain, acute illness, and defective function of the thyroid or pituitary glands; in most of these the amenorrhoea is usually temporary. The treatment of amenorrhoea depends on the cause; in case of temporary amenorrhoea due to constitutional causes the flow can often be re-established by measures directed to improve the general health. It should be noted that menstruation (*i.e.*, ovulation and the formation of menstrual decidua) may occur with absence of menstrual flow, otherwise it is not possible to account for the occurrence of pregnancy during a period of amenorrhoea—a not uncommon event during the amenorrhoea of lactation.

Menorrhagia signifies excessive bleeding at the time of the menstrual flow, but no irregular bleeding during the interval between the flows. Amongst local causes are fibromyomata of the uterus, uterine polypi, excessive thickness of the endometrium, fibrosis and chronic subinvolution of the uterus, inflammation of the Fallopian tubes; amongst the many general causes are (a) diseases associated with plethora, such as chronic cardio-vascular disease, chronic renal disease (b) primary blood diseases, such as pernicious anaemia, leukaemia, purpura and haemophilia, (c) endocrinous diseases, especially hypo- and hyper-thyroidism (d) at puberty and again at the menopause there may be, for a time, excessive menstrual haemorrhage; but women should be warned that medical advice should be sought for haemorrhage at the time of the menopause as there may be a new growth of the uterus.

Irregular haemorrhage independent of menstruation is always symptomatic of uterine disease, and when occurring after the age of 30. and especially after the menopause, is often significant of cancer of the uterus. Irregular haemorrhage during early pregnancy means either threatened abortion or extra-uterine gestation. The treatment of any form of haemorrhage from the uterus depends on the cause and demands careful diagnosis. Amongst drugs which relieve certain forms of haemorrhage are ergot, pituitary extract, ovarian extract, calcium salts and parathyroid gland. The treatment of new growths and other local conditions is considered under the appropriate sections.

Too frequent or irregular menstruation is not uncommon and, so long as the flow is not profuse, has no particular significance; since the ovary is the pacemaker of the uterus in menstruation, the cause probably lies in irregular ovulation or other disturbed function of the ovary.

There are two varieties of menstrual pain or *dysmenorrhoea* (a) spasmodic (b) congestive. *Spasmodic dysmenorrhoea* is due to painful contractions of the uterus and the pain is severe and cramplike, beginning with the onset of the flow and lasting a few hours or a day; the pain is believed to be associated with the shedding of the menstrual decidua and the entire membrane can often be discovered in the discharge. In a few cases the uterus is poorly developed, but usually no abnormality can be detected. The treatment consists of rest, hot baths, and such anti-spasmodic drugs as phenazone, phenacetin, aspirin, atropine. If this fails the little operation of dilatation of the cervix often cures. Cases which arise in later life are usually due to a submucous fibromyoma of the uterus; the treatment consists in removal of the tumour. Congestive dysmenorrhoea is a severe aching which begins about a week before, and is relieved by, the flow; it is due to chronic inflammatory disease of the Fallopian tubes or of the uterus, or to uterine fibromyomata. The treatment consists in the surgical removal of the cause.

Infections of the Reproductive Organs.—About sixty per cent of infections are puerperal (after childbirth or abortion), about twenty per cent are gonorrhoeal, and the remainder are fortuitous infections, often secondary to a primary focus elsewhere, such as in the bowel (appendicitis, diverticulitis), the tonsils or the teeth; about five per cent of infections are due to the tubercle bacillus. In most puerperal infections, and in all gonorrhoeal, the infection is *ascending*, i.e., the infection begins in the vulva, vagina, or cervix uteri and ascends upwards to the uterus, Fallopian tubes and peritoneum. In other cases the bacteria are carried to the organs by the blood-stream (*haematogenous* infection). The infection may remain localized to the various organs, or the bacteria may gain the blood-stream in which they may multiply and cause the very grave condition known as septicaemia. (See SEPSIS.) The infective diseases which may be caused are vulvitis, vaginitis, cervicitis, endometritis, salpingitis, ovaritis and peritonitis; usually, especially in puerperal and gonorrhoeal infections, the condition is widespread. Syphilitic infection of the reproductive organs is considered elsewhere. (See VENEREAL DISEASES.)

Diseases of the External Genital Organs.—The vulva comprises several structures grouped together for convenience of description. (See REPRODUCTIVE SYSTEM.) The affections to which these structures are liable may be classified as follows: (1) Injuries, either occurring during parturition or accidental; the commonest is rupture of the perineum, (2) Inflammation of the vulva or *vulvitis*. Simple vulvitis is due to want of cleanliness or to irritating discharges and in children may result from threadworms. Severe infective vulvitis is usually due to gonorrhoea. The symptoms of vulvitis are heat, itching and throbbing, and the parts are red and swollen and bathed with discharge. In the gonorrhoeal variety the local inflammation is very severe, the discharge profuse and purulent and there is scalding pain on micturition. The treatment of simple vulvitis is rest in bed, cleanliness and bathing the vulva with warm antiseptic lotions. Gonorrhoeal vulvitis is almost invariably associated with infection of the urethra, vagina and cervix; the treatment, which is prolonged and requires an expert, consists chiefly in the precise application of a

special antiseptic, such as two per cent acriflavine, to the above mentioned sites of infection. For obvious reasons, a complete cure must be obtained, and the infection must be prevented from spreading to the Fallopian tubes. (3) The vulva may become the seat of various cutaneous diseases the most important of which are eczema, erythema, herpes, furunculosis, tubercle, elephantiasis, leucoplakia and kraurosis. These diseases present the same characters as in other parts of the body. In leucoplakia the surface of the vulva becomes thickened and covered with white patches, and later cracks and ulcers appear; the disease is important because, if neglected, it is often the forerunner of cancer. (4) Tumours of the vulva, cysts of Bartholin's gland and vascular *caruncles* of the urethral orifice are the commonest. Any part of the vulva may be the seat of new growths, simple or malignant. *Pruritus* of the vulva is the name given to persistent itching of this part; it is a symptom more than a disease, and accompanies vulvitis and most of the conditions given under (4) above. It is a frequent accompaniment of diabetes and may be an early symptom of cancer; for these reasons it should not be disregarded.

Diseases of the Vagina.—The vaginal walls are kept moist by a thin opalescent fluid containing desquamated epithelium and cervical mucus; its acid reaction is due to the vaginal bacilli. When the vaginal secretion is excessive it is called *leucorrhoea* or "the whites." (1) Malformations. The vagina may be absent in whole or in part or may present a longitudinal septum. Occlusion of the lower end by a membrane prevents the escape of the menstrual flow and leads to the gradual distension of the vagina with blood ("haematocolpos"). (2) Prolapse of the vagina is a hernial protrusion of the pelvic contents through the opening in the pelvic floor muscles, the vaginal walls forming the covering of the protrusion; there is usually concomitant prolapse of the uterus ("utero-vaginal prolapse"). Protrusion of the anterior wall by herniation of the bladder is called *cystocele*, and protrusion of the posterior wall by the rectum is called *rectocele*. Vaginal prolapse can be permanently cured by an operation; the palliative treatment is by vaginal pessaries. (3) Fistulae may form between the vagina and bladder, or vagina and rectum; they are usually the result of parturition and require closure by operation. Fistulae may also form in the late stages of carcinoma of the cervix uteri. (4) *Vaginitis*. (a) Simple catarrhal vaginitis is due to the same causes as simple vulvitis; occasionally in children it is important from a medico-legal aspect. (b) In gonorrhoea the vagina is infected together with the vulva and cervix; the vaginal walls are intensely red and covered with profuse yellow discharge. The treatment is the treatment of gonorrhoea. (c) Chronic vaginitis may follow the acute variety and may persist for a long time. The vagina is rarely the seat of tumours, but cysts are not uncommon.

DISEASES OF THE UTERUS

The uterus is functionally a very active organ; at puberty it grows into the pear shape characteristic of sexual maturity, at the menopause it shares in the general atrophy of the reproductive organs, during each menstruation its lining membrane undergoes great modification, during pregnancy it undergoes remarkable growth, and during the puerperium it undergoes an even more remarkable process of "involution." It is subject to many disorders: (1) *Errors in growth and development*. The uterus may be congenitally absent, may remain in the infantile state (*uterus foetalis*), or may fail to reach full maturity (*uterus pubescens*); these conditions cause such abnormalities in the menstrual and reproductive functions as amenorrhoea, scanty menstruation, dysmenorrhoea or sterility. The uterus may be completely or partially double (*uterus didelphys*, *uterus bicornis*). (2) *Displacements*. Normally the uterus is bent forwards (anteversion) and turned forwards (anteflexion). The chief displacements of the uterus are prolapse (downward displacement, popularly referred to as "falling of the womb") and retroflexion (backward bending). Prolapse is really a protrusion or hernia of the uterus through the opening between the muscles of the pelvic floor; the uterus is protruded along, and ultimately through, the vaginal canal and there is usually an associated prolapse of the vaginal walls (*q.v.*). In the early stage of prolapse the uterus remains

within the vagina; in the late stage the cervix lies outside the vulva and the vagina is completely inverted (complete prolapse or procidentia). The symptoms are a "bearing down" feeling, great discomfort and fatigue in walking and interference with micturition and defaecation. Prolapse is very rarely met with in women who have not borne children, and its eventual cause is the stretching and injury of the fasciae and muscles of the pelvic floor accompanying parturition; an inborn tendency doubtless exists in many women, but in some cases too hasty delivery of the child by midwifery forceps is blamable. The palliative treatment is by vaginal pessaries; but cure by operation is far preferable to the permanent wearing of these uncleanly devices. The modern operation, which consists of a plastic repair of the pelvic floor, vaginal vault and perineum, gives the maximum of success with the minimum of risk. Retroflexion of the uterus (bending backwards) is always combined with retroversion (rotation backwards through a transverse axis); it may exceptionally occur as a congenital abnormality, but is nearly always acquired as the result of childbirth or abortion, or of inflammation of the Fallopian tubes. There is a great difference of opinion amongst gynaecologists as to the symptoms and effects of retroflexion, and as to the indications and methods of treatment. So long as the displaced uterus is healthy and is not fixed by adhesions it is, with the occasional exceptions of dyspareunia and sterility, symptomless and harmless, and requires no treatment. But when, as is sometimes the case, the uterus is in a state of chronic inflammation or subinvolution (*q.v.*), and is fixed by adhesions, it requires treatment for the relief of such symptoms as painful and profuse menstrual flow, dyspareunia, sterility or repeated abortions. Palliative treatment is by replacement and the insertion of a pessary, which is only possible when the uterus is not fixed. Curative treatment is by the operation of ventral suspension, which consists in suspending the body of the uterus or its ligaments to the anterior abdominal wall.

Inversion occurs when the uterus is turned inside out. It is only possible when the cavity is dilated, either after pregnancy or by a tumour. The greater number of cases are acute and follow immediately on delivery; acute inversion is accompanied by much shock and haemorrhage and has a very high mortality. Chronic inversion either results from the acute variety in untreated patients who have survived, or is due to the traction of a fundal intro-uterine tumour (usually a fibroid polypus). The symptoms of chronic inversion are haemorrhage and bladder troubles, and on examination a tumour is found in the vagina. Reduction of the condition is often difficult, particularly when it has lasted for a long time.

(3). *Inflammations, Acute and Chronic.*—These may be divided into inflammations of the cervix and inflammations of the body of the uterus, both of which may be acute or chronic. The majority of cases are due to puerperal infection or to gonorrhoea. A secondary infection by the bloodstream, especially from the streptococcus, may occur from a primary focus elsewhere. Pessaries in the vagina may cause infection, especially if not kept clean by douching and removed at intervals. Chronic inflammation of the cervix (cervicitis) is predisposed to by unhealed tears resulting from labour; it is commonly associated with what is known as an *erosion*, which is a red congested annular patch of mucous membrane. The symptoms of chronic cervicitis are a muco-purulent discharge. In acute cervicitis the cervix is red and swollen and a discharge of pus, in which the infecting germ may be discovered, pours from the cervical canal. The dangers are upward spread of the infection to the uterus, Fallopian tubes and peritoneum. The treatment of acute infections is rest in bed, vaginal douches and the application of strong antiseptics to the cervical canal. Chronic infections may be cured by the direct application of antiseptics; in cases associated with unhealed tears and erosion, a cure may be effected by excision of the diseased portion. Inflammation of the body of the uterus affects chiefly the lining membrane or endometrium and is known as *endometritis*. Acute endometritis is usually the result of puerperal or of gonorrhoeal infection. Acute puerperal endometritis is a very serious condition, due usually to infection with the streptococcus; the infection is very liable

to spread to the tubes (acute salpingitis), peritoneum (acute peritonitis) or blood stream (septicaemia). Gonorrhoeal endometritis is always secondary to infection of the cervix; it is serious in so far as infection of the Fallopian tubes may follow. Chronic endometritis may be interstitial or glandular and results from bacterial infection. The chief types of interstitial endometritis are senile and tuberculous. Senile endometritis affects women after the menopause and causes a foul-smelling discharge, sometimes blood-stained. In such cases cancer of the body of the uterus must be excluded for the symptoms of the two conditions are closely similar. If the discharge cannot escape the uterus becomes distended with pus, forming a *pyometra*. Tuberculous endometritis is extremely rare and is usually due to spread from the tubes. Chronic glandular endometritis is characterized by very great thickening of the endometrium due to proliferation of the glands; the symptom is profuse menorrhagia, and relief can be obtained only by the operation of curetting. Inflammation of the whole uterus, muscular wall as well as endometrium, is known as *metritis*. Acute metritis is nearly always the result of puerperal infection and the symptoms and complications are similar to those of acute endometritis. Chronic metritis is the sequel to the acute variety; the uterus is enlarged and fibrous, and the chief symptom is menorrhagia about the time of the menopause. The menorrhagia in this case cannot be cured by curetting, because the endometrium is not thickened; the intra-uterine application of radium, however, acts like a charm possibly by causing an artificial menopause.

(4). *New Growths of the Uterus.*—The uterus is the commonest seat of new growths. (*See Tumours.*) The innocent new growths comprise adenoma, fibromyoma, adenomyoma and polypi of various kinds; the malignant are carcinoma, sarcoma and chorionepithelioma. Adenomata usually assume a polypoid form, and occur both in the body and cervix; their symptom is uterine haemorrhage and their treatment is surgical. Fibromyomata or "fibroids" are extremely common tumours, occurring especially in women between the ages of 35 and 50. They are believed to occur in about 25% of women over 35 years of age, but, happily, in the great majority of cases they are small and cause no symptoms. It is doubtful if they ever originate after the menopause. They are solid round or ovoid tumours, composed of a mixture of fibrous and muscular tissue, and are usually multiple. They begin as small seedlings in the wall of the uterus and may grow to an enormous size. According to the position which they occupy in the uterine wall they are divided into intramural, subperitoneal and submucous. The two latter may assume a polypoid form. Submucous fibroids and, to a less extent, intramural fibroids give rise to severe menorrhagia, and, if this is allowed to persist, the patient may get into a dangerous state of anaemia. At the menopause they share in the general atrophy of the uterus, and may almost disappear. Secondary changes are common in fibromyomata, and include mucoid degeneration, cyst-formation, fatty changes, necrobiosis ("red degeneration"), septic infection (sloughing fibroid), and sarcomatous change.

The modes in which fibroids imperil life are haemorrhage (the commonest of all), septic infection, which is one of the most dangerous, impaction in the pelvis, twisting of the pedicle by rotation and intestinal and urethral obstruction. During pregnancy they share in the growth of the uterus and increase greatly in size; but interference with pregnancy, such as abortion, is common. If growing from the cervix or lower part of the uterus they may obstruct labour and necessitate Caesarean Section (*q.v.*). Small symptomless fibromyomata, often discovered by accident, require no treatment, but should be watched. Fibromyomata of a certain size, or causing symptoms, require surgical treatment, which will be either hysterectomy (removal of the uterus) or myomectomy (removing the tumour and leaving the uterus). Hysterectomy is the easier and usually the safer operation; myomectomy is preferable when the patient is young and it is desired to preserve the function of childbearing. Treatment by drugs or by electrical currents is, rightly, a thing of the past, but X-rays and radium have an important place. The insertion of radium into the uterus is the ideal treatment for menorrhagia due to

small submucous fibroids, but is not suitable for tumours of any size. Haemorrhage from fibroids often ceases after several applications of X-rays; but this treatment is too uncertain in its action to compete with surgery except in cases in which an operation is for other reasons contraindicated.

(5). *Malignant Disease of the Uterus.*—The varieties of malignant disease met with in the uterus are carcinoma, sarcoma and chorionepithelioma malignum. The age at which women are most subject to carcinoma of the uterus is towards the decline of sexual life. Of 3,385 collected cases of cancer of the uterus 1,169 occurred between 40 and 50, and 856 between 50 and 60. In contradistinction to fibroid tumours it frequently arises after the menopause. It may be divided into cancer of the body and cancer of the neck (cervix). Cancer of the neck of the uterus is almost exclusively confined to women who have been pregnant. Predisposing causes are tears of the cervix, erosion and chronic cervicitis. The symptoms which induce women to seek medical aid are haemorrhage, foetid discharge, and, later, pain and cachexia. An unfortunate belief amongst the public that the menopause is associated with irregular bleeding and offensive discharges has prevented many women from seeking medical advice until too late. It cannot be too widely known that cancer of the cervix is in its early stages a purely local disease, usually curable by an operation or by radium. So important is the recognition of this fact in the saving of life that the council of the British Medical Association published in 1909 in British and Colonial medical and nursing journals a special appeal to medical practitioners, midwives and nurses. It will be useful to quote here a part of the appeal directed to midwives and nurses: "Cancer may occur at any age and in a woman who looks quite well and who may have no pain, no wasting, no foul discharge and no profuse bleeding. To wait for pain, wasting, foul discharge or profuse bleeding is to throw away the chance of successful treatment. The early symptoms of cancer of the womb are:—(1) bleeding which occurs after the change of life, (2) bleeding after sexual intercourse or after a vaginal douche, (3) bleeding slight or abundant, even in young women, if occurring between the usual monthly periods, and especially when accompanied by a bad-smelling or watery blood-tinged discharge, (4) thin watery discharge occurring at any age." On examination the cervix presents certain characteristic signs to touch and sight: hard nodules or definite loss of substance, extreme friability and bleeding after slight manipulation. Cancer of the cervix may assume a proliferating type, forming the well known "cauliflower" excrescence. In the early stages, before the disease has spread to the surrounding tissues, cancer of the cervix is curable by operation. The modern operation is that perfected by the late Professor Wertheim of Vienna, and consists in removal of the whole uterus, upper third of the vagina and as much of the surrounding tissues as possible. The operation is a severe one with a primary mortality of about ten per cent, but thirty to forty per cent of early cases may be expected to remain free from recurrence for five years or more. Treatment of early or "operable" cases of cancer of the cervix by radium gives better results than operation. The latest statistics, such as those published by Heyman, of the Stockholm Radium Institute, show that about fifty per cent of early cases may be expected to remain free from recurrence for five years or more. Radium treatment demands much skill and experience in order to give such good results. A very great advantage of radium treatment is that the primary mortality is about one per cent compared with the ten per cent or more associated with operative treatment. In advanced cases treatment by radium and X-rays must be relied upon to palliate, if not to cure. Cancer of the body of the uterus is rare before the forty-fifth year and is most frequent after the menopause. The majority of the patients are nulliparae. The signs are fitful haemorrhages after the menopause and an offensive discharge which is usually, but not always, blood-stained; the uterus is usually somewhat enlarged. Removal of the uterus (hysterectomy) is the only treatment. Chorion epithelioma or chorionic cancer is a malignant disease with microscopic characters resembling the cells of the chorionic epithelium. It occurs in connection with recent pregnancy and particularly with the variety of abortion termed hydatidiform mole. It quickly

ulcerates and infiltrates the uterine tissues, forming metastases with a rapidity unequalled by any other type of growth. Clinically it is recognized by the occurrence after pregnancy of violent haemorrhages and progressive cachexia. The growth is usually primary in the uterus but may be so in the Fallopian tubes or in the vagina. A few cases have been recorded unconnected with pregnancy. Immediate and wide removal of the affected organ is the only treatment. Sarcoma of the uterus may occur in the body and in the cervix. It occurs at an earlier age than carcinoma. It may originate either in the wall or endometrium of the healthy uterus, or as a secondary change in a fibromyoma of the uterus. Uterine enlargement and haemorrhage are the symptoms. The differential diagnosis is microscopic. Extirpation of the uterus is the only chance of prolonging life.

Diseases of the Fallopian Tubes.—The Fallopian tubes or oviducts are liable to septic infection (acute and chronic *salpingitis*), tuberculosis, innocent and malignant new growths, and tubal pregnancy. Salpingitis is nearly always secondary to septic infection of the genital tract. The chief causes are septic endometritis following labour or abortion, gonorrhoea, infected fibromyoma, and cancer of the uterus. The right tube may be infected by appendicitis. In some cases the infection of the tubes appears to be accidental, probably the result of an infective focus elsewhere, such as the tonsils or respiratory tract. When the pus escapes from the tubes into the peritoneal cavity it causes local or general peritonitis. Even mild cases of salpingitis result in gluing together of the fimbriae and sealing of the ostium (the abdominal opening or mouth of the tube), and matting together of the tube and ovary by peritoneal adhesions. If the inflammation continues after the ostium is sealed, pus accumulates in the tube forming a tubal abscess or *pyosalpinx*; if the tube becomes distended with serous fluid it is termed a *hydrosalpinx*. Distension of the tube with blood is termed a *haematosalpinx* and is nearly always due to tubal pregnancy. Acute salpingitis is a very severe illness, and is accompanied by high temperature, abdominal pain and tenderness, and much constitutional disturbance. The symptoms may become merged in those of general peritonitis. In chronic salpingitis there is a history of puerperal infection or gonorrhoea, followed by chronic pelvic pain, profuse menstruation and sterility; on examination the enlarged tubes may be felt. Acute salpingitis requires rest in bed in a propped-up posture (Fowler's posture), sedatives, hot fomentations and skilled nursing. Urgent symptoms and signs of spreading peritonitis may call for operation, chiefly for the purpose of peritoneal drainage. A pyosalpinx renders a woman an invalid and permanent relief can only be afforded by surgery. Tuberculous salpingitis is usually secondary to tuberculous infection in other parts, such as the lungs or peritoneum. The Fallopian tubes may be the seat of malignant disease; this is rarely primary but usually an extension of cancer of the uterus or ovaries. In *tubal pregnancy* the fertilized ovum becomes embedded in the tube instead of in the uterus. It is believed that fertilization occurs normally in the tube, and that the ovum does not reach the embedding stage until it has arrived in the uterus. If the passage of the ovum down the tube is delayed it becomes embedded in the tube. The chief cause of such delay is kinking and adhesion of the tube as the result of former salpingitis, and this state of the tube is found in seventy-five per cent of cases of tubal pregnancy. The tubal ovum has a precarious existence, because of the eroding action of the chorionic villi on the thin tubal wall. One of two events soon occurs: either the ovum becomes separated and surrounded by blood, and in consequence dies, forming a *tubal mole*; or, the eroding villi completely perforate the tubal wall, resulting in rupture of the tube and profuse intraperitoneal haemorrhage. After the formation of a tubal mole the tube undergoes spasmodic contractions and attempts to expel it through the abdominal ostium; this process, known as *tubal abortion*, is accompanied by violent attacks of pain and the escape of blood into the pelvic cavity. The blood is localized by adhesions and forms beside the tube a swelling of varying size known as a *pelvic haematocoele*. Tubal pregnancy usually comes to an end by mole formation or rupture at about the sixth week. In rare cases the ovum continues to develop after rupture of the tube and may even continue to

full-term, the placenta gaining attachment to the pelvic or abdominal structures. The uterus in tubal pregnancy undergoes slight enlargement and always develops a decidua which is expelled when the pregnancy is disturbed. The signs of tubal pregnancy before rupture are amenorrhoea, pelvic pain and the presence of an enlarged tube. When rupture occurs there is sudden and severe pain with great shock and collapse; the haemorrhage is usually so severe as to imperil life. The more common event is, fortunately, mole formation with tubal abortion and the formation of a haematocele; the symptoms of this are spasmodic attacks of severe pain and irregular uterine haemorrhage and, sometimes, the passage of a decidual cast from the uterus; on examination the haematocele is felt as a swelling in the pelvis. In all forms of tubal pregnancy the only treatment is abdominal section and removal of the affected tube; in rupture immediate operation is the only means of saving life. In those rare cases in which the placenta and foetus continue to develop until term, the child may be removed alive by abdominal section, but is often deformed and rarely survives for long.

Diseases of the Ovaries and Parovarium.—The changes which the ovaries undergo at puberty have already been described (see Menstruation); at the menopause they cease to function and undergo gradual atrophy. Congenital absence of the ovaries, except in association with some foetal monstrosity, is unknown. Prolapse of the ovary, a descent from its usual position into the pouch of Douglas, is usually associated with backward displacement of the uterus or with salpingitis and pyosalpinx, but it may occur independently from elongation of the utero-ovarian ligament. A prolapsed ovary is tender and painful and is one cause of dyspareunia (painful sexual intercourse). Inflammation of the ovary (oöphoritis) is (apart from tuberculous infection) seldom, if ever, primary, but is secondary to infection of the tubes or peritoneum, or, on the right side, to appendicitis. The causes of oöphoritis are therefore the same as those of salpingitis. An ovarian abscess may form and may reach a large size. Chronic oöphoritis may follow the acute form; the capsule is thickened and the follicles cannot rupture, and the ovary becomes converted into a collection of tiny follicular cysts. This state is sometimes referred to as the "small cystic ovary" or the "cirrhotic ovary." The ovary is frequently the seat of cystic and solid tumours. Cystic tumours are far the commoner and are of several varieties. The two commonest are the *pseudomucinous adenomatous cyst* which is multilocular, may arise at almost any age and may attain an enormous size, and the *epoöphoric cyst*, which is unilocular and arises from the tubules in the hilum of the ovary; both are innocent and both are occasionally bilateral. The so-called *dermoid cyst*, really a teratoma, which may contain bone, teeth, hairs, sebaceous material, skin and many other tissues, is also common. The *papillomatous cyst* may be semi-malignant and often gives rise to secondary implantations on the peritoneum; it is usually bilateral. *Broad ligament cysts* are unilocular and may reach a large size; they originate from the rudimentary Wolffian tubules. *Fibroma* is the commonest innocent solid tumour. Malignant disease (carcinoma and sarcoma) is fairly frequent; carcinoma of the ovary may be primary, or, more commonly, secondary to cancer of the gastro-intestinal tract or breast. "Chocolate" or "tarry cysts" of the ovary arise from implanted endometrium ("*endometrioma*"); they are usually bilateral and are associated with dysmenorrhoea and sterility. Ovarian cysts seldom cause pronounced symptoms, but are liable to such grave complications as torsion of the pedicle, rupture and suppuration; they are all liable to undergo malignant change. The treatment of all varieties of ovarian tumour is removal as soon as possible.

Diseases of the Pelvic Peritoneum and Connective Tissue.

—Women are peculiarly liable to peritoneal infections owing to the fact that the genital tract is in direct communication with the peritoneal cavity through the abdominal ostia of the Fallopian tubes. Consequently, any infection of the genital tract, by travelling upwards to the tubes may cause peritonitis. Nearly all these infections are the result either of childbirth and abortion or of gonorrhoea. Fortunately, the pelvic peritoneum has considerable powers of resistance, and nearly all peritoneal infections of genital origin become localized to the pelvic part of the peritoneal cavity. Pelvic peritonitis or perimetritis may proceed to abscess formation

the most common situation for these pus-collections being in the pouch of Douglas; from thence they either burst into the rectum or bladder or are, more fortunately, evacuated by operation. Even if pelvic peritonitis resolves without abscess-formation it always leaves adhesions between the uterus, tubes, ovaries and the adjacent coils of intestine, resulting in abnormal position of the pelvic organs, sterility, dysmenorrhoea and other pelvic pain. General peritonitis of genital origin is comparatively rare; it may follow puerperal infection, but seldom, if ever, is the result of gonorrhoea. *Hydroperitoneum*, a collection of free fluid in the peritoneal cavity, may be due to many general causes but also to papillomatous or cancerous ovarian tumours. *Pelvic cellulitis* or *parametritis*, a septic inflammation of the pelvic cellular tissue, chiefly at the bases of the broad ligaments, is usually the result of puerperal infection; the bacteria gain entrance to the cellular tissue through tears of the cervix uteri, such as are liable to result from difficult or instrumental labour. The symptoms are chill, rise of pulse-rate and temperature, and intrapelvic pain. On examination, there is tenderness and swelling on one or both sides of the pelvis beside the uterus, and the uterus becomes fixed and immovable in the exudate as if embedded in plaster of Paris. The inflammation may undergo resolution if appropriately treated or may go on to suppuration, forming an extra-peritoneal abscess which may point in the vagina, rectum or bladder and occasionally in the groin. If the pus can be localized an incision should be made and the abscess drained.

Crossen, *Diseases of Women* (1927). (E. L. H.)

GYNANDROMORPH, a term used in biology to denote an intersex of the mosaic type, *i.e.*, one side or part of the body is male, the other female. A gynandromorph is to be distinguished from an hermaphrodite (*q.v.*) in which the entire animal is intermediate between male and female. Gynandromorphs occur in several groups of animals, notably in insects and birds, but not in mammals. (See SEX.)

GYÖNGYÖS, a city of Hungary, situated at the foot of the Mátra mountains in the county of Heves. Population (1920) 19,714. The Gyöngyös river, rising in the Mátra mountains, flows by the city and thence south-east to join the Tarna, a subaffluent of the Danube. There are several churches, a large Franciscan college, hospital and gymnasium. Near by is the open air sanatorium of Bene.

GYÖNGYÖSI, ISTVÁN [STEPHEN] (1620–1704), Hungarian poet, was born of poor but noble parents in the county of Gömör, Hungary. His abilities early attracted the notice of Count Ferencz Wesselényi, who in 1640 appointed him to a post of confidence in Fülek castle. Here he remained until 1653, when he married and became an assessor of the judicial board. In 1681 he was elected as a representative of his county at the diet held at Soprony (Oedenburg). From 1686 to 1693, and again from 1700 to his death in 1704, he was deputy lord-lieutenant of the county of Gömör. Of his literary works the most famous is the epic poem *Murányi Venus* (Caschau, 1664), in honour of the wife of his benefactor Wesselényi, Maria Szécsi, the heroine of Murány. Among his later works the best known are *Rózsa-Koszorú*, or *Rose-Wreath* (1690), *Kemény-János* (1693), *Cupidó* (1695), or *Palinodia* (1695) and *Chariklia* (1700).

The earliest edition of his collected poetical works is by Dugonics (Pressburg and Pest, 1796); the best modern selection is that of Toldy, entitled *Gyöngyösi István válogatott poétai munkái* (Select poetical works of Stephen Gyöngyösi, 2 vols., 1864–65).

GYÖR, a well-built Hungarian town, capital of a county of the same name, situated at the confluence of the Raab with an arm of the Danube, with the main stream of which it has communication by river steamers. The town occupies the site of the Roman *Arabona* and has always been an important regional centre and in earlier days a powerful fortress which the Turks

captured by treachery in 1594 but retained for four years only. Throughout history it has been regarded as the key to passage east and west as is exemplified by the French storming in 1809 and that by the Austrians in 1849. In the 11th century the town was made a Roman Catholic bishopric and its fine cathedral dating from the 12th century in origin, though rebuilt in 1639-54, has gathered around it many important expressions of spiritual leadership, e.g., the seminary for priests.

The modern functions are based upon its position at the contact of the old alluvial plain and the drained marshes, and mixed farming has originated an active trade in cereals and horses, which is supplemented by milling, textile manufactures, linen and wool, and the distillation of spirits. Pop. (1920), 50,036. About 11 m. S.E. of Győr on a spur of the Bakony Forest, lies the famous Benedictine abbey of Pannonhalma (Ger. *St. Martinsberg*; Lat. *Mons Sancti Martini*), one of the oldest and wealthiest abbeys of Hungary. It was founded by King St. Stephen, and the original deed from 1001 is preserved in the archives of the abbey. The present building is a block of palaces, containing a beautiful church, some of its parts dating from the 12th century, and is situated on a hill 1,200 ft. high. In the convent there are a seminary for priests, a normal school, a gymnasium and a library of 120,000 volumes. The chief abbot has the rank of a bishop.

GYP, the pen name of SIBYLLE GABRIELLE MARIE ANTOINETTE RIQUET DE MIRABEAU, Comtesse de Martel de Janville (1850-), French writer, born at the château of Koetsal in the Morbihan. Her father served in the Papal Zouavos, and died during the campaign of 1860. Her mother, the comtesse de Mirabeau, contributed to the *Figaro* and the *Vie parisienne* under various pseudonyms, papers in the manner successfully developed by her daughter. Under the pseudonym of "Gyp" Madame de Martel married in 1869, sent to the *Vie parisienne*, and later to the *Revue des deux mondes*, a large number of social sketches and dialogues, afterwards reprinted in volumes. Her later work includes stories of a more formal sort differing but little from the shorter studies. The following list includes some of the best known of Madame de Martel's publications, nearly seventy in number: *Petit Bob* (1882); *Autour du mariage* (1883); *Ce que femme veut* (1883); *Le Monde à Côté* (1884); *Sans voiles* (1885); *Autour du divorce* (1886); *Dans le train* (1886); *Mademoiselle Loulow* (1888); *Bob au salon* (1888-89); *L'Education d'un prince* (1890); *Passionette* (1891); *Ohé! la grande vie* (1891); *Une Élection à Tigresur-mer* (1890), an account of "Gyp's" experiences in support of a Boulangist candidate; *Mariage Civil* (1892); *Les bons docteurs* (1892); *Du haut en bas* (1893); *Mariage de chiffon* (1894); *Leurs ames* (1895); *Le Cœur d'Ariane* (1895); *Le Bonheur de Ginette* (1896); *Totote* (1897); *Lune de miel* (1898); *Israël* (1898); *L'Entrevue* (1899); *Le Pays des champs* (1900); *Trop de chic* (1900); *Le Friquet* (1901); *La Fee* (1902); *Un Mariage chic* (1903); *Un Menage dernier cri* (1903); *Maman* (1904); *Le Cœur de Pierrette* (1905); *L'Amoureux de Lone* (1910). A number of these were adapted by the author into successful plays. From the first "Gyp" writing of a society to which she belonged, showed an intense faculty of observation, much skill in innuendo, a mordant wit combined with some breadth of humour, and a singular power of animating ordinary dialogues without destroying the appearance of reality. Her Parisian types of the spoiled child, of the precocious school-girl, of the young bride, and of various masculine figures in the gay world, have become noted, and many survive as faithful pictures of luxurious manners in the 19th century. Some of her later productions were inspired by a violent anti-Semitic and Nationalist bias. In 1901 Madame de Martel furnished a sensational incident in the Nationalist campaign during the municipal elections in Paris. Because of her political attitude she was kidnapped and made the victim of a considerable amount of horseplay.

GYPSIES, a wandering folk, scattered through every European land, over the greater part of western Asia and Siberia; found also in Egypt and the northern coast of Africa, in America and even in Australia. No correct estimate of their numbers outside of Europe can be given, and even in Europe the information

derived from official statistics is often contradictory and unreliable.

Popular Names.—The Gypsies are known principally by two names which can easily be traced to one or other of two distinct stems. The one group, embracing the majority of Gypsies in Europe, the compact masses living in the Balkan Peninsula, Rumania and Transylvania and extending also as far as Germany and Italy, are known by the name *Atzigan* or *Atsigan*, which becomes in time Tshingian (Turkey and Greece), Tsigan (Bulgarian, Servian, Rumanian), Czigany (Hungarian), Zigeuner (German), Zingari (Italian), the English word Tinker or Tinkler (the latter no doubt due to popular etymology) being perhaps a local transformation of the German *Zigeuner*. The second name, partly known in the East as an expression of contempt, is *Egyptian*; in England, Gypsy; in some German documents of the 16th century *Aegypter*; Spanish *Gitano*; modern Greek *Gyphos*. They are also known by the parallel expressions *Faraon* (Rumanian) and *Phárao Nephka* (Hungarian) or Pharaoh's people, which are only variations connected with the Egyptian origin. The habit of ascribing an Egyptian origin to people reputed to be possessed of magical powers has long persisted. The name, Egyptians, is derived from a peculiar tale which the gypsies spread when appearing in the west of Europe. They alleged that they had come from a country of their own called Little Egypt, either a confusion between Little Armenia and Egypt or the Peloponnesus.

In the Syriac version of the apocryphal Book of Adam, known as the *Cave of Treasures* and compiled probably in the 6th century occurs the passage: "And of the seed of Canaan were as I said the Aegyptians; and, lo, they were scattered all over the earth and served as slaves of slaves" (ed. Bezold, German translation, p. 25). No reference to such a scattering and serfdom of the Egyptians is mentioned anywhere else. This must have been a legend, current in Asia Minor, and hence probably transferred to the swarthy Gypsies.

In France they are known as *Bohémiens*. Other names have been bestowed upon them, such as Walachi, Saraceni, Agareni, Nubiani, etc. They were also known as Tartars in Germany, or as "Heathens," *Heydens*. As to the origin of the name *Atzigan*, Miklosich derives the word from the Athinganoi, a name originally belonging to a peculiar heretical sect living in Asia Minor near Phrygia and Lycaonia, known also as the Melki-Zedekites. The members of this sect observed very strict rules of purity, as they were afraid to be defiled by the touch of other people whom they considered unclean. They therefore acquired the name of Athinganoi (i.e., "Touch-me-nots"), who are described by Byzantine historians of the 9th century as sooth-sayers, magicians and serpent-charmers.

The Gypsies of Europe who, starting from the ancient Byzantine empire have travelled westwards and spread over Europe, America and Australia call themselves by the name of Rom, the woman being Romni and the stranger Gazi. Many etymologies have been suggested for the word Rom. Miklosich identified it with Doma or Domba, a low caste of Upper India. This agrees with the view that "the language of European Gypsies" shows many points of correspondence with the dialect of Indian Gypsy tribes such as the Doms. . . . The language of the Gypsies of Europe, however, points towards the extreme north-west of India and . . . the hypothesis might be hazarded that members of the same vagrant race from which the Indian Gypsies are descended come up to the north-west and remained there long enough to adapt their language to the practice prevailing among frontier tribes. Some of them passed on before this adaptation took place and became the ancestors of the Armenian Gypsies whose language does not point to the north-west frontier but rather to Hindustan. The bulk of these Gypsies later on brought their language, as modified among frontier tribes, to Europe, and became the ancestors of the Romany Chals (*Linguistic Survey of India*, vol. xi, 1922, p. 11). Another view, supported by a careful examination of phonetic data, is that the language is of the central group with evidence of a later migration to and contact with the north-west group of Sanskrit languages in India. Gaster suggested that having no home and no country of their own and no political

traditions and no literature, they would naturally identify themselves with the people in whose midst they lived, and called themselves Rom (cf. *Romaioi*, *Romanoi*), a natural name, and flattering to their vanity. This origin of the name would explain why it is limited to the European Gypsies.

HISTORY

Appearance in Europe.—The first appearance of Gypsies in Europe cannot be traced further back than the beginning of the 14th century.

At least three centuries before historical evidence proves the immigration of the genuine Gypsy, there had been wayfaring smiths, travelling from country to country. Their successors, the Gypsies, took up their crafts and probably assimilated a good proportion of these vagrants of the west of Europe. The name given to the former, who probably were Oriental or Greek smiths and pedlars, was then transferred to the new-comers. Hopf has proved the existence of Gypsies in Corfu before 1326. Before 1346 the empress Catherine de Valois granted to the governor of Corfu authority to reduce to vassalage certain vagrants who came from the mainland.

By the end of the 15th century they must have been settled for a sufficiently long time in the Balkan Peninsula and the countries north of the Danube, such as Transylvania and Walachia, to have been reduced to the same state of serfdom as prevailed in Corfu in the second half of the 14th century. At that time there must already have been in Walachia settled Gypsies treated as serfs, and migrating Gypsies plying their trade as smiths, musicians, dancers, sooth-sayers, horse-dealers, etc., for we find the voivode Alexander of Moldavia granting these Gypsies in the year 1478 "freedom of air and soil to wander about and free fire and iron for their smithy." But a certain portion, probably the largest, became serfs, to be sold, exchanged and inherited. The Gypsies followed at least four distinct pursuits in Rumania and Transylvania, where they lived in large masses. A goodly proportion of them were tied to the soil; in consequence their position was different from that of the Gypsies who had started westwards and who are nowhere found to have obtained a permanent abode for any length of time, or to have been treated, except for a very short period, with any consideration of humanity.

Their appearance in the West is first noted by chroniclers early in the 15th century. In 1414 they are said to have already arrived in Hesse. In 1418 they reached Hamburg, 1419 Augsburg, 1428 Switzerland. In 1427 they had entered France (Provence). A troupe is said to have reached Bologna in 1422, on a pilgrimage to Rome, undertaken for some act of apostasy. After this first immigration a second and larger one seems to have followed in its wake, led by Zumbel. The Gypsies spread over Germany, Italy and France between the years 1438 and 1512. About 1500 they must have reached England.

The Act of Henry VIII. 22, c. 10 dealt with the Gypsy problem in England. Albert Krantz (Krantz), in his *Saxonia* (xi. 2), says that in the year 1417 there appeared for the first time in Germany a people uncouth, black, dirty, barbarous, called in Italian "Ciani," who indulge specially in thieving and cheating. They had among them a count and a few knights well dressed, others followed afoot. The women and children travelled in carts. They also carried with them letters of safe-conduct from the emperor Sigismund and other princes, and they professed that they were engaged on a pilgrimage of expiation for some act of apostasy. This people have no country and travel through the land. They live like dogs and have no religion although they allow themselves to be baptized in the Christian faith. They live without care and gather unto themselves also other vagrants, men and women. Their old women practise fortune-telling, and whilst they are telling men of their future they pick their pockets. He uses the name by which these people were called in Italy, "Ciani." Crusius, the author of the *Annales Suevici*, knows their Italian name *Zigani* and the French *Bohémiens*. Not one of these oldest writers mentions them as coppersmiths or farriers or musicians.

Later History.—Edicts were issued in many countries from the

end of the 15th century onwards sentencing the "Egyptians" to exile under pain of death. In Edinburgh four "Faas" were hanged in 1611 "for abiding within the kingdome, they being Egiptienis," and in 1636 at Haddington the Egyptians were ordered "the men to be hangied and the weomen to be drowned, and suche of the weomen as hes children to be scourgit throw the burg and burnt in the cheeks." The burning on the cheek or on the back was a common penalty. In 1692 four Estremadura Gypsies caught by the Inquisition were charged with cannibalism and made to own that they had eaten a friar, a pilgrim and even a woman of their own tribe, for which they suffered the penalty of death. In 1782, 45 Hungarian Gypsies were charged with a similar crime, and when the supposed victims of a supposed murder could not be found on the spot indicated by the Gypsies, they owned under torture and said on the rack, "We ate them." Of course they were forthwith beheaded or hanged. The emperor Joseph II., author of one of the first edicts in favour of the Gypsies, ordered an inquiry into the incident; it was then discovered that no murder had been committed, except that of the victims of this monstrous accusation.

In 1907 a "drive" was undertaken in Germany against the Gypsies. In 1904 the Prussian Landtag adopted unanimously a proposition to examine anew the question of granting peddling licences to German Gypsies; that on the 17th of February 1906 the Prussian minister issued special instructions to combat the Gypsy nuisance; and in various parts of Germany and Austria a special register was kept for the tracing of the genealogy of vagrant and sedentary Gypsy families.

In Rumania they were divided mainly into two classes, (1) *Robi* or Serfs, who were settled on the land and deprived of all individual liberty, being the property of the nobles and of churches or monastic establishments, and (2) the Nomadic vagrants. They were subdivided into four classes according to their occupation, such as the *Lingurari* (woodcarvers; lit. "spoon-makers"), *Caldarari* (tinkers, coppersmiths and ironworkers), *Ursari* (lit. "bear drivers") and *Rudari* (miners), also called *Aurari* (gold-washers), who used formerly to wash the gold out of the auriferous river-sands of Walachia. A separate and smaller class consisted of the Gypsy *Lăeshi* or *Vătrashi* (settled on a homestead or "having a fireplace" of their own). Each *shatra* or Gypsy community was placed under the authority of a judge or leader, these officials were subordinate to the *bulubasha* or *voivod*, who was himself under the direct control of the *yuzbasha* (or governor appointed by the prince from among his nobles). The *yuzbasha* was responsible for the regular income to be derived from the vagrant Gypsies, who were considered and treated as the prince's property. These voivodi or yuzbashi who were not Gypsies by origin often treated the Gypsies with great tyranny. The *Robi* could be bought and sold, freely exchanged and inherited, and were treated as the negroes in America down to 1856, when their final freedom in Moldavia was proclaimed. In Hungary and in Transylvania the abolition of servitude in 1781-1782 carried with it the freedom of the Gypsies. In 1866 the Gypsies became Rumanian citizens. On Jan. 6, 1906 the first Gypsy Congress was held in Sofia, for the purpose of claiming political rights for the Turkish Gypsies or Gopti as they call themselves.

RELIGION, HABITS AND CUSTOMS

Their religious views are a strange medley of the local faith, which they everywhere embrace, and some old-world superstitions which they have in common with many nations. Among the Greeks they belong to the Greek Church, among the Mohammedans they are Mohammedans, in Rumania they belong to the National Church. In Hungary they are mostly Catholics, according to the faith of the inhabitants of that country. They have no ethical principles and they do not recognize the obligations of the Ten Commandments. There is extreme moral laxity in the relation of the two sexes, and on the whole they take life easily and are complete fatalists. At the same time they are great cowards and they play the rôle of the fool or the jester in the popular anecdotes of eastern Europe. There the poltroon is always a Gypsy, but he is good-humoured and not so malicious as

those Gypsies who had endured outlawry in the west of Europe.

There is nothing specifically of an Oriental origin in their religious vocabulary. In general their beliefs, customs, tales, etc., belong to the common stock of general folklore, and many of their symbolical expressions find their exact counterpart in Rumanian and modern Greek, and often read as if they were direct translations from these languages. The nomadic Gypsies carry on the ancient craft of coppersmiths, or workers in metal; they also make sieves and traps, but in the East they are seldom farriers or horse-dealers. They are far-famed for their music, in which art they are unsurpassed. The Gypsy musicians were the troubadours and minstrels of eastern Europe. Liszt ascribed to the Gypsies the origin of the Hungarian national music. This is an exaggeration. Equally famous is the Gypsy woman for her knowledge of occult practices. She is the real witch; she knows charms to injure the enemy or to help a friend. She can break the charm if made by others. They use either the local language of the natives in the case of charms, or a slightly Romanized form of Greek, Rumanian or Slavonic. The old Gypsy woman is also known for her skill in palmistry and fortune-telling by means of a special set of cards, the well-known Tarok of the Gypsies. They have also a large stock of fairy tales resembling in each country the local fairy tales, in Greece agreeing with the Greek, and in Rumania with the Rumanian fairy tales.

Physical Characteristics.—They are of small stature, varying in colour from the dark tan of the Arab to the whitish hue of the Serbian and the Pole. There are some white-coloured Gypsies, especially in Serbia and Dalmatia, who are often not easily distinguishable from the native peoples, except that they are more lithe and sinewy, better proportioned and more agile in their movements than the thick-set Slavs and the mixed race of the Rumanians, distinguishable by the lustre of their eyes and the whiteness of their teeth. Some are well built; others have the features of a mongrel race, due no doubt to intermarriage with outcasts of other races. The women age very quickly. They love display and Oriental showiness, bright-coloured dresses, ornaments, bangles, etc.; red and green are the colours mostly favoured by the Gypsies in the East. Along with a showy handkerchief or some shining gold coins round their necks, they will wear torn petticoats and no covering on their feet.

Social Structure.—There is evidence that among English Gypsies certain groups were matrilineal and others patrilineal. Their marriage system did not preclude marriage with nieces (brother's daughter) with grand-daughters or half sisters though common parentage was long a bar. Marriages of aunt and nephew are rare. Cousin marriages were frequent. The ortho-cousin marriage occurred frequently. Matrilocal marriages are definitely recorded. In the cross cousin marriage the daughter of the maternal uncle was preferred. Polygamy was practised. The levirate is uncommon. The Sororate is known. The common rule required the elder sister to marry before the younger. Proofs of fitness were demanded of the man and of chastity from the girl. Marriage was by elopement, ratified by a public ceremony—with the approval of the headman. The ceremony consisted of joining hands, or of eating a cake containing the blood of both parties, or of jumping over a branch or besom or tongs. The wife had to be lifted and carried to the tent for the consummation of the union. These rites can be illustrated from India and elsewhere, and are in part fertility rites, in part, protective. For an account of the Gypsy language see ROMANY LANGUAGE.

BIBLIOGRAPHY.—The Gypsy Lore Society has published an elaborate bibliography which should be consulted for works on the origin, history, customs, institutions, language, etc., of the Gypsies. (M. G.)

American.—In spite of the fact that most of the descendants of the Gypsies who came in colonial times from Great Britain, Holland, Germany and France have been absorbed, there were probably in America in 1928 between 50,000 and 100,000 of Romani blood; and the number is increasing. The majority arrived during the last quarter of the 19th century. British Gypsies are fairly numerous in the United States and Canada, and differ little from those of the Old World. Since the decline of horse trading, their chief occupation has been that of fortune-telling;

some have settled on farms, and others peddle oil-cloth, hand-made baskets and rustic furniture. Some Hungarian Gypsy musicians dwell in houses. More than half use Romani as their native tongue. The largest group is at Braddock, Pennsylvania. However, Russian or Rumanian Gypsy singers and violinists are rare. Families of Turkish, Syrian, Bulgarian and Spanish gypsies are extremely scattered.

The majority of Gypsies in America might be vaguely classified as Vlach. There are two distinct varieties. The smaller is known as the *Karavase* (black Vlachs), or *Baiaš* (gold-washers). What little Romani they speak has been picked up from Anglo-American gypsies. Rumanian is their "secret" tongue, though they lived in Serbia for a time before starting on their wide migrations. Of these a number are bear-leaders, and nearly all are fortune-tellers. The other variety forms the bulk of American Gypsies. For lack of a better term we must call them the nomads. Among themselves they speak a relatively pure dialect of Romani; but the percentage of Rumanian loan-words would indicate that at one time they nomadized in Vlach countries. They may be met anywhere, from China to Africa; but nowhere as frequently as in the United States. There are also large numbers in South America. They subdivide themselves into tribes: the *Mačvaya*, so named from a region in northern Serbia, the *Kalderds*, from their former profession as coppersmiths, *Rúsores*, *Ungésores*, etc., from the countries where they lived longest before coming to America. In spite of slight differences of dialect and customs, these tribes are homogeneous, and mix with no other group, not even the *Baiaš*. They have their own courts (*romano-kris*), conducted in the manner of the Gypsy-like peoples of India. Taboos are strictly enforced and punished by fines, or expulsion from the tribe, *mah-rimé* (defilement, rejection).

The large silk kerchief, worn over the head by the married women, the necklaces of gold coins, the gay dresses, are distinctive. They travel by train and motor car and live by the fortune-telling of the women. Formerly most of them were coppersmiths. A few are professional musicians, and nearly all have a talent for music. They have preserved many stories and songs in their own language. In summer they live in tents; but during the cold months they move into the cities, where they live in stores. Prosperity is tending to Americanize them; but like all Romanies they readily revert to age-old traits.

GYPSUM, a common mineral consisting of hydrous calcium sulphate, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ named from the Gr. *γύψος*, a word used by Theophrastus to denote not only the raw mineral but also the product of its calcination, which was employed in ancient times, as it still is, as a plaster. When crystallized, gypsum is often called selenite, the *σεληνίτης* of Dioscorides, so named from *σελήνη*, "the moon," probably in allusion to the soft moon-like reflection of light from some of its faces, or, according to a legend, because it is found at night when the moon is on the increase. The granular, marble-like gypsum is termed alabaster (*q.v.*).

Gypsum crystallizes in the monoclinic system, the habit of the crystals being usually either prismatic or tabular; in the latter case the broad planes are parallel to the faces of the clinopinacoid. The crystals may become lenticular by curvature of certain faces. Twins are common, forming in some cases arrow-headed and swallow-tailed crystals. Cleavage is perfect parallel to the clinopinacoid, yielding thin plates, often diamond-shaped, with pearly lustre; these flakes are usually flexible, but may be brittle, as in the gypsum of Montmartre. Two other cleavages are recognized, but they are imperfect. Crystals of gypsum, when occurring in

clay, may enclose much muddy matter; in other cases a large proportion of sand may be mechanically entangled in the crystals without serious disturbance of form; whilst certain crystals occasionally enclose cavities with liquid and an air-bubble. A fibrous variety occurs in veins, often running through marls, with the fibres disposed at right angles to the direction of the vein. Such gypsum when cut and polished has a pearly opalescence, or satiny sheen, whence it is called satin-spar (*q.v.*).

Gypsum is so soft as to be scratched even by the finger-nail ($H=1.5$ to 2). Its specific gravity is about 2.3 . The mineral is slightly soluble in water, one part of gypsum being soluble, according to G. K. Cameron, in 372 parts of pure water at 26° C. Waters percolating through gypseous strata, like the Keuper marls, dissolve the calcium sulphate and thus become permanently hard or "selenitic." Such water has special value for brewing pale ale, and the water used by the Burton breweries is of this character; hence the artificial dissolving of gypsum in water for brewing purposes is known as "burtonization." Deposits of gypsum are formed in boilers using selenitic water.

Pure gypsum is colourless or white, but it is often tinted, especially in the alabaster variety, grey, yellow or pink. By exposure to strong heat all the water may be expelled, and the substance then has the composition of anhydrite (*q.v.*). When the calcination, however, is conducted at such a temperature that only about 75% of the water is lost, it yields a white pulverulent substance, known as "plaster of Paris," which may readily be caused to recombine with water, forming a hard cement. The gypsum quarries of Montmartre, in the north of Paris, were worked in Tertiary strata, rich in fossils. Gypsum is largely quarried in England for conversion into plaster of Paris, whence it is sometimes known as "plaster stone," and since much is sent to the Staffordshire potteries for making moulds it is also termed "potter's stone." The chief workings are in the Keuper marls near Newark in Nottinghamshire, Fauld in Staffordshire and Chellaston in Derbyshire. It is also worked in Permian beds in Cumberland and Westmorland, and in Purbeck strata near Bournemouth in Sussex. The principal American workings are in New York, California, Iowa, Kansas, Texas, Ohio, Oklahoma, Michigan, Wyoming, Nova Scotia and New Brunswick.

Gypsum frequently occurs in association with rock-salt, having been deposited in shallow basins of salt water. Much of the calcium in sea-water exists as sulphate; and on evaporation of a drop of sea-water under the microscope this sulphate is deposited as acicular crystals of gypsum. In volcanic districts gypsum is produced by the action of sulphuric acid, resulting from the oxidation of sulphurous vapours, on lime-bearing minerals, like labradorite and augite, in the volcanic rocks: hence gypsum is common around solfataras. Again, by the oxidation of iron-pyrites and the action of the resulting sulphuric acid on limestone or on shells, gypsum may be formed; whence its origin in most clays. Gypsum is also formed in some cases by the hydration of anhydrite, the change being accompanied by an increase of volume to the extent of about 60%. Conversely gypsum may, under certain conditions, be dehydrated or reduced to anhydrite.

Some of the largest known crystals of selenite have been found in southern Utah, where they occur in huge geodes, or crystalline cavities, in deposits from the old salt-lakes. Fine crystals, sometimes curiously bent, occur in the Permian rocks of Friedrichroda, near Gotha, where there is a grotto called the Marien-glashöhle, close to Rheinhardtbrunn. Many of the best localities for selenite are in the New Red Sandstone formation (Trias and Permian), notably the salt-mines of Hall and Hallein, near Salzburg, and of Bex in Switzerland. Excellent crystals, usually of a brownish colour arranged in groups, are often found in the brine-chambers and the launders used in salt-works. Selenite also occurs in fine crystals in the sulphur-bearing marls of Girgenti and other Sicilian localities; whilst in Britain very bold crystals are yielded by the Kimeridge clay of Shotover Hill near Oxford. Twisted crystals and rosettes of gypsum found in the Mammoth Cave, Kentucky, have been called "oulopholites" (*οὐλος*, "woolly"; *φωλεός*, "cave").

In addition to the use of gypsum in the making of Keene's cement, plaster of Paris, fireproof building blocks, wall and parti-

tion material, foundry cores, the mineral finds application as an agricultural agent in dressing land, and it has also been used in the manufacture of porcelain and glass. Formerly it was employed, in the form of thin cleavage-plates, for glazing windows, and seems to have been, with mica, called *lapis specularis*. It is still known in Germany as *Marienglas* and *Frauenfels*. Delicate cleavage-plates of gypsum are used in microscopic petrography for the determination of certain optical constants in the rock-forming minerals.

(R. H. RA.)

GYPSY MOTH, a European Liparid moth (*Porthetria dispar*) brought to the United States for experiment in 1869 but escaped from confinement, multiplied slowly, and eventually became a great woodland and orchard pest in New England. In 1888 and 1889 it had become very abundant in the vicinity of Medford, Mass., and its identity with the European species was ascertained. It was found to have spread over an area of nearly 400 sq.m. in the vicinity of Boston. For ten years effective work was carried on by the State of Massachusetts, and the insect was kept under measurable control. The State discontinued its work in 1900, and by 1905 it had spread over an area of approximately 4,000 sq.m. In 1906 it was found in the States of New Hampshire and Rhode Island, and an appropriation was made by Congress in an attempt at its control by the Federal Government. Annual appropriations for this purpose have been continued by the Government since that time. The spread of the species has been retarded greatly, and the damage done by it has been much reduced. By State and Federal quarantine measures, commercial spread has been prevented to a large extent. Five centres of infestation have been found beyond New England, namely at Geneva, N.Y., Cleveland, O., in Westchester County, N.Y., at Rutherford, N.J., and at Somerville, N.J. All of these outbreaks have been exterminated except the last, and it is expected that the extermination of this outbreak will be accomplished soon. In the meantime, however, the insect has spread over all of Rhode Island, throughout the southwestern part of Maine, and by far the larger part of Connecticut, Massachusetts and New Hampshire, as well as rather more than half of Vermont. At present a strenuous effort is being made by the Federal Government and by the State of New York to hold it within its present limits.

The adult female moth is a heavy-bodied, light coloured insect, with zigzag blackish marks on the wings. The body is so heavy that the female cannot fly. It has a wing-spread of $2\frac{1}{2}$ in. The male is much smaller, is dark in colour, and flies readily. The winter is passed in the egg stage. The eggs are laid in clusters of four hundred or more, on the bark of trees, on fence rails, fallen logs, under loose bark, in cavities in the trunks or branches and are sometimes placed on stones where they may be concealed from view. Each cluster is covered with buff-coloured hair. The eggs are laid during July, and hatch with the appearance of the leaves the following spring. The young larvae feed rapidly and become full-grown early in July. They are ravenously eaters, and when they are numerous the trees may be stripped completely before the end of June. The pupae, or chrysalids, into which the larvae are changed give out the adult moths after about ten days. There is one generation each year. The gypsy moth spreads commercially on nursery stock, young trees, lumber, stone or other products likely to be sent away. They also spread as newly hatched caterpillars, in which condition they are blown to considerable distances by the wind on warm sunny days. The insect is a very destructive enemy to mixed forests and to orchards. In New England thousands of trees have been killed. Apple and oak have suffered more than other species, but pine and other coniferous trees have been killed when mixed with deciduous growth. The remedial measures adopted after long investigation have consisted of spraying with a solution of arsenate of lead, banding the trees to prevent the climbing of the caterpillars, and treatment of the egg-masses with creosote. Many species of parasites have been introduced from Europe, and certain of these, especially the Braconids and the Tachina flies, have proved reasonably effective. A predatory beetle known as *Calosoma sycophanta* has also been introduced to good effect. These imported natural enemies have been the means of aiding very considerably in the control of the insect. GYRO-COMPASS or **GYROSCOPIC COMPASS** is an instrument invented and developed in comparatively recent years. It was the outcome of an increasing need for a reliable compass which would not be subject to the troubles caused by the larger and larger masses of steel in ships. As gyroscopes and gyroscopic reactions became better understood, experiments along these lines resulted, finally, in the successful application of the gyroscope to obtain a compass which would indicate geographic north, and at the same time be immune from the magnetic disturbances inevitable on all steel ships. In 1911 the compass which now has had the widest adoption in shipping successfully completed its trials, first on a merchant ship operating between New York and Norfolk, Va., and then in the powder magazine of a torpedo boat destroyer. It was installed on a U.S. battleship and two "repeater" compasses were electrically connected to it, one used for steering and the other for taking bearings. It was soon found that the gyro-compass, on account of its integrity and its refusal to take up any of the yawing movements of the ship, afforded a base line from which graphic course records could be made and turret guns controlled in azimuth. Eventually the master gyro-compass became a most important factor of the gun control system. After the first successful trials, gyro-compasses were rapidly installed on battleships and submarines throughout the U.S. navy, and were further taken up by the British, Japanese, French, Italian and Russian navies in the order named; in the years following the war, the gyro-compass was also adopted by a majority of the important merchant fleets throughout the world.

In addition to the compass mentioned above, which is manufactured by the Sperry Gyroscope company in the borough of Brooklyn, New York city, a gyro-compass is also manufactured by the Anschütz company in Germany. Still later there has appeared a compass manufactured by S. G. Brown in Great Britain, and still more recently one made by the Arma company in New York. With each, the operation is based upon the same fundamental principles, the method in which the gyroscopic element (from which the compass obtains its directive force) is suspended being the chief difference. The Anschütz compass employs the flotation method, the Brown the so-called "oil pump" method, and the Arma the flotation method; while with the Sperry compass the weight of the sensitive element is supported by a mechanical method.

The Component Parts.—The compass first mentioned above consists, essentially, of a gyro wheel driven at moderately high speed by electricity, its auxiliary parts and compass card all supported in gimbals in a suitable housing or binnacle. The compass is in reality built up around the gyro wheel. When the compass is functioning normally, its spinning axis will lie in line with the true north-south meridian. The gyro wheel and shaft are supported in a housing called the rotor-case, which is fitted with the necessary oil reservoirs to supply lubrication to its main bearings for many months. The weight of the rotor-case is supported in turn in two ball bearings, one on either side, from a surrounding ring called the vertical ring, which lies in a vertical plane at right-angles to the gyro axis. The vertical ring is supported by means of a stranded wire suspension from the head of the compass at the centre of the compass card, and is suitably guided. In order to prevent lag due to friction, however, between the compass card and the gyroscopic element which is suspended from it, the vertical ring is suspended within an outer or "phantom" ring which is rigidly attached at the upper end to the compass card itself. The phantom element, including the compass card, is kept in line with the sensitive element by a reversible motor (called the azimuth motor) which is controlled through a trolley and contactor circuit and applies a small oscillation or "hunt" to the compass card. The weight of the card and phantom ring is supported on thrust bearings by the main frame. Surrounding the phantom ring is a frame called the ballistic, which is supported on ball-bearings carried on either side of the phantom ring. This ballistic frame contains reservoirs which are connected by tubes, so that the

liquid is free to flow from one side to the other in a direction parallel to the gyro axis. The ballistic frame is connected to the rotor-case by means of an arm called the link, which fits over a bearing on the bottom of the case. It is through this connection that the force of gravity generated by the ballistic is applied to the sensitive element, causing the gyro axis to seek and maintain the meridian. Although the gyro-compass is absolutely free from magnetic variation and deviation, correction must be made for latitude and speed. The reason for this is that the progress of a ship over the earth's surface creates an effect on the gyro-compass similar to that resulting from the earth's rotation itself. If this movement of the ship is east or west, the effect upon the compass is nil, but if the ship moves north or south or in a direction which is a component of a north or south heading, the axis of the gyro is triflingly displaced from the axis of the earth by an amount depending upon the latitude, the speed of the ship and the direction of the heading. The error resulting from this displacement is automatically eliminated in the Sperry compass by means of a corrector so contrived as to utilize the very disturbing elements themselves to introduce the proper correction; so that all readings of the compass together with all repeaters and other instruments driven therefrom are true to the meridian.

The main frame of the master compass is provided with a lubber-ring concentric with the compass card and rigid except for the small movement applied to it by the corrector mechanism described above. A lubber-line or base-line inscribed on this ring provides the necessary references, so that when the compass has been installed with the lubber-line parallel to the fore and aft line of the ship, the angle between the ship's head and the true geographic meridian may be read in degrees and fractions from the compass card. A transmitter forming a part of the compass transmits correct azimuth to all repeaters and other auxiliaries. The master compass as described above, together with its subordinate parts, is supported in gimbal rings in a hollow, cylindrical body or binnacle. One form of the binnacle is provided with two sliding doors which can be unlatched from the top and lowered to provide access to the compass. The binnacle has a hinged cover with a large glass window so that the operation of the compass may be viewed with the dust-proof cover closed.

A gyro-compass equipment usually includes a motor generator for converting the ship's supply current to alternating current of the proper characteristics to drive the gyro wheel, a control panel with suitable switches and meters for operating the equipment, and a number of repeater compasses for indicating the compass readings wherever required. To these more or less fundamental units other equipment is frequently added, such as a *course recorder* for automatically recording the ship's course, and the *gyro-pilot* which steers the ship automatically from the gyro-compass.

Method of Application.—On merchant vessels the master gyro-compass is usually placed below decks in a clean and dry compartment. A steering repeater fitted with a reading glass is located beside the ship's wheel and adjusted to suit the convenience of the helmsman. Bearing repeaters are mounted on the port and starboard wings of the bridge, and a repeater is often placed aft at the emergency steering station. Repeaters with bulk-head mounting may be used in the captain's stateroom and in the wireless room, and if the ship is equipped with a wireless direction-finder, a repeater compass is almost always used in conjunction with it to obtain accurate wireless bearings. The course recorder is located in the chartroom, where its record is available for inspection at all times by the captain and officers of the ship. While a magnetic compass is still standard equipment on every vessel, it is fast coming to be considered simply as a standby in case anything should go wrong with the gyro. The gyro-compass is an instrument capable of withstanding considerable rough treatment. It is not affected by the vibration of the ship's engines on account of the resilient support of the gyro. The gyro is likewise carefully balanced in such a way that it is not affected by the rolling and pitching of the ship.

Operating Principles.—The principles upon which the operation of the gyro-compass is based depend upon the fundamental

THE "AUTOGIRO" OR GYROPLANE

1. The de la Cierva Autogiro fitted with a 200 h.p. engine, with wings at rest. This type of aeroplane was originated in Spain between 1919 and 1924 by Juan de la Cierva. The wings rotate about an approximately vertical axis. No driving power is supplied to them mechanically, their rotation being dependent on the forward motion of the whole machine
2. Arrangement of axle of rotating wings on the "Autogiro." An essential feature is the hinging of each of the wings round an axis perpendicular to the spindle about which they all rotate
3. Señor de la Cierva, inventor of the Autogiro, landing at Le Bourget field, Paris, after a successful flight across the English Channel
4. The Autogiro in flight. The machine can be banked in the same way as an ordinary aeroplane. The "Autogiro" is capable of a minimum flying speed as low as 30 miles per hour. It can glide safely at so steep an angle that it appears to the eye to be descending vertically, and on touching the ground it stops within a few yards

characteristics of gyroscopic action, and may readily be observed with the aid of a small gyroscope model. A typical gyroscope may briefly be described as a spinning wheel, universally mounted; *i.e.*, the wheel shaft is so mounted in supporting rings that its axis is free to take up any position in space. On spinning the wheel in either direction it will be found to have assumed a *rigidity of direction of its axis and plane of rotation relative to space*. It can be carried about on its support in any manner without changing the direction of its axis relative to space. With the wheel still spinning, the gyro will exhibit another interesting trait. Apply a pressure against its supporting ring in a direction calculated to move the wheel about the horizontal axis; instead of moving in the direction of the applied force, the supporting ring will resist the pressure and move about the vertical axis—at right angles to the applied force. Similarly, if a pressure be applied about the vertical axis of the gyroscope, it will resist the pressure in this direction and move about the horizontal axis. This phenomenon is known as *precession*.

FIG. 1.—GYROSCOPE WITH A TUBE OF LIQUID STRAPPED TO THE FRAME FOR APPLIANCE OF FORCE OF GRAVITY

The gyro-compass exhibits the same characteristics as the simple model described above, within practical limits, only in the case of the gyro-compass the precessional movement is controlled by the force of gravity in the form of the ballistic previously alluded to. Otherwise it would merely be a gyroscope, without any north-seeking quality whatsoever. Returning now to the elementary gyroscope model, imagine it placed on the earth's surface at the equator with its spinning axis in an east-west direction. Because of the model's *rigidity-in-space* characteristic it will maintain its axis in the same plane with regard to space, though to an observer standing beside it on the earth's surface the end toward the east appears to tilt up as the earth revolves from west to east, moving the base of the gyroscope just as if it were moved by hand as described above. If left alone, the gyro axis would apparently make a complete revolution every 24 hours and, disregarding the effect of friction in the bearings, it would always have its axis in the original east-west plane.

Recalling the effect of precession on the revolving wheel, the natural force of gravity may now be applied by strapping a semicircular tube of liquid to the frame in which the wheel of the

FIG. 2.—THE CYCLE OF MOVEMENTS OF THE GYROSCOPE STARTING FROM AN EAST-WEST POSITION, a, TO SETTLEMENT ON THE TRUE MERIDIAN, e, THUS FORMING A GYRO-COMPASS

model is suspended (fig. 1). With the model placed in the same position as described above, with its axis in the east-west direction, as the earth revolves and the axis tilts in regard to the earth the liquid flows to the low side, which we will designate as S, thus applying a force about the horizontal axis of the gyro (fig. 2). Owing to the law of precession, however, this pressure causes the gyro to turn about the vertical axis, which it proceeds to do, until the opposite end of the axis, N, reaches and crosses the north-south meridian of the earth. As soon as it has crossed the meridian, the other end of the axis S commences to tilt up,

the liquid flows to the low side N and reverses the precessional force, causing the gyro to precess back across the meridian. Thus the gyro axis will continue to oscillate across the meridian indefinitely, with the end of the axis designated as the north end N pointing toward the North Pole as it crosses the meridian.

In the case of the gyro-compass these oscillations are damped out and the gyro axis is caused to settle permanently on the meridian. The precessional force then, due to gravity, instead of acting only about the horizontal axis of the gyroscope also acts, in a much lesser extent, about the vertical axis. This small force about the vertical axis introduces (by the law of precession) a tilting movement about the horizontal which is counter to the natural tilt of the gyro axis as it approaches the meridian, and which in turn slows down or damps the precession of the gyro axis as it approaches the meridian. Thus its oscillations are damped on both sides of the meridian, and its axis will come to rest in a state of equilibrium on the meridian without outside aid, no matter where it happens to point when it is started up. (See NAVIGATION.) (E. A. SP.)

GYROPLANE, an aeroplane in which the wings are free to rotate about an approximately vertical axis. No driving power is supplied to them mechanically, their rotation being dependent

DIAGRAM OF DE LA CIERVA "AUTOGIRO," SHOWING WING MOTION. THIS IS THE ONLY EXAMPLE OF A PRACTICAL GYROPLANE

on the forward motion of the whole machine. The type was originated in Spain between 1919 and 1924 by Sr de la Cierva. In his machine (the "Autogiro") an essential feature is the hinging of each of the wings about an axis perpendicular to the spindle about which they all rotate. They are prevented from collapsing upward by centrifugal force, but they have a flapping motion, of a frequency equal to that of the rotation (100 to 130 per min.), resulting in equalisation of the lift of the advancing and retreating wings, thus balancing the machine laterally. The speed of the wing tips, due to their rotation, is about twice the forward speed of the machine.

Although the "Autogiro" cannot hover, it is capable of a very low minimum flying speed, some 30m. per hour (equivalent to that of a conventional aeroplane with a wing area equal to the circle described by the wing tips) and there appears to be no "stall" as usually understood. It can glide safely at so steep an angle that it appears to the eye to be descending vertically. On touching the ground it stops after a few yards, and can thus land safely in a very small space. The essential risk of flight in normal aeroplanes is absent, and it is this feature which may be expected to justify its inventor's confidence in its future.

In speed and useful load the "Autogiro" appears to be somewhat inferior to a normal aeroplane. In taking off it is still dependent on initial rotation of the wings by external means, and a rather long run along the ground is needed before they attain sufficient speed for flight. There is however every reason to believe that at least some of these disadvantages of this type of aeroplane will be overcome, and that it will have a marked influence on the future of flying. (See also AEROPLANE; HELICOPTER; and *Journal Royal Aeronautical Society*, Jan. 1926 and June 1927.)

GYROSCOPE, a rotating wheel universally mounted, *i.e.*, mounted in such a way that it is free to rotate about any axis. This definition is within the scientific meaning of the term, though differences of opinion exist as to the precise meaning of the word "gyroscope." Some writers use the term "gyrostat" to describe a rotatable wheel suspended with its freedom partly or wholly suppressed about one axis other than the axis of rotation. In almost every case where a gyroscope is applied to a practical purpose, its freedom is either restrained, or controlled in some manner in order to gain the desired result. One of the first instruments was that of Bohnenberger, which was constructed as early as 1810, and is described in Gilbert's *Annalen* for 1818 (vol. lx., p. 60). It consisted of a heavy spheroid which could rotate, inside a circular ring, about its shorter axis,—the axis running on pivots situated at opposite ends of the ring's diameter. This ring with its contained spheroid was similarly made movable, inside a second ring, about an axis at right-angles to the axis of the spheroid. In the same way this second ring with its contents could rotate, inside a third ring, about an axis at right-angles to each of the others. From this it will be seen that the spheroid had all degrees of free rotation, one point only within it being fixed, *viz.*, the intersection of the three axes.

In 1836, in a paper read before the Royal Scottish Society of Arts, Edward Lang suggested an experiment with an instrument exactly similar to the gyroscope, by which the rotation of the earth on its axis could be directly proved. He says: "While using Troughton's top an idea occurred to me that a similar principle might be applied to the exhibition of the rotation of the earth. Conceive a large flat wheel, poised on several axes all passing directly through its centre of gravity, and whose axis of motion is coincident with its principal axis of permanent rotation, to be put in very rapid motion. The direction of its axis would then remain unchanged. But the directions of all surrounding objects varying, on account of the motion of the earth, it would result that the axis of the revolving wheel would appear to move slowly." This suggested experiment was actually carried out, in 1852, by Léon Foucault, probably without any knowledge of Lang's suggestion. The name gyroscope was given to the instrument by Foucault at this time, and the experiment, repeated at the Liverpool meeting of the British Association, caused such a sensation that the gyroscope was brought to the notice of the public. In order to perform these early experiments successfully it was necessary to construct the instrument with the utmost exactness. Further difficulty hindered the development of the gyroscope, in that rotation could not be kept up for any length of time without functional interference causing the rotor to be inaccurate. Consequently, until comparatively recently, the gyroscope remained largely an instrument used only for demonstration purposes. It was not until the latter part of the 19th century, when G. M. Hopkins introduced the first electrically driven rotor, that the utility of the gyroscope could be fully realized.

Fundamental Principles of the Gyroscope.

—Gyroscopic phenomena are exhibited in all rotating bodies, but are more evident in those possessing large angular momentum. The angular momentum of a rotating body is dependent directly on the weight of the body, on the square of the distance at which the mass is situated from the axis of rotation and on the speed of rotation. It is therefore obvious that, for gyroscopic action to be pronounced, the spinning wheel should be heavy, the material should be disposed as far as practicable from the axis of rotation and the speed of rotation should be as high as feasible. A gyroscopic wheel should be well balanced, and mounted to permit rotation at high speed while free to move about any axis.

Elementary Gyroscope.—The ways in which gyroscopic wheels are mounted are various, and depend upon the duties they are to perform. The type illustrated in fig. 1 is the most familiar form for general study. This type of elementary gyroscope is a balanced wheel mounted so as to be free to spin with its axle in any direction, *i.e.*, it has three *degrees of freedom*. The three degrees of freedom of the elementary gyroscope (fig. 1) are the following: (1) The wheel is free to rotate (spin) about its "spinning" axis, the wheel's axle. (2) The wheel (with its axle and axle bearings) is free to rotate about the "vertical" axis, which axis is in the plane of the wheel and intersects the spinning axis at right angles. (3) The wheel (with its axle, axle bearing, vertical axis and vertical axis bearings) is free to rotate about the "horizontal" axis, which axis intersects the vertical axis at right-angles at the intersection with the spinning axis. The spinning and vertical axes are always at right-angles to each other, as are also the horizontal and vertical axes, but the spinning axis may make any angle with the horizontal axis. The spinning axis may also be in any direction horizontally, and therefore in any direction relative to space.

FIG. 2

Gyroscopic Properties and Rigidity.

—All known gyroscopic phenomena and the application of the principles involved are dependent upon two properties of the elementary gyroscope; *viz.*: (1) Rigidity in space (actually *gyroscopic inertia*). (2) Precession.

Rigidity relative to space is illustrated by the following experiments and considerations: On spinning the gyro-wheel in either direction, it will be found to have assumed a rigidity of direction of its axle and plane of rotation relative to space. It can be carried about on its support, which may be turned in any direction, without alteration of the direction of its axis relative to space. If a gyroscope having complete freedom is so made that it can spin continuously and is sufficiently frictionless in its supports, it will, if used in the following manner, demonstrate its gyroscopic inertia, the property referred to as "rigidity in space." If such a gyroscope is set at the earth's equator, with its spinning axis horizontal in the east and west direction (*see* figs. 2 and 3) and is spinning continuously, then the wheel, while spinning, will also apparently rotate about a horizontal axis which is at right-angles to the spinning axis. This apparent rotation will proceed at the rate of one revolution in one day. Actually, however, the gyro spinning axis has remained parallel to its original position in space, though the gyroscope has been carried along with the earth by the revolution of the latter about its polar axis. Thus (fig. 4) at the end of three hours the west end of the axle viewed looking north as above will be depressed 45°, and at the end of six hours it will be vertical (to the surface of the earth), having been carried through a quarter revolution in a quarter of a day. At the end of 12 hours it will again be horizontal but with its ends reversed, as viewed by the observer looking north; but actually the gyro axle will still be parallel to its original position in space and pointing in its original direction in space. At the end of one complete revolution of the earth the original position of the gyro axle is regained.

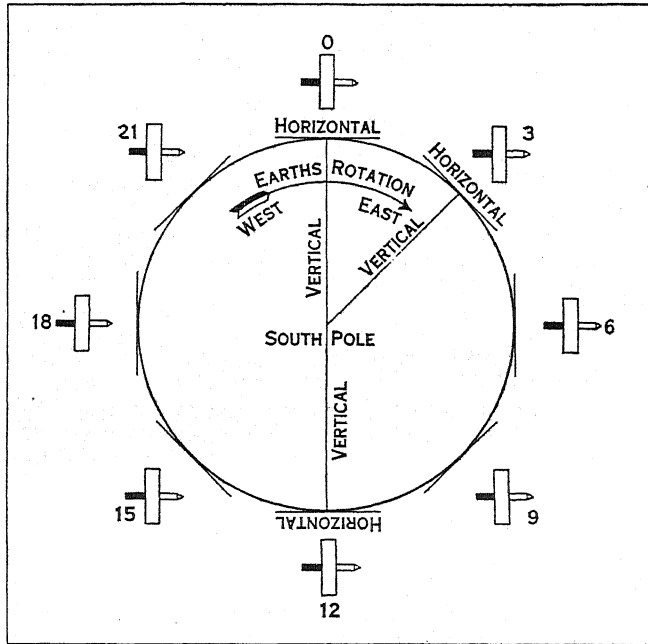

BY COURTESY OF THE SPERRY GYROSCOPE CO.

FIG. 1.—THE MOST FAMILIAR FORM OF ELEMENTARY GYROSCOPE FOR GENERAL STUDY. IT CAN SPIN WITH ITS AXES IN ANY DIRECTION

This and similar gyroscopic phenomena are the result of the action of forces affecting the state of rest and motion of the gyroscope in the manner expressed by Newton's First Law of Motion, which states that every body continues in its state of rest or uniform motion in a straight line, unless it is compelled by forces to change that state. This law, as applied to a rotating wheel, may be expressed by stating that a rotating wheel tends to maintain the direction of its plane of rotation in space and the direction of its axis in space. A gyroscopic wheel at rest, or any balanced mass at rest with corresponding freedom to move, would show similar phenomena when moved about, if there were no friction. Friction cannot be eliminated entirely, but may be

reduced to a minimum by ball-bearing pivots, etc. (see BEARINGS). For a rotating wheel, friction can be reduced to an almost negligible amount in comparison with the forces necessary to disturb the plane of rotation. For a gyroscope with complete freedom, set spinning at either the North or South Pole of the earth, with the gyro axis horizontal, the latter will be at right-angles to the polar axis of the earth. As, however, the spinning gyroscope will maintain the direction of its plane of rotation in space and the direction of its axis in space, though the earth rotates under it, the gyro will have an apparent motion about the polar axis, so that the gyroscope appears to rotate about its vertical axis while spinning about its axle.

The apparent motion will be in a direction counter to the direction of rotation of the earth about its polar axis. The apparent motion of the gyroscope about its vertical axis will therefore appear clockwise as viewed looking toward the earth at the north

BY COURTESY OF THE SPERRY GYROSCOPE CO.

FIG. 3

pole, and counter-clockwise as viewed looking toward the earth at the south pole, the direction of view of the earth's rotation being the reverse at the South Pole to the direction of view at the North Pole. It should be noted that, at the Poles, the apparent rotation is entirely about a vertical axis, but at the equator the apparent rotation is entirely about a horizontal axis. For a gyroscope with complete freedom, set spinning at some intermediate latitude, with the gyro axle horizontal and in the meridian, the gyro axle will neither be parallel to nor at right-angles to the earth's axis, but will be at an angle to it equal to the latitude, and therefore also at the equal angle to a line which passes through the centre of the gyroscope and is parallel to the polar axis of the earth as indicated in fig. 5.

Apparent Rotation.—Rigidity of direction in space, or gyroscopic inertia, will therefore cause the gyro axis apparently to rotate about a line *A-B* (fig. 4), passing through the centre of the gyroscope and parallel to the polar axis of the earth. This apparent movement of the gyro axle, will be with a daily period and will be partly about the vertical line passing through the centre of the gyroscope and the centre of the earth, and partly about the "horizontal" axis of the gyroscope. This "horizontal" axis (see fig. 3) should not be confused with the gyro axis which is in the horizontal position (fig. 4) only momentarily during each day for the conditions assumed. The earth's axis is, for the time, considered as fixed in direction in space and it serves as a convenient base-line from which to observe certain gyroscopic and directional phenomena.

Precession.—The gyroscopic property referred to as *precession*

is displayed by a gyroscope when a force is applied to the gyroscope tending to change the plane of rotation of the spinning wheel. Precession may be defined as follows: when a gyroscope is subjected to a force which tends to alter the direction of its axle in space, the force meets with great resistance, and the gyro-wheel will turn about an axis at right-angles to the axis about which the force was applied, the movement being such as to

BY COURTESY OF THE SPERRY GYROSCOPE CO.

FIG. 4

place the plane and direction of spinning rotation of the wheel coincident with the plane and direction of the force by the shortest path.

This property may be illustrated experimentally. Fig. 5 shows a wheel mounted so as to have three degrees of freedom and, for convenience of experiment, set with its spinning axis horizontal. On spinning the gyroscopic wheel in the direction indicated by the arrow *B* and applying force *F* to turn the gyroscope about the horizontal axis, it will be found that there is a great resistance to the force, and, instead of motion taking place in the direction of the applied force, that the wheel turns around in the direction of the arrow *P* and will continue to turn in that direction during application of the force until the plane of spin of the wheel coincides with the plane of the force. Then the wheel not only

BY COURTESY OF THE SPERRY GYROSCOPE CO.

FIG. 5

ceases to turn in the direction of the arrow *P*, but the resistance to the applied force *F* also ceases, and accordingly the gyro will be turned about its horizontal axis by the force *F*. Furthermore, the wheel will cease turning around in the direction of the arrow *P*, not only when the two planes coincide but also as soon as the application of the force is interrupted, though the axes have not reached a point of coincidence at that time. In other words, not only does precession cease at any stage on removal of the force but the gyroscope offers no further resistance to the impressed force once the plane of spinning rotation becomes coincident with that of the applied force. Reversing the direction of spin and repeating the experiment (fig. 6), similar phenomena

will be exhibited, except that the wheel turns in the opposite direction. This precession is always about an axis at right-angles to the axis of the impressed force.

Continuous Precession.—When the couple acting on the gyro system is arranged in such a way that it and the plane containing

it are caused to rotate with the precession, the latter becomes continuous. This is illustrated in fig. 7, showing a spinning gyro with horizontal axle and with a weight hung at one end of the axle. Instead of turning over under the pull exerted by gravitational force on the weight, as would be the case if the wheel were not spinning, the spinning wheel will turn about its axis, as indicated at *P* in fig. 7. The axis about which the wheel spins is at right angles to the axis of the applied force in the instance illustrated, and tends to set its plane of rotation into coincidence with the plane containing the applied force. As the weight, however, is carried around by the gyro frame, the wheel continues to chase the weight and continuous precession results. Precession will cease immediately upon removal of the weight. Reversal of the direction of spin reverses the direction of the precessional motion. Reversal of the direction of the applied force, by hanging the weight on the other end of the axle, reverses the direction of the precessional motion. The direction of the precessional motion remains unchanged if both direction of spin and direction of applied force are reversed.

PRACTICAL APPLICATIONS

Gyro-compass.—In the case of the gyro-compass (*q.v.*), both the rigidity in space, and the precession characteristics of the gyroscope are utilized, but the sensitive or rotating element is harnessed by the force of gravity so that the spinning axis of the gyro is brought into line with the north-south axis of the earth and is caused to remain there. The gyro-compass is a necessity in naval work where the great masses of iron and steel seriously impair the accuracy of the magnetic compass and where a high degree of accuracy is required for gun fire control. The gyro-compass is also in use in practically every large merchant fleet in the world on account of the safety and added economy of navigation it affords. Vessels ranging from small power yachts to ocean liners use the gyro-compass.

Gyro-stabilizer for Ships.—In order to add materially to the pleasure and comfort of ocean travel, as well as to reduce the stresses and strains imposed on a ship's framework when rolling in a heavy sea, many different forms of apparatus have been devised. The only kind which has hitherto (1928) met with any great degree of success is the gyroscopic stabilizer, developed by Elmer A. Sperry. This stabilizer is a compact unit generally located below decks on the centre-line of the ship. It consists of a rotor of special steel and a supporting casing resting in horizontal "thwartships" gudgeon bearings, so that the rotor axle, when central, is vertical, with the ship on an even keel. The only apparent movement of the stabilizer other than the spinning of its rotor, is a tilting or precessing, fore and aft in the thwartships bearings. In so doing, however, the gyro exerts a righting force against the action of the wave as it tends to roll the vessel over. By dealing with each wave increment individually and by exerting a small counteracting force against it at just the right moment, the gyro-stabilizer quenches the force of each wave and never allows the vessel to build up more than three or four degrees roll.

The Sperry stabilizer is known as the "active" type, for its action is not limited to the rolling of the ship, but is artificially controlled by means of a precession motor which applies, through suitable gearing, an initial push to the gyro which causes it to respond at the very inception of roll. The precession motor is actuated through an electric circuit governed by a small and sensitive control gyro. The latter, by precessing slightly at the first inclination of the vessel to roll, closes a set of contacts which, through relays, starts the precession motor in the proper direction to apply an initial push to the stabilizing gyro. This push overcomes the static friction in the gudgeon bearings of the heavy wheel and allows it to act without delay. Once started, the force of the wave on the ship's hull keeps the big gyro precessing until the wave's energy is spent. The ship has remained upright, and as the wave passes beneath and tends to roll her in the other direction, the entire cycle is reversed, the stabilizing gyro precessing in the opposite direction and preventing the vessel from rolling back again. Conversely, with the active type of gyro-stabilizer,

the vessel may be artificially rolled in smooth water. This may be of considerable value in extricating her from a difficult position, or in working through ice fields. Among the stabilizers that have been built is one for a liner of 18,000 tons displacement. The rotor for this equipment is 13 ft. in diameter and weighs approximately 225,000 pounds. One of the smallest gyroscopic stabilizers built is that of a 65 ft. yacht, the rotor of which is only 28 in. in diameter.

Roll and Pitch Recorder.—This is an instrument to determine the amplitude of a vessel's roll and pitch and the period of these

BY COURTESY OF THE SPERRY GYROSCOPE CO.

FIG. 6

motions. It consists of a small gyroscope with controlling mechanism for two pens, one of which makes a record of the roll, the other of the pitch of the vessel. A sheet of recording paper is automatically drawn under the two pens, and a third operated by clockwork makes marks on the paper at fixed intervals of time. The instrument with its switches, connecting cord, etc., is contained in a box with carrying handle attached. It is designed to operate from the ship's lighting circuit, the rotor of the gyroscope being a self-contained direct current motor with commutator and brushes. The roll and pitch recorder makes use of a gyroscopic pendulum whose natural period is so long that the comparatively short period of the motion of the ship does not affect it. The stable reference plane thus established enables the amplitude of roll and pitch of the vessel to be accurately recorded on the moving strip of paper. The accuracy of this record and its corresponding time interval line enables comparisons to be made of the roll and pitch of a vessel under various conditions of loading, speed and sea. The charts are used by engineers in designing stabilizers to meet the requirements of certain ships, and as records of the operation of stabilizers after they have been installed.

Gyroscopic Track Recorder.—Within more recent years the gyroscope has entered a new field of utility. This was brought about by the advent of the Sperry gyro track recorder, which is used on railroads to determine the condition of the roadbed. In addition to recording differences of elevation of the two rails on both curved and straight sections of the track, accurate records are also made of the magnitude and exact location of rail spreads, rail depressions, the depth of low rail joints, and other inequalities in the roadbed at the time the track is subjected to the actual impact of the car passing over the rails at normal speed. The gyroscope is the only means yet developed of obtaining a stabilized vertical within the car, uninfluenced by the disturbing effects of the train's movements as it rounds a curve or changes its rate of motion. By utilizing the vertical-seeking properties of a pendulum and stabilizing it with a gyroscope, a means is provided for obtaining exact indications of the behaviour of the track as the heavy trucks pass over it.

FIG. 7

Other Uses.—The gyroscope has been applied with considerable success in many other fields. In aviation an automatic pilot has been developed, which embodies one or more gyroscopes and serves to operate the aeroplane's controls automatically. A gyroscopic instrument used in many modern aeroplanes is the *turn and bank indicator* (see *AERIAL NAVIGATION*). The sensitive element consists of a small air-driven gyroscope operated by the vacuum produced by the venturi tube placed in the wind stream. The gyro is only 1½ in. in diameter, weighs 6 oz., and revolves at 5,000 revolutions per minute. It is mounted in such a way that it reacts only to motion about a vertical axis, being unaffected by rolling and pitching.

THE GYROSCOPIC SHIP STABILIZER TO PREVENT THE ROLLING OF OCEAN VESSELS

Sperry gyroscopic ship stabilizer (fig. 1) installed on the "Savarona" (fig. 2), a 294 ft. Diesel yacht of 2,300 tons displacement. This machine is one of the largest of its kind ever made for yachts. The gyro-stabilizer operates under the direction of a small, sensitive control gyroscope mounted

on the corner of the base of main gyro-stabilizer. Both instruments contain rotors or spinning flywheels serving to balance hull of vessel. Control gyroscope responds instantly to slightest roll of ship, transmitting "precession" or counteracting motion to large gyroscope

SPERRY GYROSCOPIC RECORDERS FOR USE ON LAND AND SEA

1. Gyroscopic track recorder: Paper moves, with car recording the cross-level of track, including all irregularities affecting level of car
2. Gyroscopic roll and pitch recorder for ocean vessels. From left to right on chart table are roll recording pen, pitch pen, time pen

The gyro, by precessing in one direction or the other, actuates a pointer which moves over a graduated dial. One of these instruments was used by Lindbergh in his non-stop flight from New York to Paris in 1927.

Gyroscopes are used extensively in naval warfare to control torpedoes. The rotor of one of these instruments is given an initial spin (by means of compressed air) either just before or at the time when the torpedo is leaving the tube. It is designed to revolve at a high rate of speed for about 15 min., or as long as the torpedo continues to move through the water. The "rigidity of space" characteristic of the gyroscope only is employed in this case. The gyroscope, by means of air pressure, controls a small steering engine in the after part of the torpedo which actuates the rudders.

Many other auxiliary instruments, having gyroscopic control have been developed. For example there is, the Sperry *gyro-pilot*, operated electrically from the gyro-compass, which automatically steers all types of vessels with greater precision than a human helmsman and with the use of less rudder. There is the *course recorder*, also operated electrically from the gyro-compass, an instrument which provides a permanent, written record of every lateral movement of a ship's head from the moment the ship leaves the lock until her voyage is completed. (E. A. Sp.)

See R. F. Deimel, *Mechanics of the Gyroscope* (1928).

GYTHIUM, the harbour and arsenal of Sparta (some 30 m. distant), lay at the north-west extremity of the Laconian gulf, in a small fertile plain at the mouth of the Gythius. Its reputed founders were Heracles and Apollo, who frequently appear on its coins. In classical times it was a community of *perioeci*, politically dependent on Sparta. Subsequently it formed the most important of the Eleutherolaconian towns, a group of twenty-four, later eighteen, communities leagued to maintain their autonomy against Sparta and declared free by Augustus. The highest officer of the confederacy was the general.

Pausanias (iii. 21 f.) has a description of the town in the reign of Marcus Aurelius, the agora, the Acropolis, the island of Cranae (Marathonisi) where Paris celebrated his nuptials with Helen, the Migonium or precinct of Aphrodite Migonitis (occupied by the modern town of Marathonisi or Gythium), and the hill Larysium (Koumaro) rising above it. Extant remains are all of Roman date: the theatre and the buildings partially submerged by the sea are noteworthy.

The modern town is a busy port with a good harbour protected by Cranae, now connected by a mole with the mainland: it is the capital of the prefecture (*νομός*) of Laconia with a population (1917) 5,430.

H This letter corresponds to Semitic **ח** (cheth), Greek **Η** (eta). In the eastern Greek alphabet the form with three horizontal bars was in use, but in the Chalcidic the more usual form was **Η**. This form was taken over by the Latins. The Etruscan forms are **𐌕** and **𐌕̄**. In the Umbrian alphabet there was a round form **⊙**. The modern majuscule H is derived directly from the Latin.

The cursive Latin form **h** resembled the modern minuscule, and the uncial form was **h**. Both these forms result from writing the letter without taking pen from paper, the right-hand vertical bar being thus fore-shortened and the horizontal stroke rounded.

From these came the Carolingian **h** and the modern minuscule **h**.

THE DEVELOPMENT OF THE LETTER "H" FROM THE PHOENICIAN THROUGH THE LATIN TO ITS PRESENT FORM

In the eastern Greek alphabet the letter, which in Semitic as well presumably as in the parent alphabet of both Etruscan and Greek, represented an aspirate, was employed for the long open *e*, while in the western it retained its character as an aspirate, standing for the Greek rough breathing, a far weaker sound than the Semitic aspirate. In the early Greek inscriptions from the island of Thera it is used in both capacities. Its employment as a vowel is in conformity with the Greek habit of using letters of the Semitic alphabet which to them were superfluous to express

their vowels which were not written in Semitic. The Greeks probably derived this arrangement from Asia Minor, and they carried it further. The letter passed from the Chalcidic into the Latin with the force of the aspirate, which it still retains. In the Romance languages the sound has disappeared, but the letter remains. (B. F. C. A.)

In music in the German nomenclature, H stands for B natural, while the letter B is used for B flat. This confusing arrangement dates back to earlier centuries when, to get the semitone in the right place (between the 3rd and 4th notes) in the hexachord beginning on F, a new B, half a tone lower than the normal B, was introduced. This lowered B was called B molle (soft) and indicated by a rounded B (*B rotundum*) to distinguish it from the square sign of the natural B (*B quadratum*). B rotundum was later adopted as a general sign in the form of a flat (b) to indicate the lowering of a note by a semitone, while B quadratum became the sign, in the form of a natural (♮), for a note not so lowered; and in this way, from the resemblance of the latter sign to an H, this letter came to be adopted in Germany for the natural or unlowered, B. In other words H is here really an erroneous and misleading form of what was originally a square-shaped B.

HAAG, CARL (1820-1915), a naturalized British painter, court painter to the duke of Saxe-Coburg and Gotha, was born at Erlangen in Bavaria, and trained in the academies at Nuremburg and Munich. He practised first as an illustrator and as a painter, in oil, of portraits and architectural subjects; but after he settled in England in 1847 he devoted himself to water colours. He painted landscapes of Tirolese and Dalmatian scenery, and in Great Britain many pictures of the life of the royal family at Balmoral. Towards the end of his professional career Carl Haag returned to Germany and died there in 1915.

HAAKON (Old Norse *Hákon*), the name of several kings of Norway, of whom the most important are the following:—

HAAKON I., surnamed "the Good" (d. 961), was the youngest son of Harald Haarfager. He was fostered by King Aethelstan of England, who brought him up in the Christian religion, and on the news of his father's death in 933 provided him with ships and men for an expedition against his half-brother Erik, who had been proclaimed king. On his arrival in Norway Haakon gained the support of the landowners by promising to give up the rights of taxation claimed by his father over inherited real property. Erik fled, and was killed a few years later in England. His sons allied themselves with the Danes, but were invariably defeated by Haakon, who was successful in everything he undertook except in his attempt to introduce Christianity, which aroused an opposition he did not feel strong enough to face. He was killed at the battle of Fitje in 961, after a final victory over Erik's sons.

HAAKON IV., surnamed "the Old" (1204-1263), was declared to be the son of Haakon III., who died shortly before the former's birth in 1204. A year later the child was placed under the protection of King Inge, after whose death in 1217 he was chosen king; though until 1223 the church refused to recognize him, on the ground of illegitimacy, and the pope's dispensation for his coronation was not gained until much later. In the earlier part of his reign much of the royal power was in the hands of Earl Skule, who intrigued against the king until 1239, when he proceeded to

open hostility and was put to death. From this time onward Haakon's reign was marked by peace and prosperity, until in 1263 a dispute with the Scottish king concerning the Hebrides, a Norwegian possession, induced Haakon to undertake an expedition to the west of Scotland. A division of his army seems to have repulsed a large Scottish force at Largs (though the later Scottish accounts claim this battle as a victory), and, having won back the Norwegian possessions in Scotland, Haakon was wintering in the Orkneys, when he died on Dec. 15, 1263. A great part of his fleet had been scattered and destroyed by storms. The most important event in his reign was the voluntary submission of the Icelandic commonwealth. Worn out by internal strife fostered by Haakon's emissaries, the Icelandic chiefs acknowledged the Norwegian king as overlord in 1262. Their example was followed by the colony of Greenland.

HAAKON VII. (1872–), the second son of Frederick VIII., king of Denmark, was born on Aug. 3, 1872, and was usually known as Prince Charles of Denmark. When in 1905 Norway decided to separate herself from Sweden the Norwegians offered their crown to Charles, who accepted it and took the name of Haakon VII., being crowned at Trondhjem in June 1906. The king married Maud, youngest daughter of Edward VII., king of Great Britain and Ireland, their son, Prince Olav, being born in 1903.

HAARLEM, a town of Holland in the province of North Holland, on the Spaarne, having a junction station 11 m. W. of Amsterdam by rail. It is connected by electric and steam tramways with Zandvoort, Leiden, Amsterdam and Alkmaar. Pop. (1926) 111,242.

Haarlem, a prosperous place in the middle of the 12th century, received its first town charter from William II., count of Holland and king of the Romans, in 1245. It played a considerable part in the wars of Holland with the Frisians. In 1492 it was captured by the insurgent peasants of North Holland and was re-taken by the imperial stadholder, and deprived of its privileges. In 1572 Haarlem joined the revolt of the Netherlands against Spain, but in July 1573, after a seven months' siege, was forced to surrender to Alva's son Frederick, who exacted terrible vengeance. In 1577 it was re-captured by William of Orange and permanently incorporated in the United Netherlands.

Haarlem is the seat of the governor of the province of North Holland, and of a Roman Catholic and a Jansenist bishopric. It is a typical Dutch town, with numerous narrow canals and gabled houses. Of the ancient city gates the Spaarnewouder or Amsterdam gate alone remains. In the Frederiks Park is a pump-room supplied with a powerful chalybeate water from a spring, in the Haarlemmer Polder. In the central market place are the old Flishers' Hall, built by Lieven de Key in 1603, and now containing the archives, the town hall, the old Stadsdoelen, where the burghesses met in arms and the *Groote Kerk* (Great Church). This last, dedicated to St. Bavo, dates from the late 15th and early 16th centuries. Its great length (460 ft.) and the height and steepness of its vaulted cedar-wood roof (1538) are very impressive. The choir-stalls and screen (1510) are finely carved, and of further interest are the ancient pulpit sounding-board (1432), some old stained glass, and the small models of ships, copies dating from 1638 of yet earlier models originally presented by the Dutch-Swedish Trading Company. The church organ, constructed in 1738, was long considered the largest and finest in existence. In the belfry are the *damiaatjes*, small bells presented to the town, according to tradition, by William I., count of Holland (d. 1222), the crusader. The town hall was originally a palace of the counts of Holland, begun in the 12th century, and some old 13th-century beams still remain; but the building was remodelled in the beginning of the 17th century. It contains a collection of antiquities and a picture gallery celebrated for its fine collection of paintings by Frans Hals. The town library contains several *incunabula* and a collection of early Dutch literature. At the head of the scientific institutions of Haarlem may be placed the Dutch Society of Sciences (*Hollandsche Maatschappij van Wetenschappen*), founded in 1752. Besides these there are the old weigh-house (1598) and the orphanage for girls (1608), originally an almshouse for old men, both built by the architect Lieven de Key

of Ghent.

The staple industries of Haarlem have been greatly modified in the course of time. Cloth weaving and brewing declined in the beginning of the 16th century. A century later, silk, lace and damask weaving were introduced by French refugees, and became very important industries; but about the close of the 18th century this remarkable prosperity had also come to an end, and it was not till after 1830 that Haarlem began to develop the manufactures in which it is now chiefly engaged. Cotton manufacture, dyeing, printing, bleaching, brewing, making of paint, type-founding, and the manufacture of tram and railway carriages are among the more important of its industries. One of the printing establishments has the reputation of being the oldest in the Netherlands, and publishes the oldest Dutch paper, *De Oprechte Haarlemmer Courant*. Market-gardening, especially horticulture, is extensively practised in the vicinity, so that Haarlem is the seat of a large trade in Dutch bulbs, especially hyacinths, tulips, fritillaries, spiraeas and japonicas.

HAARLEM LAKE (Dutch *Haarlemmer Meer*), a commune of the province of North Holland, constituted by the law of July 16, 1855. It has an area of about 46,000 ac., and its population increased from 7,237 in 1860 to 16,621 in 1900. The commune was formerly a lake, which is said to have been a relic of a northern arm of the Rhine which passed through the district in the time of the Romans. In 1531 the Haarlemmer Meer and three smaller sheets of water in its vicinity had a united area of about 14,000 acres. The four lakes were formed into one by successive inundations and by 1647 the new Haarlem Lake had an area of about 37,000 acres, which a century later had increased to over 42,000 acres. As early as 1643 Jan Adriaanszoon Leeghwater proposed to endike and drain the lake; and similar schemes were brought forward from time to time. A furious hurricane in Nov. 1836 drove the waters as far as the gates of Amsterdam, and another on Christmas Day sent them in the opposite direction to submerge the streets of Leiden. In Aug. 1837 the king appointed a royal commission of inquiry; the scheme proposed by the commission received the sanction of the Second Chamber in March 1839, and in the following May the work was begun. A canal was first dug round the lake for the reception of the water and the accommodation of the traffic which had previously been carried on. As the water from the lake had no natural outfall pumping by steam-engines began in 1848, and the lake was dry by July 1852. The whole area of 42,096 ac. recovered from the waters brought in about £780,000, exactly covering the cost of the enterprise; so that the actual cost to the nation was only the amount of the interest on the capital. The soil is of various kinds, loam, clay, sand and peat; most of it is fertile, though in the lower portions there are barren patches where the scanty vegetation is covered with an ochreous deposit. Mineral springs occur containing a very high percentage of common salt; and a company was formed for working them. Corn, seeds, cattle, butter and cheese are the principal produce. Hoofddorp, Venneperdorp or Nieuw Vennepe, Abbenes and the vicinities of the pumping-stations are the spots where the population has clustered most thickly.

HAAS, JOHANNES HUBERTUS LEONHARDUS DE (1832–1908), Dutch animal painter, was born at Hedel in North Brabant on March 25, 1832. He was a pupil of Van Oos at Haarlem, and settled in Brussels in 1857. His pictures of cattle grazing in flat pastureland under soft, dull skies are in the true Low Country tradition. He died at Königswinter on Aug. 4, 1908.

HAASE, FRIEDRICH (1827–1911), German actor, was born on Nov. 1, 1827, in Berlin, the son of a valet to King Frederick William IV., who became his godfather. He made his first appearance on the stage in 1846 in Weimar, afterwards acting at Prague (1849–51) and Karlsruhe (1852–55). He played in St. Petersburg, 1860–66, then was manager of the court theatre in Coburg, and in 1869 (and again in 1882–83) visited the United States. He was manager of the Stadt Theater in Leipzig from 1870–6, when he removed to Berlin, where he founded and managed Deutsches Theater. He retired from the stage in 1898. Haase's aristocratic appearance and elegant manner fitted him

specially to play high comedy parts. He died in Berlin on March 17, 1911.

See Simon, *Friedrich Haase* (Berlin, 1898).

HAASE, FRIEDRICH GOTTLÖB (1808-1867), German classical scholar, was born at Magdeburg on Jan. 4, 1808, and died on Aug. 16, 1867, at Breslau, where he had been professor since 1840. He was one of the most successful teachers of his day.

He edited several classic authors: Xenophon (*Λακεδαιμονίων πολιτεία*, 1833); Thucydides (1830); Velleius Paterculus (1858); Seneca the philosopher (2nd ed., 1872, not yet superseded); and Tacitus (1855), the introduction to which is a masterful piece of Latinity. His *Vorlesungen über lateinische Sprachwissenschaft* was published after his death by F. A. Eckstein and H. Peter (1874-80). See C. Bursian, *Geschichte der klassischen Philologie in Deutschland* (1883); G. Fickert, *Friderici Haasii memoria* (1868), with a list of works; T. Oelsner in *Rubenzahl* (*Schlesische Provinzialblätter*), vii. Heft 3 (Breslau, 1868).

HAASE, HUGO (1863-1919), German Socialist leader, was born on Sept. 29, 1863, at Allenstein in East Prussia. At the outbreak of the World War he was parliamentary leader of the Social Democratic party in the Reichstag. As early as 1915 he demanded the cessation of the war, and in 1916 became the leader of the dissentients. The formal constitution of the new Independent Socialist party, of which he was the head, took place at a conference held at Gotha in 1917. He exercised a moderating influence upon the extreme section of the Independents, who at a later date (1920) joined the Communists. He was one of the commission of six who conducted the Government of the German Reich, in the name of the people, from Nov. 9 to Dec. 29, 1918. Faithful to the principles of his party he declined to take part in subsequent administrations which included representatives of the bourgeoisie. Haase died on Nov. 7, 1919, from wounds received in an attempt upon his life by a personal opponent while he was entering the Reichstag building.

HAAST, SIR JOHANN FRANZ JULIUS VON (1824-1887), German and British geologist, was born at Bonn on May 1, 1824. In 1858 he started for New Zealand to report on immigration possibilities. He assisted Hochstetter in his preliminary geological survey. The governments of Nelson and Canterbury then employed Haast to investigate the geology of those districts. He discovered gold and coal in Nelson, and carried on important researches with reference to the occurrence of *Dinornis* and other extinct wingless birds (Moas). His *Geology of the Provinces of Canterbury and Westland, N.Z.*, was published in 1879. He was the founder and director of the Canterbury museum at Christchurch. He was surveyor-general of Canterbury from 1861 to 1871, and professor of geology at Canterbury college. He was elected F.R.S. in 1867; and he was knighted in 1887. He died at Wellington, N.Z., on Aug. 15, 1887.

HABABS, a nomadic pastoral people of Hamitic stock, living in the coast region north-west of Massawa. Physically they are Beja, by language and traditions Abyssinians. They were Christians until the 19th century, but are now Mohammedans. Their sole wealth consists in cattle.

HABAKKUK, the name borne by the eighth book of the Old Testament "Minor Prophets." Nothing is known of its writer, save what may be inferred from the book; legend connects him with Daniel ("Bel and the Dragon"). The book falls into three obvious parts, viz. (1) a dialogue between the prophet and God (i. 2-ii. 4); (2) a series of five woes pronounced on wickedness (ii. 5-ii. 20); (3) a poem describing the triumphant manifestation of God (iii.). There is considerable difficulty in regard to the interpretation of (1), on which that of (2) will turn; while (3) forms an independent section, to be considered separately.

In the dialogue the prophet cries to God against continued violence and injustice, though it is not clear whether this is done *within* or *to* Israel (i. 2-4). The Divine answer declares that God raises up the Chaldaeans, whose formidable resources are invincible (i. 5-11). The prophet thereupon calls God's attention to the tyranny which He apparently allows to triumph and declares his purpose to wait till an answer is given to his complaint (i. 12-ii. 1). God answers by demanding patience, and by declaring that the righteous shall live by his faithfulness (ii. 2-4).

The interpretation of this dialogue which first suggests itself is

that the prophet is referring to wickedness *within* the nation, which is to be punished by the Chaldaeans (*i.e.*, the Babylonians) as a Divine instrument; in the process the tyranny of the instrument itself calls for punishment, which the prophet is bidden to await in patient fidelity. On this view of the dialogue the subsequent woes will be pronounced against the Babylonians, and the date assigned to the prophecy will be about 600 B.C., *i.e.*, soon after the battle of Carchemish (605 B.C.) when the Babylonian victory over Egypt inaugurated a period of Babylonian supremacy which lasted till Babylon was overthrown by Cyrus in 538 B.C. It is strange, however, that the prophet should pass so abruptly in a single dialogue from the wickedness of Israel to that of Babylon, thus destroying his primary emphasis; moreover, the wickedness of i. 2 *seq.* and of i. 12 *seq.* seems identical. Possibly i. 5-11 is a misplaced earlier prophecy, whilst i. 2-4, 12 *seq.* refers to the Babylonian oppression of Israel (Giesebrecht, Nowack, Wellhausen), or it is a part of the Divine answer, following ii. 4, which would make the Babylonians the Divine instrument for punishing Assyrian tyranny (Budde). Duhm's theory (followed by Sellin) refers the whole book to the time of Alexander the Great, by the violent emendation of "Chaldaeans" to "Chittim" (= Greeks).

The most striking characteristic of the poem (iii.) lies in the superscription ("A prayer of Habakkuk the prophet, set to Shigionoth"), the subscription ("For the chief musician, on my stringed instruments"), and the insertion of the musical term "Selah" in three places (v. 3, 9, 13). These liturgical notes make extremely probable the supposition that the poem has been taken from some collection like that of our present book of Psalms. The poem begins with a prayer that God will renew the historic manifestation of the exodus, which inaugurated the national history and faith; a thunderstorm moving up from the south is then described, in which God is revealed (3-7); it is asked whether this manifestation, whose course is further described, is against nature only (8-11); the answer is given that it is for the salvation of Israel against its wicked foes (12-15); the poet describes the effect in terror upon himself (16) and declares his confidence in God, even in utter agricultural adversity (17-19). There is nothing in this fine poem to connect it with the conception of the Chaldaeans as a Divine instrument. It is the nation that speaks through the poet (*cf.* v. 14), but at what period of its post-exilic history we have no means of inferring.

In regard to the theological teaching of the book: (1) the poem (iii.), though possibly latest in date, claims first consideration, because it avowedly moves in the circle of primitive ideas, and supplants a Divine intervention, a direct and immediate manifestation of the transcendent God. He is conceived as controlling or overcoming the forces of nature; and though an earlier mythology has supplied some of the ideas, yet, as with the opening chapters of Genesis, they are transfigured by the moral purpose which animates them, the purpose to subdue all things that could frustrate the destiny of God's anointed (v. 13). The closing verses strike that deep note of absolute dependence on God, which is the glory of the religion of the Old Testament and its chief contribution to the spirit of the Gospels. (2) The prophecy of the Chaldaeans as the instruments of the Divine purpose involves a different, yet related, conception of the Divine providence. The philosophy of history, by which Hebrew prophets could read a deep moral significance into national disaster, and turn the flank of resistless attack, became one of the most important elements in the nation's faith. If the world powers were hard as flint in their dealings with Israel, the people of God were steel to such moral endurance that each clash of their successive onsets kindled some new flame of devotion. Through the Chaldaeans, God worked a work which required centuries of life and literature to disclose its fulness (i. 5). (3) When we turn from this view of the Chaldaeans to the denunciation of their tyranny in "taunt songs" (ii. 5-20), we have simply a practical application of the doctrine of Divine government. God, being what He is, at once moral and all powerful, the immoral life is doomed to overthrow, whether the immorality consist in grasping rapacity, proud self-aggrandizement, cruel exaction, exulting triumph or senseless idolatry. (4) Yet, because the doom so often tarries, there arises the problem of the suffer-

ing of the innocent and the upright. How can God look down with tolerance that seems favour on so much that conflicts with His declared will and character? This is the great problem of Israel, finding its supreme expression for all time in the book of Job (*q.v.*). In that book the solution of the problem of innocent suffering lies hidden from the sufferer, even to the end, for he is not admitted with the reader to the secret of the prologue; it is the practical solution of faithfulness resting on faith which is offered to us. So here, with the principle of ii. 4, "the righteous shall live by his faithfulness." The different application of these words in the New Testament to "faith" is well known (Rom. i. 17; Gal. iii. 11; Heb. x. 38) though the difference is apt to be exaggerated by those who forget how much of the element of "faithfulness" lies in Paul's conception of "faith." In G. A. Smith's words, "as Paul's adaptation, 'the just shall live by faith,' has become the motto of evangelical Christianity, so we may say that Habakkuk's original of it has been the motto and the fame of Judaism: 'the righteous shall live by his faithfulness.'"

BIBLIOGRAPHY.—There are German commentaries by Nowack (1897), Wellhausen (1898), Marti (1904), Duhm (1906), and Sellin (1922); one in French by Van Hoonacker (1908), and English by Davidson *Cambridge Bible* (1896); G. A. Smith, *Expositor's Bible* (1898); Driver, *Century Bible* (1906); G. G. V. Stonehouse (1911); W. H. Ward, *International Critical Commentary* (1912); A. R. Gordon, *Peake's Commentary* (1919); of which Driver's is the best.

HABEAS CORPUS, in law, a writ issued by a judge or court of justice, commanding the person to whom it is directed to bring the body of a person in his custody before that or some other court for a specified purpose.

There are various forms of the writ, of which the most famous is that known as *habeas corpus ad subiciendum*, the well-established remedy for violation of personal liberty. This is now the only important form of writ though there were originally many others. From the earliest records of the English law no free man could be detained in custody except on a criminal charge or conviction or for a civil debt while the writ is a remedial mandatory writ—"of right," it is not "of course," and is granted only on application to the High Court or a judge thereof, supported by a sworn statement of facts setting up at least a probable case of illegal confinement. It is addressed to the person in whose custody another is detained, and commands him to bring his prisoner before the court immediately after the receipt of the writ, together with the day and cause of his being taken and detained, to undergo and receive (*ad subiciendum et recipiendum*) whatsoever the court awarding the writ "may consider of concerning him in that behalf."

Writs of *habeas corpus* were issued before the Great Charter. The writ *de odio et atia* was used as early as the 12th century to prevent imprisonment on vexatious appeals of felony, and this writ is specifically mentioned in Article 36 of Magna Carta which provides that it shall issue gratuitously, and "not be refused." It played an important part in enabling a person to avoid trial by battle and obtain trial by jury. In the case of imprisonment on accusation of crime the writ issued from the court of king's bench (or from the chancery), and on its return the court judged of the legality of the imprisonment, and discharged the prisoner or admitted him to bail or remanded him to his former custody according to the result of the examination.

By the time of Charles I. the writ was fully established as the appropriate process for checking illegal imprisonment by inferior courts or by public officials. But it acquired its full and present constitutional importance by legislation.

In Darnel's case (1627) the judges held that the command of the king was a sufficient answer to a writ of *habeas corpus*. The House of Commons thereupon passed resolutions to the contrary, and after a conference with the House of Lords the measure known as the Petition of Right was passed (1627, 3 Car. I. c. i.) which, *inter alia*, recited (s. 5) that, contrary to the Great Charter and the good laws and statutes of the realm, divers of the king's subjects had of late been imprisoned without any cause shown,

and when they were brought up on *habeas corpus ad subiciendum*, and no cause was shown other than the special command of the king signified by the privy council, were nevertheless remanded to prison, and enacted "that no freeman in any such manner as is before mentioned be imprisoned or detained." By the Act of 1641 abolishing the Star Chamber, the right to a *habeas corpus* was given to test the legality of commitments by command or warrant of the king or the privy council.

The Act of 1679.—The reign of Charles II. was marked by further progress towards securing the freedom of the subject from wrongful imprisonment. Lord Clarendon was impeached, *inter alia*, for causing many persons to be imprisoned against law and to be conveyed in custody to places outside England.

Though the authority of the courts had been strengthened it was still rendered insufficient by reason of the insecurity of judicial tenure, the fact that only the chancellor (a political as well as a legal officer) and the court of king's bench had undoubted right to issue the writ, and the inability or hesitation of the competent judges to issue the writ except during the legal term, which did not cover more than half the year. A series of bills was passed through the Commons between 1668 and 1675, only to be rejected by the other House. In Jenkes's case (1676), Lord Chancellor Nottingham refused to issue the writ in vacation in a case in which a man had been committed by the king in council for a speech at Guildhall, and could get neither bail nor trial. In 1679, but rather in consequence of Lord Clarendon's arbitrary proceedings than of Jenkes's case, a fresh bill was introduced which passed both Houses and became the famous Habeas Corpus Act of 1679 (31 Car. II. c. 2). The passing of the act was largely due to the experience and energy of Lord Shaftesbury, after whom it was for some time called. The act, while a most important landmark in the constitutional history of England, in no sense creates any right to personal freedom, but is essentially a procedure act for improving the legal mechanism by means of which that acknowledged right may be enforced. It declares no principles and defines no rights, but is for practical purposes worth 100 articles guaranteeing constitutional liberty.

In the manner characteristic of English legislation the act is limited to the particular grievances immediately in view and is limited to imprisonment for criminal or supposed criminal matters, leaving untouched imprisonment on civil process or by private persons. It enacts in substance as follows: (1) When a writ of *habeas corpus* is directed to a sheriff or other person in charge of a prisoner, he must within 3, 10 or 20 days, according to the distance of the place of commitment, bring the body of his prisoner to the court, with the true cause of his detainer or imprisonment—unless the commitment was for treason or felony plainly expressed in the warrant of commitment. (2) If any person be committed for any crime—unless for treason or felony plainly expressed in the warrant—it shall be lawful for such person or persons (other than persons convicted or in execution by legal process) *in time of vacation*, to appeal to the lord chancellor as a judge, who shall issue a *habeas corpus* returnable immediately, and on the return thereof shall discharge the prisoner on giving security for his appearance before the proper court, unless the party so committed is detained upon a legal process or under a justice's warrant for a non-bailable offence. Persons neglecting for two terms to pray for a *habeas corpus* shall have none in vacation. (3) Persons set at large on *habeas corpus* shall not be recommitted for the same offence unless by the legal order and process of the court having cognizance of the case. (4) A person committed to prison for treason or felony shall, if he requires it, in the first week of the next term or the first day of the next session of oyer and terminer, be indicted in that term or session or else admitted to bail, unless it appears on affidavit that the witnesses for the Crown are not ready; and if he is not indicted and tried in the second term or session after commitment, or if after trial he is acquitted, he shall be discharged from imprisonment. (5) No inhabitant of England (except persons contracting, or, after conviction for felony, electing to be transported) shall be sent prisoner to Scotland,

Ireland, Jersey, etc., or any place beyond the seas. Stringent penalties are provided for offences against the act.

A judge delaying *habeas corpus* forfeits £500 to the party aggrieved. Illegal imprisonment beyond seas renders the offender liable in an action by the injured party to treble costs and damages to the extent of not less than £500, besides subjecting him to the penalties of *praemunire* and to other disabilities. "The great rank of those who were likely to offend against this part of the statute was," says Hallam, "the cause of this unusual severity." Indeed as early as 1591 the judges had complained of the difficulty of enforcing the writ in the case of imprisonment at the instance of magnates of the realm. The effect of the act was to impose upon the judges under severe sanction the duty of protecting personal liberty in the case of criminal charges and of securing speedy trial upon such charges when legally framed; and the improvement of their tenure of office at the revolution, coupled with the veto put by the Bill of Rights on excessive bail, gave the judiciary the independence and authority necessary to enable them to keep the executive within the law and to restrain administrative development of the scope or penalties of the criminal law; and this power of the judiciary to control the executive, coupled with the limitations on the right to set up "Act of State" as an excuse for infringing individual liberty is the special characteristic of English constitutional law.

The *habeas corpus ad subiiciendum* was sometimes used in cases of illegal detention in private custody. In 1758 questions arose as to its application to persons in naval or military custody, including pressed men, which led to the introduction of a bill in parliament and to the consultation by the House of Lords of the judges. (See Wilmot's *Opinions*, p. 77.) In the same year the writ was used to release the wife of Earl Ferrers from his custody and maltreatment. But perhaps the most interesting instance of that period is the case of the negro Somerset (1771), who was released from a claim to hold him as a slave in England.

The Act of 1816 (56 Geo. III. c. 100), does not touch cases covered by the Act of 1679. The object of it was to deal with cases of persons unlawfully detained in private custody. It enacts (1) that a writ of *habeas corpus* shall be issued in vacation time in favour of a person restrained of his liberty otherwise than for some criminal or supposed criminal matter (except persons imprisoned for debt or by civil process); (2) that though the return to the writ be good and sufficient in law, the judge shall examine into the truth of the facts set forth in such return, and if they appear doubtful the prisoner shall be bailed; (3) that the writ shall run to any port, harbour, road, creek or bay on the coast of England, although not within the body of any county. The last clause was intended to meet doubts on the applicability of *habeas corpus* in cases of illegal detention on board ship.

It will appear from the foregoing statement that the issue and enforcement of the writ rests on the common law as strengthened by the acts of 1627, 1640, 1679 and 1816, and subject also to the regulations as to procedure contained in the *Crown Office Rules*, 1906. The effect of the statutes is to keep the courts always open for the issue of the writ. It is available to put an end to all forms of illegal detention in public or private custody. In the case of the Canadian prisoners (1839) it was used to obtain the release of persons sentenced in Canada for participating in the rebellion of 1837, who were being conveyed throughout England in custody on their way to imprisonment in another part of the empire, and it is matter of frequent experience for the courts to review the legality of commitments under the Extradition Acts and the Fugitive Offenders Act 1881, of fugitives from the justice of a foreign State or parts of the king's dominions outside the British Isles.

Suspension of the Act.—In times of public danger it has occasionally been thought necessary to "suspend" the Habeas Corpus Act, 1679, by special and temporary legislation. This was done in 1794 (by an act annually renewed until 1801) and again in 1817, as to persons arrested and detained by his majesty for conspiring against his person and Government. The same course was adopted in Ireland in 1866 during a Fenian rising. It has been the practice to make such acts annual and to follow

their expiration by an act of indemnity. In cases where martial law exists the use of the writ is *ex hypothesi* suspended during conditions amounting to a state of war within the realm or the British possession affected (e.g., the Cape Colony and Natal during the South African War), and it would seem that the acts of courts martial during the period are not the subject of review by the ordinary courts. The so-called "suspension of the Habeas Corpus Act" bears a certain similarity to what is called in Europe "suspending the constitutional guarantees" or "proclaiming a state of siege," but "is not in reality more than suspension of one particular remedy for the protection of personal freedom."

A principle of the highest importance to the liberty of the subject was laid down by the House of Lords in the case of *Cox v. Hakes* (1890), 15 A.C. 506, and further extended in the leading case of *Ex parte Art O'Brien* (1923), A.C. 603. This principle is that an appeal against the refusal of the writ may be taken by the applicant right up to the House of Lords, but that an appeal by the Crown against the grant of the writ by the divisional court cannot be taken any further. In other words, once the writ is granted, the Crown cannot delay its operation or keep the applicant in custody by attempting to prosecute an appeal. Furthermore it has been decided that it is no answer to the writ to plead that the person detained is no longer in the actual physical custody of the defendant; for example, mere power or control over a child is sufficient to justify the issue of the writ (*Barnardo v. Ford*, 1892, A.C. 326).

Ireland.—The common law of Ireland as to the writs of *habeas corpus* is the same as that in England. The writ has in past times been issued from the English court of king's bench into Ireland; but does not now so issue. The acts of 1803 and 1816 already mentioned apply to Ireland. The Petition of Right is not in terms applicable to Ireland. The Habeas Corpus Act 1679 does not apply to Ireland; but its equivalent is supplied by an act of 1781-82 of the Irish parliament (21 and 22 Geo. III. c. 11). Since the establishment of the Irish Free State, an appeal against the refusal of the writ does not lie to the House of Lords but to the judicial committee of the privy council.

Scotland.—The writ of *habeas corpus* is unknown to Scots law, nor will it issue from English courts into Scotland. Under a Scots Act of 1701 (c. 6) provision is made for preventing wrongous imprisonment and against undue delay in trials. It was applied to treason felony in 1848. The right to speedy trial is now regulated by s. 43 of the Criminal Procedure Scotland Act 1887. These enactments are as to Scotland equivalent to the English Act of 1679. Under the Court of Exchequer Scotland Act 1856 (19 and 20 V. c. 56) provision is made for bringing before the court of session persons and proceedings before inferior courts and public officers—which is analogous to the powers to issue *habeas corpus* in such cases out of the English court of exchequer (now the revenue side of the king's bench division).

British Possessions.—The Act of 1679 expressly applies to Wales, Berwick-on-Tweed, Jersey and Guernsey, and the Act of 1816 also extends to the Isle of Man. The court of king's bench has also issued the writ to the king's foreign dominions beyond seas, e.g., to St. Helena, and so late as 1861 to Canada (Anderson's case 1861, 30 L.J.Q.B. 129). In consequence of the last decision it was provided by the Habeas Corpus Act 1862 that no writ of *habeas corpus* should issue out of England by authority of any court or judge "into any colony or foreign dominion of the Crown where the Crown has a lawfully established court of justice having authority to grant or issue the writ and to ensure its due execution in the 'colony' or dominion" (25 and 26 V. c. 20). The expression "foreign dominion" is meant to apply to places outside the British Isles, and does not include the Isle of Man or the Channel islands. (See *re Brown*, 1864, 33 L.J.Q.B. 193.) It does not apply to British protectorates because they are not "dominions" of the Crown (*R. v. Crewe*, 1910, 2 K.B. 576). But the writ runs everywhere within the king's territorial dominions. Wherever, as is usually the case, the High Court of a colony or of a province of British India is vested with the same jurisdiction as the king's bench, that court has power to issue

the writ. An appeal from a refusal of the writ may be made to the judicial committee of the privy council. (W. F. C.; X.)

United States.—The common law of *habeas corpus* was inherited as part of the common law of the American States. The Federal Government as well as the States have founded their procedure upon the principles set forth in the Act of 1679, most States specifically adopting its features by statutory enactment. The writ, as under the English system, is available to contest detention by public or private authority. The power of the court issuing it extends only to inquire into the jurisdiction of the court, administrative tribunal, or person detaining the prisoner, the legal sufficiency of the proceedings taken against him, or the validity of the judgment or order of commitment. No State or Federal court can issue the writ beyond the territorial limits of its jurisdiction. The esteem with which the writ is regarded is illustrated by the embodiment of the provision in the Federal Constitution as well as in the Constitutions of most States that the privilege of the writ "shall not be suspended unless when in cases of rebellion or invasion the public safety may require it." It is generally thought that the power to suspend the writ is vested in the legislative rather than the executive department of government. Acting under such a theory during the Civil War, Congress in 1863 granted the president the power of suspension whenever in his judgment the public safety demanded it. The proper exercise of such judgment by the president was held by the Supreme Court in *Milligan's Case* (4 Wall. 2) to be subject to judicial review. In instances State supreme courts have regarded the privilege suspended by the State executives' proclamation that an insurrection existed in specified territory.

State courts have no power to issue the writ for the discharge of persons held under claim or colour of authority of any officer or court of the United States inasmuch as the Federal Government when acting within its sphere is supreme. Originally U.S. courts could not issue the writ to inquire into the cause of commitment by State courts. In 1833, however, due to the nullification movement in South Carolina resulting in resistance to the enforcement of Federal revenue laws, Congress extended the authority of the Federal courts to inquire into any commitment for an act done in pursuance of a law of or authority under the United States. During the controversy over the Canadian boundary in 1842 this power was extended to authorize inquiry into the commitment of any foreign citizen for an act done under authority of a foreign State whose validity depended upon international law. In 1847 the power was again extended to all cases where a person was restrained of liberty in violation of the Constitution, laws or treaties of the United States. This, however, does not permit the Federal courts to obstruct the administration of justice in State courts whenever the accused claims that he is restrained in violation of a Federal right. The State courts being themselves bound by the U.S. Constitution, laws and treaties as the "supreme law of the land" can ordinarily be entrusted to determine the Federal right, and in case the determination by contrary to the accused's contention he may resort by writ of error or *certiorari* to the U.S. Supreme Court. It is thus only in cases of peculiar urgency that the Federal court will interfere in the first instance by *habeas corpus*. Such interference being an extremely delicate matter the Supreme Court has limited the issuance of *habeas corpus* to cases that concerned the authority or operations of the Federal Government, its obligations under international law to other nations or the vindication of a fundamental right in danger of violation before resort may be had to usual methods of appeal.

The various States have divergent views as to the accused's right of appeal from an order denying the issuance of *habeas corpus*. The right where denied by judicial decision has commonly been granted by statute. It is also customary to provide by statute for a similar right of appeal on the part of the State. The original jurisdiction of the U.S. Supreme Court being limited by the Constitution, it cannot issue the writ as an original matter except in cases within that jurisdiction. But in exercise of its appellate jurisdiction it may issue the writ to inquire into the validity of a detention under the authority of an inferior court to determine whether such court has acted without jurisdiction or exceeded its

authority.

(J. M. LA.)

HABENARIA, a genus of plants of the orchid family (Orchidaceae), comprising in its most inclusive sense some 500 temperate and tropical species, of which the frog orchis (*H. viridis*), scented orchis (*H. conopsea*) and butterfly orchis (*H. bifolia*) are native to the British Isles. In North America some 40 species occur, among which are the purple-fringed orchis (*H. psychodes*), the white-fringed orchis (*H. blephariglottis*), the ragged orchis (*H. lacera*), the prairie fringed orchis (*H. leucophaea*), the yellow-fringed orchis (*H. ciliaris*), the white bog orchis (*H. dilatata*), the round-leaved orchis (*H. orbiculata*), the slender white orchis (*H. elegans*) and the western green orchis (*H. unalaschensis*). (See ORCHIDS.)

HABER, FRITZ (1868–), German chemist, was born in Breslau on Dec. 9, 1868. He studied at the universities of Berlin and Heidelberg and at the technical high schools at Charlottenburg and Karlsruhe. He was then appointed staff professor at Berlin university and afterwards became director of the Kaiser Wilhelm institute for physical chemistry and electrochemistry. He made a special study of thermodynamic technical gas reactions, and also made experiments in connection with the synthesis of ammonia (*q.v.*) and the influence of very high pressures and high temperatures. During the World War he studied the gases used in warfare and their effective frustration by gas masks and chemical means. He conducted particularly important researches in collaboration with Bosch, which led to the establishment of the Haber-Bosch method for the production of ammonia from atmospheric nitrogen. (See NITROGEN, FIXATION OF.) On the purely chemical side Haber made a thorough study of the electrolytic reduction of nitrobenzene under various conditions, and has carried out other electrochemical investigations.

His works include *Grundriss der technische Elektrochemie* (1898); *Thermodynamik technische Gasreaktionen* (1905; English edition, 1908); *Beitrag zur Kenntnis der Metalle* (1919); *Über die Synthese des Ammoniaks: Die Chemie im Kriege* (1922); *Fünf Vorträge aus den Jahren 1920–23: Über die Herstellung des Ammoniaks aus Stickstoff und Wasserstoff* (1924).

HABERDASHER. A tradesman who sells by retail small articles used in the making or wearing of dress, such as sewing cottons or silks, tapes, buttons, pins and needles, and the like. The sale of such articles is not generally carried on alone, and a "haberdashery counter" usually forms a department of drapers' shops. The word is of obscure origin. The Haberdashers' company is one of the greater Livery companies of the City of London. Originally a branch of the mercers, the fraternity took over the selling of "small wares," which included not only articles similar to those sold as "haberdashery" now, but such things as gloves, daggers, glass, pens, lanterns, mousetraps, and the like. They were thus on this side connected with Milliners. On the other hand there was early a fusion with the old gild of the "Hurers," or cap makers, and the hatters, and by the reign of Henry VII. the amalgamation was complete. There were long recognized two branches of haberdashers, the haberdashers of "small wares," and haberdashers of hats (see LIVERY COMPANIES).

HABERL, FRANZ XAVER (1840–1910), German musician and writer on music, was born at Ober Ellenbach, Bavaria, on Apr. 12, 1840. He was educated and ordained at Passau, and in 1862 was appointed Kapellmeister of the cathedral and musical director of the two seminaries. From 1867–1871 he was in Rome. He then settled at Regensburg, where he established the school of ecclesiastical music. In 1879 he became honorary canon of the cathedral of Palestrina and founded the Palestrina Society. He died at Regensburg on Sept. 5, 1910, having been domestic prelate to the Pope since 1907. Haberl's research in 16th century music is of cardinal importance. In connection with the Palestrina Society he completed the editing of Palestrina's works in thirty-two volumes, recovering many of the lost compositions and bringing out the whole work in time to celebrate the tercentenary of the composer's death in 1894. He then began to prepare a similar edition of Lassus. His contributions to the *Bausteine zur Musikgeschichte*, the *Cäcilien-Kalendar* (later, *Kirchenmusikalisches Jahrbuch*), and the *Monatshefte für Musikgeschichte* are invaluable to students of musical history. Of

special importance is his thematic catalogue of the Sistine Choir archives in Eitner's *Monatshefte* (1888). He was also a member of the commission for the publication of the *Denkmäler Deutscher Tonkunst*. Among his publications are the *Lieder-Rosenkranz* (1866), a selection of Frescobaldi's organ works (1889), and the *Magister choralis* (1865), which has run through many editions and exists in six languages.

HABERLANDT, GOTTLIEB (1854–), Austrian botanist, born at Ungarisch-Altenburg on Nov. 28, 1854, was director (1910–23) of the plant-physiology department of Berlin university. From 1916 onwards he edited the *Beiträge zur allgemeinen Botanik*. He travelled in the Dutch East Indies to study tropical botany (see his *Eine botanische Tropenreise*, 1893; 3rd ed., 1926). He published many important works on plant physiology; his later work deals more especially with the sensitiveness of plants to external impressions. (See his *Sinnesorgane im Pflanzenreich zur Perception mechanischer Reize*, 1901; 2nd ed., 1906, etc.)

HABERMANN, HUGO FREIHERR VON (1849–), German painter, was born at Dillingen on June 15, 1849. He studied at the Munich academy under Piloty, the leading representative of the realist school in Germany, from 1871 to 1878, and afterwards visited Italy, Paris and Brussels. Since 1905 he has been a professor at the Academy, Munich. While still under the influence of Piloty he painted "The Monk" (1875), "Piloty's studio" (1876) and two portraits of his brother, all of which are in the New State gallery, Munich. His sensibility to colour was extraordinary and he gradually developed a superb technique. "Child of Sorrow" and the portraits of Frau von Torri (1886) and of his mother (1899) are interesting examples of his different phases. Later he became famous for his female nudes—"Frauenakt," "Liegender Modellnakt" (Munich, 1897) and others, which are remarkable for their easy pose and smooth finish. Above all he is a great stylist.

HABINGTON, WILLIAM (1605–1654), English poet, was born at Hendlip Hall, Worcestershire. He was educated at St. Omer. He married about 1632 Lucy, second daughter of Sir William Herbert, first Baron Powys, the lady whom he addressed in lyrical poems entitled *Castara* (1634). In 1635 appeared a second edition enlarged by three prose characters, 14 new lyrics and eight touching elegies on his friend and kinsman, George Talbot. The third edition (1640) contains a third part consisting of a prose character of "A Holy Man" and 22 devotional poems. He also wrote a *Historie of Edward the Fourth* (1640), *The Queene of Arragon* (1640), a tragi-comedy, revived at the restoration; and *Observations upon History* (1641). He died on Nov. 30, 1654.

The Queene of Arragon was reprinted in Dodsley's "Old Plays," vol. ix. (1825); *Castara* was edited by Charles Elton (1812), and by E. Arber with a compact and comprehensive introduction (1870) for his "English Reprints."

HABIT, condition of body or mind, especially one that has become permanent or settled by custom or persistent repetition, hence custom, usage (Lat. *habitus*, from *habere*, to have, hold, or, in a reflective sense, to be in a certain condition). In botany and zoology the term is used both in the above sense of instinctive action of animals and tendencies of plants, and also of the manner of growth or external appearance of a plant or animal. From the use of the word for external appearances comes its use for fashion in dress, and hence as a term for a lady's riding dress and for the particular form of garment adopted by the members of a religious order.

HABITAT, in botany and zoology, the term for the locality in which a particular species of plant or animal thrives.

HABITUAL OFFENDERS. An habitual criminal is one whom the ordinary legal punishments fail to touch, and for whose prevention special measures have to be taken, it being recognized that it is better for the community that seclusion, with proper training, should reduce the chance of further criminal undertakings. By the Prevention of Crime Act, 1908, power was given to the British courts to pass on habitual criminals a sentence of preventive detention in addition to one of penal servitude. The

charge of being an habitual criminal has to be inserted in the indictment on which the offender is to be tried, and this cannot be done without the consent of the director of public prosecutions and after certain notice has been given to the officer of the court trying the prisoner and to the offender himself. A person cannot be found guilty of being an habitual criminal unless the jury finds on evidence that, since attaining the age of 16, he has, at least three times previously to the crime charged in the indictment on which he is being tried, been convicted of a "crime," and that he is leading persistently a dishonest or criminal life; or that he, on previous conviction, has been found an habitual criminal and sentenced to preventive detention. "Crime" means any felony, or uttering or possessing counterfeit coin; or obtaining goods or money by false pretences; or the offence of conspiracy to defraud; or any misdemeanour under s. 28 of the Larceny Act, 1916. There is an appeal to the court of criminal appeal, and the sentence of preventive detention takes effect immediately after the sentence of penal servitude. There is power for the secretary of State to discharge on licence, and the sentence of preventive detention must be reviewed by the secretary of State every three years. That the habitual offender is not quite irredeemable has been demonstrated by the experience of Camp Hill in England, to which men are sent, and of the women's prison at Liverpool. Men released on licence are placed under the charge of the Central Association for the Aid of Discharged Convicts, and women under the charge of the Aylesbury Association. (See RECIDIVISM.) (W. DE B. H.)

United States.—The American practice with respect to the penal treatment of the habitual offender is not easy to summarize in a brief statement. With 49 independent jurisdictions—that of the Federal Government and those of the 48 States—each going its own way, only slightly affected by the example of its sister commonwealths and with tides of feeling swaying the annual or biennial legislative sessions, there is constant change and little uniformity in the resultant penal legislation. The recent recrudescence of banditry and crimes of violence in large cities, together with the general though unwarranted conviction that crime in general is on the increase, has found expression in more drastic penal legislation in many States. This has naturally been directed mainly at the habitual offender who is in the foreground of the picture. The definition of the habitual offender is substantially the same as that of the English act, a convict who has had three previous convictions of felony, but the penalty is far more severe. For a generation the courts of criminal jurisdiction in most of the States have had the power, in their discretion, to commit such an offender to a State prison, the equivalent of penal servitude in England, for life. As the judges have, in fact, rarely exercised this power, several of the States, following the lead of New York, have made such a sentence mandatory. This tendency to curb the judicial discretion has been further manifested in setting a much higher minimum term of imprisonment for second and third offenders. While it is true that preventive detention is an important objective of this legislation, its primary purpose is its assumed deterrent effect. Its excessive severity has already created a powerful public sentiment working for its repeal. (See PENOLOGY; RECIDIVISM.) (G. W. Kt.)

HABSBURG or HAPSBURG, the name of the family from which sprang the dukes and archdukes of Austria after 1282, kings of Hungary and Bohemia after 1526, and emperors of Austria after 1804. They were Roman emperors from 1438–1806, kings of Spain 1516–1700, and held innumerable other dignities.

The name Habsburg was derived from the castle of Habsburg, or Habichtsburg (hawk's castle) on the Aar, near its junction with the Rhine, which was built in 1028 by Werner, bishop of Strassburg, and his brother-in-law, Count Radboto. The founder of the house was probably one Guntram the Rich, who has been identified with much probability with a Count Guntram who was involved in a rebellion under Otto I. Radboto's son Werner (d. 1096) and grandson Otto were called counts of Habsburg. Otto's nephew Werner (d. 1167) was father of Albert (d. 1199), who was count of Zürich and landgrave of Upper Alsace. His son Rudolph acquired Laufenburg and the protectorate over the "Waldstätte"

(Schwyz, Uri, Unterwalden and Lucerne). On his death in 1232, his two sons Albert and Rudolph partitioned his lands. The line of Habsburg-Laufenburg, Rudolph's descendants, became extinct in 1415, having previously sold back Laufenburg and other districts to the senior branch (Habsburg-Habsburg). Albert, founder of this branch, who died in 1239, had married Hedwig of Kyburg (d. 1260). Their son was Rudolph I. (q.v.), elected German king 1273.

Henceforward the history of the family of Habsburg is synonymous with that of their dominions. The present article will confine itself to stating the chief events in the history of the family as such. The attached genealogical tables show the ramifications of the family; its chief members are noticed in separate articles.

The earlier Habsburgs vested the government and enjoyment of their domains, not in individuals but in all male members of the family in common. Thus Rudolph I., as emperor, bestowed Austria and Styria on his two sons Albert and Rudolph, in common. By a family ruling of 1283, Rudolph renounced his share; but the question arose again after Albert's death. Owing partly to the representations of the Estates, a system of condominium was adopted, and the partition again avoided. In 1364 Rudolph made a fresh family compact with his younger brothers, which, while admitting the principle of equal rights, vested the rule and chief position *de facto* in the head of the house; but after his death, the partition was actually effected (agreement of Neuberg, 1379). Albert III. took the duchy of Austria, his brother Leopold III. Styria, Carinthia and the Tyrol, for himself and his descendants. Titles, arms and banner remained common to both lines, fiefs of the empire (Alsace) were held in condominium, and on the extinction of either male line, its dominions were to pass to the other.

This policy of partition was one of the main causes of the decline of Austria in the later Middle Ages. While the Austrian line was perpetuated only by one son in each generation until it became extinct on the death of Ladislaus Postumus in 1457, the domains then passing to the Styrian line, the latter had been again subdivided into an Inner Austrian and a Tyrolean line. The Emperor Frederick III. (q.v.) first acted, in his capacity as senior member of full age of his house, as regent both for Ladislaus Postumus in Austria and for Sigismund in the Tyrol; and as all the collateral lines now died out, his son Maximilian reunited all the Habsburg possessions in his own person.

During the period 1282-1493 the Habsburgs increased their dominions and dignities in many directions. The title of German king, held by Rudolph I., was held again by Albert I. (q.v.) from 1298-1308. Frederick the Fair, who assumed the title 1314-22, was the nominee of a minority of electors, and it then passed from the family until reassumed by Albert II. (q.v.) in 1438. From this date onward the titles of German king and Roman emperor remained in the Habsburg family uninterruptedly, with the single exception of the reign of Charles Albert, elector of Bavaria (1742-45), until their extinction. To the duchies of Austria and Styria, which the sons of Rudolph I. received in 1282, they and their successors were able to add the Tyrol, Vorarlberg, Carinthia, Carniola, and Gorizia. By the *privilegium maius* of 1453, they received a special status in the empire and the title of archduke (q.v.). On the other hand, a long series of reverses deprived them of practically all their possessions in Switzerland (Morgarten 1315, Sempach 1356, "perpetual peace" of 1474), and they were unable to retain the coveted crowns of Bohemia and Hungary. The crown of Bohemia, bestowed by Albert I. on his son Rudolph in 1306, was lost on Rudolph's death in the following year. It was again bequeathed, together with that of Hungary, to Albert II. by his father-in-law Sigismund of Luxemburg in 1437; but Albert died in 1439 and both crowns were lost when his son, Ladislaus Postumus, died unmarried in 1437.

Hitherto the Habsburgs had been identified only with the conduct of their Austrian dominions, which, if increasing in extent, had certainly not added to their prosperity since the days of the Babenbergers; and with the somewhat equivocal title of German king and Roman emperor. Maximilian I. (q.v.) opened up a new era for his house. He restored and consolidated his Austrian

dominions; and by his marriage with the heiress of Charles the Bold of Burgundy, increased them by a second family domain on the other flank of the empire, consisting, as finally delimited, of the Netherlands, Artois, and the Franche Comté. His efforts to secure a foothold in Italy, after his second marriage with Bianca Sforza, daughter of the Duke of Milan, proved unsuccessful; but he more than compensated for many disastrous wars by the brilliance of his marriage policy. His only son, Philip I. (q.v.), married Joanna, daughter of Ferdinand and Isabella of Spain, and died in 1506, leaving two sons, Charles and Ferdinand. Charles succeeded his father in the Netherlands in 1506 and his grandfather in Spain in 1516, becoming the emperor Charles V. (q.v.) on Maximilian's death in 1519. At the same time he succeeded to all the Habsburg dominions; but by the Treaty of Brussels (1522) he assigned to his brother Ferdinand (see FERDINAND I., Roman Emperor) the Austrian dominions. In the same year Ferdinand married Anne, daughter of Wladislaus, king of Hungary and Bohemia; and when his childless brother-in-law, King Louis, was killed at Mohacs (1526), he laid claim to Bohemia and Hungary both by right of his wife and by treaty. In each case the Estates denied the validity of the hereditary title; but those of Bohemia elected Ferdinand king in 1526. In Hungary he was also elected, but a counter-party elected John Zapolya (q.v.), with whom Ferdinand made a treaty in 1538, receiving north-western Hungary and the succession (afterwards repudiated) to Zapolya's dominions.

The Habsburgs had now reached the summit of their power. The prestige which belonged to Charles as head of the Holy Roman empire was backed by the wealth and commerce of the Netherlands and of Spain, and by the riches of the Spanish colonies in America. In Italy he ruled over Sardinia, Naples and Sicily, which had passed to him with Spain, and the duchy of Milan, which he had annexed in 1535; to the Netherlands he had added Friesland, the bishopric of Utrecht, Gröningen and Gelderland, and he still possessed Franche-Comté and the fragments of the Habsburg lands in Alsace and the neighbourhood. Add to this Ferdinand's inheritance, the Austrian archduchies and Tirol, Bohemia with her dependent provinces, and a strip of Hungary, and the two brothers had under their sway a part of Europe the extent of which was great, but the wealth and importance of which were immeasurably greater.

When Charles V. abdicated he was succeeded as emperor, not by his son Philip, but by his brother Ferdinand. Philip became king of Spain, ruling also the Netherlands, Franche-Comté, Naples, Sicily, Milan and Sardinia, and the family was definitely divided into the Spanish and Austrian branches. For Spain and the Spanish Habsburgs the 17th century was a period of loss and decay, the seeds of which were sown during the reign of Philip II. (q.v.). The northern provinces of the Netherlands were lost practically in 1609 and definitely by the treaty of Westphalia in 1648; Roussillon and Artois were annexed to France by the treaty of the Pyrenees in 1659, Franche-Comté and a number of towns in the Spanish Netherlands by the treaty of Nijmegen in 1678. Finally Charles II. (q.v.), the last Habsburg king of Spain, died childless in Nov. 1700, and by the peace of Rastatt (1714) which terminated the War of the Spanish Succession, Spain passed from the Habsburgs to the Bourbons. However, the Austrian branch of the family received the Italian possessions of Charles II., except Sicily, which was given to the duke of Savoy, and also the southern Netherlands, which are thus often referred to as the Austrian Netherlands; and retained the duchy of Mantua, which it had seized in 1708. In 1717 it received Sicily in exchange for Sardinia; but in 1735 had to cede Novara, Tortona and the two Sicilies, receiving in return the duchies of Parma and Piacenza.

In the Austrian line fresh partitions were effected during the 16th and 17th centuries; but after 1665 this disastrous policy was finally abandoned in favour of that of primogeniture throughout the Austrian dominions.

The Thirty Years' War deprived the Habsburgs of Alsace, came near to ruining the empire, and forced the Habsburgs to devote themselves more and more exclusively to their family dominions. After breaking the resistance of the nobles, Ferdinand II. (q.v.)

declared the thrones of Bohemia (1617) and Moravia (1618) hereditary in his dynasty. Half a century later the Turks were driven back out of Hungary. The Diet of Pressburg (1687) recognized the male line of the Habsburgs in primogeniture as hereditary kings of Hungary; the Peace of Karlovitz (1699) gave them *de facto* possession of most of Hungary, including Transylvania, which had already accepted their rule. The Banat was added in 1718.

Leopold I. (q.v.) had made arrangements with his two sons, Joseph and Charles, for a fresh partition of the Spanish and Austrian dominions. The former were, however, lost to the Habsburgs after the War of the Spanish Succession. Joseph I. (q.v.) died without male issue, and Charles VI. (q.v.), who succeeded him as emperor in 1711, was also without sons. In 1713 he issued (as an unilateral expression of his will, communicated to his Privy Council) his wish that all his dominions should form an indivisible whole, and should pass as such to his male descendants in primogeniture, after them to his female descendants, after them to Joseph's daughters, after them to the other branches of his family. This "Pragmatic Sanction," the most famous of the Habsburg dynastic instruments, was that by which their relation within the dynasty and with their subjects were regulated until the fall of the dynasty. The formal acceptance of it was received in various forms by the Estates of all Charles' dominions from 1700 onward; it was publicly promulgated in 1724, and guaranteed by the imperial diet in 1731 and by the main European powers severally. With Charles' death in 1740, the true line of the Habsburgs became extinct; but his daughter, Maria Theresa (q.v.), who in 1736 had married Francis Stephen, duke of Lorraine (see FRANCIS I.) succeeded him, becoming founder of the house of Habsburg-Lorraine. The Pragmatic Sanction was respected within her dominions, but not outside them. Maria Theresa lost most of Silesia to Prussia, but later acquired part of Poland, while in Italy she surrendered Parma and Piacenza to Spain and part of Milan to Sardinia but acquired Tuscany through her husband. Under Joseph II. (q.v.) the Innviertel and the Bukovina were gained, and the Polish frontier revised, but the Netherlands rebelled successfully.

The Habsburgs emerged from the many changes brought about during the Napoleonic era shorn of the Netherlands, but in possession of Galicia and Lodomeria, Salzburg, Dalmatia and the kingdom of Lombardy-Venetia. The title of Holy Roman emperor had been abandoned by Francis II. in 1806, but in 1804 he had assumed the title of emperor of Austria as Francis I. (q.v.). In addition, the family of Habsburg possessed certain lands in Italy which formed no part of the Austrian empire. These were the grand duchy of Tuscany, which passed on the death of the emperor Francis I., by special arrangement, to his younger son Leopold, and after his succession to the empire as Leopold II. (q.v.) to a third brother, Ferdinand, under whose rule and that of his son Leopold it remained until incorporated in the kingdom of Sardinia in 1859; and the duchy of Modena, acquired by the emperor Leopold II.'s younger son Ferdinand by his marriage with Mary Beatrice d'Este, which was also lost in 1859. The Modena-d'Este line of the Habsburgs became extinct with the death of Francis V. (q.v.) in 1875.

Francis I. was succeeded as emperor by his son Ferdinand I. (q.v.), who abdicated after the revolution of 1848 in favour of his young nephew Francis Joseph (q.v.). In the course of his long reign, Francis Joseph lost the Lombard-Venetian kingdom to Italy (1859, 1866), but acquired Bosnia and the Hercegovina (mandate of occupation 1877, annexation 1908). In 1867 his relations with Hungary were reorganised under the Compromise of that year; while in 1915 the title of "Austrian empire" was granted to his remaining dominions. A remarkable but short-lived extension of the Habsburg dominions was formed by the assumption in 1863 of the title of Emperor of Mexico by Francis Joseph's brother Maximilian (q.v.).

Fall of the Habsburgs.—Francis Joseph was succeeded in 1916 by his great-nephew Charles I. (q.v.). At that time his subjects still protested loyalty to the dynasty; but during the collapse of Oct. 1918, consequent on the World War, the Poles,

Ruthenians, Czechoslovaks and Yugoslavs repudiated his authority. On Oct. 27 Count Andrassy, the Austro-Hungarian foreign minister, accepted President Wilson's demands "regarding the rights of the peoples of Austria-Hungary, particularly those of the Czechoslovaks and Yugoslavs." The states of Poland, Yugoslavia and Czechoslovakia soon after came formally into being, and although Charles never renounced his sovereign rights in these territories, the Habsburg family afterwards made no serious claim to reassert them. The treaties of Saint Germain and Trianon perpetuated the boundaries of these States, and confirmed Italy and Rumania in the possession of their parts of the former Habsburg monarchy.

There remained only German-Austria and Hungary. On Nov. 11, 1918, Charles issued a proclamation in which he stated:

Still, as ever, filled with unchanging love towards all my peoples, I will not oppose my person as an obstacle to their free development. I recognise in advance the decision which German-Austria will take on its future form of State. The people has assumed the government through its representatives. I renounce any share in the affairs of State. At the same time I remove my Austrian Government from its office.

The provisional Government of German-Austria proclaimed a republic on the following day. On March 12, 1919, following the elections, the first national assembly repeated this declaration. Charles, however, refused to abdicate in his own name and that of his dynasty. Thereupon the national assembly, by decree of April 2, 1919, banished all Habsburgs from Austria and confiscated the family property for the benefit of the war invalids. Habsburgs who renounced all rights other than those of private citizens were, however, allowed to live unmolested in Austria, and several of them did so. The legitimist movement in Austria has been very weak since these events. Austrian republicans claim that Charles's acceptance in advance of the republic was equivalent to a renunciation of the throne.

Charles issued a similar proclamation to Hungary on Nov. 13 which Karolyi answered by proclaiming the Hungarian republic on Nov. 16. When, however, the Right regained power in Hungary after Karolyi's and Kun's régimes, it proceeded by Act I. of 1920 to abolish all legislation passed by these two Governments. Hungary, therefore, reverted to the status of a kingdom, and controversy arose whether or not Charles's action had annulled the pragmatic sanction.

On Feb. 2, 1920, during the discussions on the draft treaty of Trianon, the Allied and Associated Powers declared that a Habsburg restoration in Hungary would be a matter of international concern and that they would neither recognise nor tolerate such a restoration. They attempted to insist on Hungary's styling herself a republic, but finally, in view of the objections raised by the Hungarian delegation, compromised on the word "Hungary."

Charles returned to Hungary and attempted to assert his claim on March 27 and Oct. 20, 1921 (see HUNGARY). After the second coup, under pressure from the Powers and the Little Entente, the Hungarian Parliament passed a decree (Nov. 3, 1921) whereby the sovereign rights of Charles and the pragmatic sanction were declared forever abrogated and the right of the Hungarian nation to elect its king by free choice restored. On Nov. 10 Hungary addressed a note to the Powers consenting only to elect its king in agreement with the Powers and accepting the notes of Feb. 2 and April 3, 1921. The Legitimist party, however, continued to look on Otto, Charles's eldest son, as the legitimate king after Charles's death on April 1, 1922.

Despite their unique career, the Habsburgs produced no statesman of great ability, with the exception of Charles V., and perhaps of Joseph II. Several members of the family displayed marked traces of insanity, and during the last century of their rule they were proverbial for their scandals and eccentricities. With hardly an exception, they were strongly conservative and intensely convinced upholders of the monarchical tradition. From the 16th century onward, they were nearly all extreme supporters of the Catholic idea; the title of Apostolic Majesty, which they wore as kings of Hungary, represented a very real attitude. The few exceptions—Joseph II., the Crown Prince Rudolph, and "Johann Orth"—all came to mysterious and unhappy ends. The

family tradition was exceedingly strict among them to the last, as was well exemplified when the Archduke Francis Ferdinand (*q.v.*) contracted his morganatic marriage. They owed their position chiefly to outward circumstance and to a series of marriages so adroit and successful as to give rise to the proverb "*Bella gerant alii, tu, felix Austria, nube*" (Let others wage war, do you, happy Austria, marry). As a family they succeeded in amassing great wealth, the fortunes accumulated by the Modena and d'Este branch and their heirs being particularly brilliant. After the fall of their dynasty they lost all valuables and estates owned in virtue of their rank. The income of the senior branch of the family was left very small.

For the origin and early history of the Habsburgs see G. de Roo, *Annales rerum ab Austriacis Habsburgicæ gentis principibus a Rudolpho I. usque ad Carolum V. gestiarum* (Innsbruck, 1592, fol.); M. Herrgott, *Genealogia diplomatica augustæ gentis Habsburgicæ* (Vienna, 1737-1738); E. M. Fürst von Lichnowsky, *Geschichte des Hauses Habsburg* (Vienna, 1836-1844); A. Schulte, *Geschichte der Habsburger in den ersten drei Jahrhunderten* (Innsbruck, 1887); T. von Liebenau, *Die Anfänge des Hauses Habsburg* (Vienna, 1883); W. Merz, *Die Habsburg* (Aarau, 1896); W. Gisi, *Der Ursprung der Häuser Zähringen und Habsburg* (1888); and F. Wehrich, *Stammtafel zur Geschichte des Hauses Habsburg* (Vienna, 1893). For the history of the Habsburg monarchy see Langl, *Die Habsburg und die denkwürdigen Stätten ihrer Umgebung* (Vienna, 1895); and E. A. Freeman, *Historical Geography of Europe* (1881). (C. A. M.)

HACHETTE, JEANNE, French heroine. Jeanne Lainé, or Fourquet, called Jeanne Hachette, was born about 1454, and is known solely for an act of heroism which on June 27, 1472, saved Beauvais when it was on the point of being taken by the troops of Charles the Bold, duke of Burgundy. The town was defended by only 300 men-at-arms, commanded by Louis de Balagny. A Burgundian man-at-arms had actually planted a flag upon the battlements, when Jeanne, axe in hand, flung herself upon him, hurled him into the moat, tore down the flag, and revived the drooping courage of the garrison. Louis XI. instituted a procession in Beauvais called the Procession of the Assault, and married Jeanne to her chosen lover Colin Pilon, loading them with favours.

See Georges Vallat, *Jeanne Hachette* (Abbeville, 1898).

HACHETTE, LOUIS CHRISTOPHE FRANÇOIS (1800-1864), French publisher, was born at Bethel in the Ardennes on May 5, 1800. In 1826 he established in Paris a publishing business for the issue of works adapted to improve the system of school instruction, or to promote the general culture of the community. He published manuals in various departments of knowledge; dictionaries of modern and ancient languages, educational journals, and French, Latin and Greek classics annotated with great care by the most eminent authorities. After 1850, in conjunction with other partners, he published a cheap railway library, scientific and miscellaneous libraries, an illustrated library for the young, libraries of ancient literature, of modern foreign literature, and of modern foreign romance, a series of guide-books and a series of dictionaries of universal reference. In 1855 he also founded the popular weekly, *Le Journal pour tous*. Hachette died on July 31, 1864.

HACHURE, the term (French for "hatching") for the conventional lines used in hill or mountain shading upon a map (*q.v.*) to indicate the slope of the surface, the depth of shading being greatest where the slope is steepest. The method is less accurate than that of contour lines, but gives an indication of the trend and extent of a range or mountain system, especially upon small-scale maps.

HACIENDA, a Spanish term for a landed estate. It is commonly applied in Spanish America to a country estate, on which stock-raising, manufacturing or mining may be carried on, usually with a dwelling-house for the owner's residence upon it. It is thus used loosely for the country house or farm, or for the mining works or offices so situated.

HACKBERRY, a name given to the fruit of *Celtis occidentalis*, belonging to the family Ulmaceæ, to which also belongs the elm (*Ulmus*). It is also known under the name of "sugar-berry," "beaver-wood" and "nettle-tree." The hackberry tree is of middle size, attaining from 60 to 80 ft. in height (though sometimes

reaching 130 ft.), and with the aspect of an elm. The leaves are ovate in shape, with a very long taper point, rounded and usually very oblique at the base, usually glabrous above and soft-pubescent beneath. The soft filmy flowers appear early in the spring before the expansion of the leaves. The fruit is oblong, about half to three-quarters of an inch long, of a reddish or yellowish colour when young, turning to a dark purple in autumn. This tree is found in North America in deep shady forests bordering river banks from Canada (where it is very rare) to the southern states. The fruit has a sweetish and slightly astringent taste, and is largely eaten in the United States. The seeds contain an oil like that of almonds. The bark is tough and fibrous like hemp, and the wood is heavy, soft, fragile and coarse-grained, and is used for making fences and furniture. The root has been used as a dye for linens.

HACKENSACK, a town of New Jersey, U.S.A., on the Hackensack river, 13 m. N. of Jersey City, served by the Erie Railroad company; the county seat of Bergen county. The population was 17,667 in 1920 (20% foreign-born white, nearly half from Italy) and was estimated locally at 26,500 in 1928. The town rises gradually from the bank of the river to a ridge commanding good views to the south and east. It is principally a suburban residential community, but it has various manufacturing industries (including paper and silk mills, iron works, wall-paper and jewelry factories) with an output in 1925 valued at \$5,157,467. Hackensack was settled by the Dutch about 1640, and was named after the Hackensack Indians of the region, whose chief Oritany was a friend of the whites.

HACKER, ARTHUR (1858-1919), English painter, was born in London on Sept. 25, 1858, the son of Edward Hacker, a line engraver. He became a student at the Royal Academy schools in 1876, and from 1880-81 worked at the *atelier* Bonnat, Paris, subsequently travelling widely both in Europe and in North Africa. The best known of his paintings are "Her Daughter's Legacy," "The Mother" and "The Cloud"; his "Annunciation" (1892) was bought by the Chantrey trustees. He became A.R.A. in 1894 and R.A. in 1910. Hacker also became well known as a portrait painter. He died in London on Nov. 12, 1919.

HACKETT, JAMES HENRY (1800-71), American actor, was born in New York. In 1826 he went on the stage, where he soon established a reputation as a player of eccentric character parts. As Falstaff he was no less successful in England than in America. At various times he went into management, and he was the author of *Notes and Comments on Shakespeare* (1863).

His son, JAMES KETELTAS HACKETT (1869-1926), born at Wolfe Island, Ont., also became an actor and had considerable success in romantic and Shakesperian parts. He died in Paris on Nov. 8, 1926.

HACKLÄNDER, FRIEDRICH WILHELM VON (1816-1877), German novelist and dramatist, was born at Burt-scheid near Aix-la-Chapelle on Nov. 1, 1816. A short period of service in the Prussian army resulted in his *Bilder aus dem Soldatenleben im Frieden* (1841). After a journey to the east, he was appointed secretary to the crown prince of Württemberg. In 1857 he founded, in conjunction with Edmund von Zoller, the illustrated weekly, *Über Land und Meer*. In 1859 Hackländer was appointed director of royal parks and public gardens at Stuttgart; he died on July 6, 1877.

Hackländer was a voluminous writer; the most complete edition of his works is the third, published at Stuttgart in 1876, in 60 volumes. There is a good selection in 20 volumes (1881). See *Roman meines Lebens* (2 vols., 1878), and H. Morning, *Erinnerungen an F. W. Hackländer* (1878).

HACKNEY, a north-eastern metropolitan borough of London, England, bounded W. by Stoke Newington and Islington, and S. by Shoreditch, Bethnal Green and Poplar, and extending N. and E. to the boundary of the county of London. Pop. (1921), 222,142. In the 13th century the name appears as Hackenaye or Hacquenye, but the derivation is doubtful. Roman and other remains have been found in Hackney marshes. The bishop of London was lord of the manor from 1290 to 1550, when it was granted to Thomas, Lord Wentworth. In 1697 it came into the hands of the

Tyssen family. Extensive property in the parish also belonged to the priory of the Knights Hospitallers of St. John of Jerusalem at Clerkenwell. From the 16th to the early 19th century there were many fine residences in Hackney. The neighbourhood had at one time an evil reputation as the haunt of highwaymen. It is a poor and populous district. The borough includes the districts of Clapton in the north, Homerton in the east, and Dalston and part of Kingsland in the west. On the east lies the valley of the Lea, which flows in several branches, and is bordered, immediately outside the borough, by the reservoirs of the East London water-works. In these low lands lie the Hackney Marshes (338 acres), and the borough also contains part of Victoria park and the Hackney Commons. The only historic building is the tower of the ancient parish church of St. Augustine, with the chapel of the Rowe family. The parliamentary borough of Hackney comprises north, central and south divisions, each returning one member.

HACKNEY, originally a riding-horse (from Fr. *haquenée*, an ambling horse or mare, especially for ladies to ride; the English "hack" is simply an abbreviation). Now, however, the hackney is bred for driving as well as riding (see HORSE: *Breeds*). From the hiring-out of hackneys, the word came to be associated with employment for hire (so "a hack," or "drudge"), e.g., hackney-chair, hackney-boat. The hackney-coach, a coach with four wheels and two horses, was a hired public conveyance (see CARRIAGE).

HADAD, the name of a Syrian deity, is met with in the Old Testament as the name of several human persons; it also occurs in compound forms like Benhadad and Hadadezer. The divinity primarily denoted by it is the storm-god who was known as Addu Ramman. The word Hadadrimmon (Zechariah xii. 11) has been a subject of much discussion. According to the older interpreters, the mourning for something that occurred at a place called Hadadrimmon (Maximianopolis) in the valley of Megiddo is meant, the event alluded to being generally held to be the death of Josiah. More recently it has been thought that Hadadrimmon is another name for Adonis (q.v.) or Tammuz, the allusion being to the mournings by which the Adonis festivals were usually accompanied.

HADDINGTON, EARL OF, a Scottish title bestowed in 1627 upon Thomas Hamilton, earl of Melrose (1563-1637). Thomas was a lawyer who became a lord of session as Lord Drumcarn in 1592. He was on very friendly terms with James VI., and was one of the eight men, called the Octavians, who were appointed to manage the finances of Scotland in 1596. Hamilton became secretary of State for Scotland (1612), and received a barony in 1613. In 1616 he became lord president of the court of session, and in 1619 was created earl of Melrose, a title exchanged in 1627 for that of earl of Haddington. After the death of James I. the earl resigned his offices, but served Charles I. as lord privy seal. He died on May 29, 1637. James referred familiarly to his friend as *Tam o' the Cowgate*, his Edinburgh residence being in this street.

The earl's eldest son THOMAS, the 2nd earl (1600-1640), was a covenanter and a soldier. His sons, THOMAS (d. 1645) and JOHN (d. 1669), became respectively the 3rd and 4th earls of Haddington, and John's grandson THOMAS (1679-1735) succeeded his father CHARLES (c. 1650-1685) as 6th earl in 1685, although he was not the eldest but the second son. Charles had married Margaret (d. 1700), the heiress of the earldom of Rothes. It was agreed that the two earldoms should be left separate; thus the eldest son John became earl of Rothes while Thomas became earl of Haddington. Thomas died on Nov. 28, 1735.

THOMAS (1780-1858), 9th earl, was made a peer of the United Kingdom as Baron Melros of Tynninghame, a title which became extinct upon his death. He was lord-lieutenant of Ireland (1834-35) under Sir Robert Peel, and in Peel's second administration (1841-1846) was first lord of the admiralty and then lord privy seal. At his death (Dec. 1, 1858) the earldom passed to his kinsman, GEORGE BAILLIE (1802-1870), a descendant of the 6th earl. This nobleman took the name of Baillie-Hamilton, and his son GEORGE (1827-1917) became 11th earl of Haddington in 1870. In 1917 he was succeeded by his grandson.

See *State Papers of Thomas, Earl of Melrose*, published by the Abbotsford Club in 1837, and Sir W. Fraser, *Memorials of the Earls of Haddington* (1889).

HADDINGTON, royal, municipal and police burgh, parish and county town, East Lothian, Scotland. Pop. (1921) 4,053. It is situated on the Tyne, 18 m. E. of Edinburgh by the L.N.E.R. On the right bank of the river lies the old suburb of Nungate, interesting as having contained the Giffordgate, where John Knox was born, and where also are the ruins of the pre-Reformation chapel of St. Martin. St. Mary's church is a 13th century cruciform Decorated building in red sandstone. The nave, restored in 1892, is used as the parish church, but the choir and transepts are roofless, though otherwise kept in repair. In a vault is a fine monument in alabaster, consisting of the recumbent figures of John, Lord Maitland of Thirlestane (1545-1595), chancellor of Scotland, and his wife, with a laudatory sonnet by James VI. In the same vault John, duke of Lauderdale (1616-82), is buried. In the choir is the tombstone which Carlyle erected over the grave of his wife, Jane Baillie Welsh (1801-1866), a native of the town. Before the county buildings, in Tudor style, stands a monument to George, 8th marquess of Tweeddale (1787-1876), who once drove the mail from London to Haddington without taking rest. The corn exchange, next to that of Edinburgh, is the largest in Scotland. The Knox Memorial Institute was erected in 1879 to replace the old and famous grammar school, where John Knox, William Dunbar, John Major and possibly George Buchanan and Sir David Lindsay were educated. In Hardgate Street is "Bothwell Castle," the town house of the earl of Bothwell, where Mary Queen of Scots rested on her way to Dunbar. The leading industries are the manufactures of woollens, brewing, corn milling, iron founding and coach-building.

The burgh is the retail centre for a large district, and its grain markets, once the largest in Scotland, are still of considerable importance. Haddington was created a royal burgh by David I. It also received charters from Robert Bruce, Robert II. and James VI. In 1139 it was given as a dowry to Ada, daughter of William de Warenne, earl of Surrey, on her marriage to Prince Henry, only son of David I. Alexander II. was born there in 1198. Lying in the direct road of the English invaders, the town was burned by King John in 1216 and by Henry III. in 1244. Fortified in 1548 by Lord Grey of Wilton, the English commander, it was besieged next year by the Scots and French, who forced the garrison to withdraw.

HADDOCK (*Gadus aeglefinus*), a fish distinguished from its relative, the cod, by the smaller mouth and the blackish lateral line. From Iceland it ranges southward on both sides of the Atlantic; in the North sea it constitutes nearly half the total weight of fish taken in the trawl. It feeds mainly on molluscs and crustaceans. It grows to a length of 3 ft. but specimens of this size are exceptional.

HADDONFIELD, a borough of Camden county, New Jersey, 6 m. S.E. of Camden, on the Pennsylvania railroad. The population was 5,646 in 1920 (87% native white) and was estimated locally at 11,500 in 1928. It is a residential suburb, with several manufacturing industries, including potteries and a factory making nautical instruments. The borough was settled in 1713, by Elizabeth Haddon, and incorporated in 1875.

HADEN, SIR FRANCIS SEYMOUR (1818-1910), English surgeon and etcher, was born in London on Sept. 16, 1818, the son of Dr. Charles Haden, and was himself a surgeon by profession. Aided by Sir W. R. Drake, he founded the Royal Society of Painter-Etchers and Engravers, and was its president until 1880. In 1843-44, with his friends Duval, Le Cannes and Col. Guibout, he had travelled in Italy and made his first sketches from nature. He studied the works of the great original engravers, Dürer, Lucas van Leyden and Rembrandt. These studies, besides influencing his original work, led to his important monograph on the etched work of Rembrandt. By lecture and book, and with the aid of the memorable exhibition at the Burlington Fine Arts Club in 1877, he endeavoured to give a just idea of Rembrandt's work, which he clearly expressed in his monograph, *The Etched Work of Rembrandt critically reconsidered*, privately printed in 1877,

and in *The Etched Work of Rembrandt True and False* (1895).

Haden's own plates are remarkable for a fine original treatment of landscape subjects; they are free and open in line, clear and well divided in mass, and express a noble and dignified style of his own. Even when working from a picture Haden's personality dominates the plate, as for example in the large plate he etched after J. M. W. Turner's "Calais Pier," which is a classical example of what interpretative work can do in black and white. Of his original plates, more than 250 in number, one of the most notable was the large "Breaking up of the Agamemnon." An early plate, rare and most beautiful, is "Thames Fisherman." "Sub Tegmine" was etched in Greenwich park in 1859; and "Early Morning—Richmond," full of the poetry and freshness of the hour, was done, the artist has said, actually at sunrise. One of the rarest and most beautiful of his plates is "A By-Road in Tipperary"; "Combe Bottom" is another; and "Shere Mill Pond" (both the small study and the larger plate), "Sunset in Ireland," "Penton Hook," "Grim Spain" and "Evening Fishing, Longparish" are also notable examples of his genius. A catalogue of his works was begun by Sir William Drake and completed by N. Harrington (1880). During later years Haden began to practise the sister art of mezzotint engraving, with a measure of the success that he had already achieved in pure etching and in dry point. He was knighted in 1894, and died on June 1, 1910.

Other books by Haden not already mentioned are: *Études à l'eau forte* (1865); *About Etching* (1878-79); *The Art of the Painter-Etcher* (1890).

HADENDOA: see BEJA.

HADERSLEV, a town of Denmark in the province of North-Slesvig. Pop. (1925) 14,326. It lies in a valley on the Hadersleben fjord, which is about 9 m. in length, and communicates with the Little Belt, and is also an important railway junction. The beautiful church of St. Mary dates from the 13th century. The industries are iron-founding, tanning, and the manufacture of tobacco and gloves. The harbour is only accessible to small vessels.

Haderslev is first mentioned in 1228, and received municipal rights from Duke Waldemar II. in 1292. It suffered considerably during the wars between Slesvig and Holstein in the 15th century. In Nov. 1864 it passed with Slesvig to Prussia, returning to Denmark with North-Slesvig by the plebiscite held in 1920 under the terms of the Treaty of Versailles.

HADFIELD, SIR ROBERT ABBOTT (1859-), British metallurgist, was born in Sheffield Nov. 29, 1859. Educated at Sheffield Collegiate school, at an early age he interested himself in metallurgy, subsequently becoming chairman of Hadfields, Ltd., Hecla and East Hecla Works, Sheffield, and director of other important companies. In 1883 he patented his process for the production of manganese steel (see IRON AND STEEL) and became famous as the inventor and improver of various metallurgical processes, including low hysteresis steel and many other special ferrous alloys. He became a member of many scientific committees, and was president of the Iron and Steel Institute (1905-07), of the Faraday Society (1914-20), and of the Society of British Gas Industries (1917-18), besides being master cutler of Sheffield 1899-1900. In 1908 he was knighted, the following year became F.R.S., and was created a baronet in 1917. Sir Robert received many honours from scientific and learned societies. He published over 160 scientific and technical papers of considerable importance. His book *Metallurgy and Its Influence on Modern Progress: with a survey of Education and Research* (1925) is a standard work of reference.

HADFIELDS, LIMITED originated in Hadfields' Steel Foundry Company, founded by the late Mr. Robert Hadfield in 1872. This private concern was registered in 1888 as Hadfields' Steel Foundry Company, Ltd. In 1913 its title was changed to Hadfields', Ltd., and the share capital was raised to £2,500,000 in March 1920.

Before the World War the company employed some 5,000 to 6,000 workpeople, during the war about 15,000, and after the war from 4,000 to 6,000. The Sheffield works occupy an area of 219ac., and their equipment includes 21½m. of railways, 300 cranes, 1,200 machine tools, 40 presses ranging up to 2,000 tons

capacity, electrically driven rolling mills (one of 11,600 max. h.p.) for dealing with alloy steels, including manganese and other special steels; also open-hearth, electric and other furnaces capable of producing about 150,000 tons of steel per annum. The floor area of the works is 51 acres. Hadfields introduced the 51-hour week in 1891; in 1894 there was a further reduction to 48 hours per week. In both instances, the reduction of hours was effected without any decrease of wages. Other welfare work includes the provision of canteens, the support of ambulance work, the equipment of a sports ground, and the encouragement of social functions amongst the workpeople. (L. C. M.)

HADHRAMAUT, a province on the south coast of Arabia, bounded west by Yaman, east by Oman and north by the Great South desert. Its actual limits are vague, but are generally understood to include the Mahra and Qara country between 51° and 56° E., where the desert and the coastal range come close down to the sea.

The main body of the province lies west of 51° E., where its main feature, a long and exceedingly fertile Wadi, known by different names in its various sections, but conveniently styled Wādī Hadhramaut as a whole, runs into the sea. This Wadi rises in the highlands of south-west Arabia about 45° E., and extends eastward for 400 m. in a gentle curve, receiving numerous affluents from the northern slopes of a mountain range which extends eastward from the Yaman and attains in parts, a height of 8,000 feet. Between this range and the sea is a coastal plain of varying width, scored by the channels of Wadis rising on its southern slopes. The principal ports are Makalla and Shihr, which are the centres of a considerable trade carried on between the interior and India, Java, etc. There are also a number of fishing villages along this coast, while the valleys of the coastal plain support some fertile oases irrigated by springs and seasonal torrents.

The southern escarpment of the main range is steeper than the northern slope, which forms a plateau descending to the main Wādī beyond it. The most westerly settlement in the latter is Shabwa, a former capital, now almost buried by the advancing sand. Further east lies a group of important oasis-settlements, of which the chief are Shibam, Saiyun and Tarim in the main Wadi; and Hauta near its junction with Wadi Duwan. Besides these there are numerous settlements, both in the main Wadi and its affluents, with prosperous palm-groves and other cultivation, which practically ceases below Qasm, the most easterly settlement of any importance. At some distance east of Qasm stands the shrine of Nabi Hud, a pre-Islamic saint, whose grave is an important centre of pilgrimage. A similar shrine is that of Nabi Salih in Wadi Sirr, near Shibam. Except after rain, there is no running water in the Hadhramaut valleys, but springs and wells are numerous, and the principal crops are dates, wheat, millet, indigo and tobacco of excellent quality known as Hummi, which is widely exported.

The Mahra country, mainly desert, is ruled by a sultan residing at the coastal village of Kishin and, until 1886, owning the island of Socotra, now under British protection. The mountains of this tract, and of the adjacent Qara district, come close down to the coast, and rise in parts to 4,000 feet. They are, in places, covered with gum-bearing forests producing myrrh and frankincense. This tract was visited and surveyed by the Bents in 1894, who found Sabaeen ruins near Dhafar, and a remarkable harbour at Khor Raury, possibly the Moscha of antiquity.

The name of Hadhramaut is of great antiquity, and occurs in Genesis as Hazarmaveth and Hadoram, sons of Joktan. Greek accounts of the incense country contain mention of Adramytta and Chadramotites. The province certainly enjoyed great prosperity and a highly advanced civilization in ancient times, as evidenced by numerous ruins found in Wadi Duwan and 'Adim. Its people are, in the main, of Qahtan or south Arabian stock, though the population contains a large element of Saiyids (descendants of the Prophet through his grandson, Husain) and other immigrants of northern stock, as well as a considerable mixture of African (originally and to some extent still, slave) blood.

The total population of the tract may be about 150,000, or

rather more if all the Badawin are included. The Saiyids, organized in families, each under a Munsib, are regarded as the religious leaders, and constitute a sort of aristocracy, owning much land but cultivating it through slaves or hired labourers. The tribesmen, partly nomad and partly settled, are divided into two main sections—the Qaaiti being by far the larger, and the Kathiri. The latter, formerly the more powerful, occupy Saiyun, Tarim and their dependent settlements. The Qaaiti, a branch of the Yafa tribe in south-west Arabia, originally came in at the invitation of the Saiyids to protect them from marauding tribes, but have become the virtual rulers of the whole country, with their capital at Makalla. The chiefs of this tribe have long enjoyed a special hereditary status as jamadar or commander-in-chief of an Arab levy maintained by the Indian State of Hyderabad. Many of these tribesmen seek service in this levy, while the Kathiris, since the beginning of the 19th century, have emigrated on a large scale to Java and Sumatra. A large share of the trade of Makalla and Shihir is in the hands of Parsees and other Indians.

Until the World War our knowledge of the province was mainly derived from the Bents and Leo Hirsch (who reached Tarim in 1893), but in 1919 much fresh information was collected by Captain W. H. Lee-Warner, who entered the country on a mission to the Kathiri sultans on behalf of the British Government. At Ghail Ba Wazir he found the chief centre of the Hummi tobacco cultivation and, following up Wadi Himam, he broke new ground. From Quwaira he followed the whole length of the Wadi Duwan and, visiting Shibam, had an interview with the Kathiri leaders at Hazm, beyond it. Unable to proceed further, he retraced his steps by the same route.

At this time the Dutch Government was considering the prohibition of further Arab immigration into Java, owing to seditious activities on the part of the Kathiri elements already there, and there is little doubt that the inland settlements of the province had been profitably engaged during the war in smuggling supplies to the Turks in Yaman. The Qaaiti sultan, Yhalib Ibn Awadh Ibn Umar, who died in 1924, was a staunch supporter of Great Britain, and a man of progressive tendencies. An endemic feud between him and the Kathiri sultan had been patched up by a treaty in 1918, but Lee-Warner was impressed by the conviction that progress in the Hadhramaut could only be assured by the elimination of the Kathiri sultans, whose tyranny and rapacity were the subject of much local complaint, while their intrigues made for unrest in the Qaaiti territory. In both sections of the province the executive administration is in the hands of hereditary Wazirs, who are thus the virtual, though not the nominal rulers.

The revenue of the Qaaiti sultan amounted, in 1919, to 340,000 dollars (Maria Theresa), of which 105,000 dollars accrued from the farming of the tobacco-purchase monopoly. In 1919-20 further light was thrown on the Hadhramaut by O. H. Little (*The Geography and Geology of Makalla*, Cairo, 1925), who made a geological reconnaissance of great value of the coastal plain and southern slopes of the mountain range between Ghail Ba Wazir and Wadi Hajr, south of 14° 45' N. He does not appear to have penetrated into or beyond the mountain range, but within the limits of his survey we have as complete a picture of an important district as any that has ever been made in any part of Arabia.

The xenophobia of the Hadhramaut people has always jealously guarded the country from the intrusion of European explorers, but the few who have penetrated into its recesses have enabled us to form a fairly complete idea of the whole, though the Hadhramaut still provides an immense field for future enterprise.

(H. St. J. B. P.)

HADING, JANE (1859-), French actress, whose real name was Jeanne Alfrédine Tréfourret, was born on Nov. 25, 1859, at Marseilles, where her father was an actor at the Gymnase. She was trained at the local Conservatoire and was engaged in 1873 for the theatre at Algiers, and afterwards for the Khedivial theatre at Cairo, where she played, in turn, coquette, soubrette and *ingénue* parts. When she returned to Marseilles she sang in operetta, besides acting in *Ruy Blas*. Her Paris début was in *La Chaste Suzanne* at the Palais Royal, and she was again heard in operetta at the Renaissance. In 1883 she had a great

success at the Gymnase in *Le Maître de forges*. In 1884 she married Victor Koning (1842-94), the manager of that theatre, but divorced him in 1887. In 1888 she toured America with Coquelin. Her later répertoire included *Le Demi-monde*, Capus's *La Châtelaine*, Maurice Donnay's *Retour de Jérusalem*, *La Princesse Georges* by Dumas fils, and Émile Bergerat's *Plus que reine*.

HADITH. The name given to a compilation of the teachings and life of the prophet Mohammed, which with the Koran forms the supreme authority on matters connected with the Mohammedan religion and legislation. This enormous literature of traditions, which was primarily meant for personal guidance and edification, has coloured the whole method and fabric of Moslem thought. (See ISLAM and MOHAMMEDAN LAW.)

HADLEIGH, a market town in Suffolk, England; 70 m. N.E. from London, the terminus of a branch of the L.N.E. railway. Pop. of urban district (1921) 3,038. Hadleigh, called by the Saxons Heapde-leag, appears in Domesday Book as Hetlega. About 885 Aethelflaed, with the consent of Aethelred, her husband, gave Hadleigh to Christ Church, Canterbury. The dean and chapter of Canterbury have held it since the Dissolution. In the 17th century Hadleigh was famous for the manufacture of cloth, and was incorporated in 1618. It was constituted a free borough under the title of the mayor, aldermen and burgesses of Hadleigh. In 1635, in a list of the corporate towns of Suffolk to be assessed for ship money, Hadleigh is named as third in importance. It declined after the plague in 1636 and in 1687 was deprived of its charter. An unsuccessful attempt to recover it was made in 1701. There is evidence of the existence of a market here as early as the 13th century. James I., granted fairs on Monday and Tuesday in Whitsun week, and confirmed an ancient fair at Michaelmas and a market on Monday. It lies on the Brett, a tributary of the Stour. The church of St. Mary is Perpendicular, with an Early English tower and Decorated spire. The Rectory Tower, a turreted gate-house of brick, dates from 1495. The guild-hall is a Tudor building. Matting and malting are important trades. Hadleigh was one of the towns in which the woollen industry was started by Flemings and survived until the 18th century.

HADLEY, ARTHUR TWINING (1856-1930), American political economist and educator, president of Yale university, was born in New Haven (Conn.), on April 23, 1856, the son of James Hadley, the philologist. He graduated at Yale in 1876 as valedictorian, having taken prizes in English, classics, and astronomy; he studied history and political science at Yale and in Berlin; was a tutor at Yale in 1879-83, instructor in political science in 1883-86, professor of political science in 1886-91, professor of political economy in 1891-99, and dean of the Graduate school in 1892-95; and in 1899 became president of Yale university—the first layman to hold that office.

He retired as president emeritus in 1921 but continued to act as director of various railroads. He was commissioner of the Connecticut bureau of labour statistics in 1885-87. As an economist he first became widely known through his investigation of the railway question and his study of railway rates, which antedated the popular excitement as to rebates. His *Railroad Transportation, its History and Laws* (1885) became a standard work, and appeared in Russian (1886) and French (1887); he testified as an expert on transportation before the Senate committee which drew up the interstate commerce law; and wrote on railways and transportation for the Ninth and Tenth Editions (of which he was one of the editors) of the *Encyclopædia Britannica*, for Lator's *Cyclopaedia of Political Science, Political Economy, and Political History of the United States* (3 vol., 1881-84), for *The American Railway* (1888), and for *The Railroad Gazette*, of which he was associate editor in 1887-89, and other periodicals. His idea of the broad scope of economic science, especially of the place of ethics in relation to political economy and business, is expressed in his writings and public addresses. In 1907-08 he was Theodore Roosevelt professor of American History in the University of Berlin. He also lectured in England. He died at Kobe, Japan, on March 6, 1930. Among his publications

are: *Economics: an Account of the Relations between Private Property and Public Welfare* (1896); *The Education of the American Citizen* (1901); *The Relations between Freedom and Responsibility in the Evolution of Democratic Government* (1903); *Undercurrents in American Politics* (1915); *Economic Problems of Democracy* (1923); and *The Conflict between Liberty and Equality* (1925).

HADLEY, HENRY KIMBALL (1871—), American composer, was born in Somerville (Mass.), on Dec. 20, 1871. He studied in Boston and Vienna. In 1904 he went to Germany, where he was Kapellmeister at the Mainz Opera House for two seasons, and in 1909 produced his opera *Safe*. Hadley toured Europe in 1908 as a guest conductor, presenting his tone poem *Salome*, after Oscar Wilde's tragedy. He was conductor of the Seattle Symphony Orchestra (1909–11) and of the San Francisco Symphony Orchestra (1911–15) and became associate conductor of the N.Y. Philharmonic Orchestra in 1921. He has composed four other grand operas: *A Night in Old Paris*, *Azora* (Chicago Opera Company), *Bianca* (Society of American Singers), and *Cleopatra's Night* (Metropolitan Opera House); ode music for the Worcester (Mass.) Festival (60th anniversary) and *Resurgam* for the Cincinnati Festival, 1923, in addition to four symphonies, overtures and cantatas, five tone poems, ballet suites and more than 150 songs. In 1923 he conducted his *Resurgam* in London, and his tone poem *The Ocean* in Stockholm and Amsterdam, while in 1927 he went by invitation to South America, when he directed performances of his own symphonic works at Buenos Aires.

HADLEY, JAMES (1821–1872), American scholar, was born March 30, 1821, in Fairfield (N.Y.). He graduated from Yale in 1842, studied in the theological department of Yale, and in 1844–45 was a tutor in Middlebury college. Then at Yale he was tutor, assistant professor, and professor of Greek, from 1851 until his death in New Haven, Nov. 14, 1872. Although he knew many ancient and modern languages, he published little. He was also an able mathematician.

His most original written work was an essay on Greek accent, published in a German version in Curtius's *Studien zur griechischen und lateinischen Grammatik*. Hadley's *Greek Grammar* (1860; revised by Frederic de Forest Allen, 1884) long held its place in American schools. In 1873 were published his *Introduction to Roman law* (ed. by T. D. Woolsey) and his *Essays, Philological and Critical* (ed. by W. D. Whitney).

See the memorial by Noah Porter in *The New Englander*, vol. xxxii, p. 35–55 (Jan. 1873); and the sketch by his son, A. T. Hadley, in *Biographical Memoirs of the National Academy of Sciences*, vol. v. (1905), p. 247–254.

HADOW, SIR WILLIAM HENRY (1859—), British scholar and musician, was born at Ebrington, Glos., Dec. 27, 1859. He was educated at Malvern and Worcester College, Oxford, and after taking his degree remained at Oxford as a tutor and fellow of his college. In 1909 he became principal of Armstrong College, Newcastle, retaining this post until 1919, when he became vice-chancellor of Sheffield University. He was in 1918 appointed assistant director of education for the troops by the War Office and also worked for the Y.M.C.A. He was knighted in 1918 and was made a C.B.E. in 1920. In 1922 he became Stevenson Lecturer to the University of Glasgow and in 1927 he presided over a committee which investigated the possibilities of adult education by means of broadcasting.

Sir Henry Hadow first took up the study of music at Darmstadt in 1882. When his *Studies in Modern Music* appeared (vol. i. Berlioz, Schumann, Wagner, 1894; vol. ii. Chopin, Dvořák, Brahms, 1895), they were received with enthusiasm as representing a layman's wider outlook on, and keen insight into, subjects usually left to professional writers on music. In *A Croatian Composer* (1897) he contributed a valuable theory on the Slavonic origin of Haydn's melodic material. He also wrote *Sonata Form* (1896); the volume "The Viennese Period" (1904) in *The Oxford History of Music*, of which he was the editor; *Citizenship* (1923); and *Music* (1924) in the Home University Library. His compositions include songs, piano pieces and incidental music to Robert Bridge's *Demeter* (1905).

HADRIA [mod. *Atri* (q.v.)], an ancient town of Picenum, belonging to the Praetuttii. It became a colony of Rome in 290 B.C. and remained faithful to Rome. The family of Hadrian came from here. The crypt of the cathedral of the modern town was originally a large Roman cistern; another forms the foundation of the ducal palace; and in the eastern portion of the town there is a complicated system of underground passages for collecting and storing water.

HADRIAN (PUBLIUS AELIUS HADRIANUS), Roman emperor A.D. 117–138, was born on Jan. 24, A.D. 76, at Italica in Hispania Baetica, where his ancestors, originally from Hadria in Picenum, had been settled since the time of the Scipios. On his father's death in 85 or 86 he was placed under the guardianship of two fellow-countrymen, his kinsman Ulpian Trajanus (afterwards the emperor Trajan), and Caelius Attianus (afterwards prefect of the praetorian guard). He spent the next five years at Rome, but at the age of fifteen he returned to his native place and entered upon a military career. Trajan sent for him to Rome in 93, and after filling the usual minor civil posts he started serious military service as tribune to the IInd legion, stationed at Buda-Pesth (95). He spent four years on that frontier, being sent to Trajan with the army's congratulations in 97, and returned to Rome with Trajan in 99. In 100 the Empress Plotina arranged a marriage between him and Vibia Sabina, Trajan's great-niece. In 101 Hadrian was quaestor, in 105 tribune of the people, in 106 praetor. He served with distinction in both Dacian campaigns; in the second Trajan presented him with a valuable ring which he himself had received from Nerva, a token of regard which seemed to designate Hadrian as his successor. In 107 Hadrian was *legatus praetorius* of lower Pannonia, in 108 *consul suffectus*, *legatus* in the Parthian campaign (113–117), in 117 *consul designatus* for the following year, in 119 consul for the third and last time only for four months. When Trajan, owing to a severe illness, decided to return home from the East, he left Hadrian in command of the army and governor of Syria. On Aug. 9, 117, Hadrian, at Antioch, was informed of his adoption by Trajan, and, on the 11th, of the death of the latter at Selinus in Cilicia. Whether he ever was formally adopted cannot be established. The army and the senate confirmed his succession, and he took office with danger threatening the empire on nearly every side.

Emperor.—Hadrian's first important act was to abandon as untenable the conquests of Trajan beyond the Euphrates (Assyria, Mesopotamia and Armenia), a recurrence to the traditional policy of Augustus. Mesopotamia and Assyria were given back to the Parthians, and the Armenians were allowed a king of their own. Some time after this there arose trouble in Dacia from the Roxolani. Whether Hadrian set out from Antioch to suppress it, or whether he had by then already reached Rome, is disputed. In any case, while he was in Dacia occurred the conspiracy of the four consulars, generals of Trajan's, discontented at the abandonment of the conquests of the last reign. The four were killed by order of the senate, and Hadrian left Turbo with a joint command of Dacia and Pannonia and hurried to Rome, where the affair had created an atmosphere of suspicion. He threw the responsibility for the executions upon the prefect of the praetorian guard, and swore that he would never punish a senator without the assent of the entire body, to which he expressed the utmost deference and consideration. Trajan's scheme for the "alimentation" of poor children was carried out upon a larger scale under a special official called *praefectus alimentorum*.

Travels Round the Empire.—The record of Hadrian's journeys¹ through all parts of the empire forms the chief authority for the events of his life down to his final settlement in the capital during his last years. They can only be briefly touched upon here. His first great journey probably lasted from 121 to 126. After traversing Gaul he visited the Germanic provinces on the Rhine, and crossed over to Britain (spring, 122), where he built the great rampart from the Tyne to the Solway, which bears his name.

¹The chronology of Hadrian's journeys—indeed, of the whole reign—is confused and obscure. In the above the article by von Rohden in Pauly-Wissowa's *Realencyclopädie* has been followed. Webster's (see Bibliog.) is the most important discussion.

(See BRITAIN: Roman.) This part of the journey was mainly occupied with military inspections. He returned through Gaul into Spain, and then proceeded to Mauretania, where he suppressed an insurrection. A war with the Parthians was averted by a personal interview with their king (123). From the Parthian frontier he travelled through Asia Minor and the islands of the Aegean to Athens (autumn, 125), where he introduced various political and commercial changes, was initiated at the Eleusinia, and presided at the celebration of the greater Dionysia. After visiting Central Greece and Peloponnesus, he returned by way of Sicily to Rome (end of 126). The next year was spent at Rome, and, after a visit to Africa, which produced measures for the encouragement of African agriculture, he set out on his second great journey (September 128). He travelled by way of Athens, where he completed and dedicated the buildings (see ATHENS) begun during his first visit, chief of which was the Olympieum. In the spring of 129 he visited Asia Minor and Syria, where he invited the kings and princes of the East to a meeting at Samosata; Chosroes of Parthia declined. Having passed the winter at Antioch, he set out for the south (spring, 130). He ordered Jerusalem to be rebuilt (see JERUSALEM) under the name of Aelia Capitolina, and made his way through Arabia to Egypt, where he restored the tomb of Pompey at Pelusium with great magnificence. After a short stay at Alexandria he took an excursion up the Nile, during which he lost his favourite Antinous. From Egypt Hadrian returned through Syria to Europe (his movements are obscure), but was obliged to hurry back to Palestine (spring, 133) to deal with the Jewish revolt that broke out in 132. (See art. JEW; also E. Schürer, *Hist. of the Jewish People*, Eng. tr., div. 1, vol. ii, p. 288; and S. Krauss in *Jewish Encyc. s.v. "Hadrian."*) For a while he probably commanded in the field himself, then in 134, leaving the conduct of affairs in the hands of Julius Severus, he returned to Rome. The remaining years of his life were spent partly in the capital, partly in his villa at Tibur. His health now began to fail, and it became necessary for him to choose a successor. There were rumours that Servianus would be appointed, but he and his grandson Fustus were put to death in 136. Why, is not known. Against the advice of his relatives and friends he adopted L. Ceionius Commodus under the name of L. Aelius Caesar, who was in a feeble state of health and died on Jan. 1, 138, before he had an opportunity of proving his capabilities. Hadrian then adopted Arrius Antoninus (see ANTONINUS PIUS) on condition that he should adopt M. Annius Verus (afterwards the emperor Marcus Aurelius) and the son of L. Aelius Caesar, L. Verus (afterwards co-emperor). Hadrian died at Baiae on July 10, 138.

Work of the Reign.—He was without doubt one of the most capable emperors who ever occupied the throne, and devoted his great and varied talents to the interests of the state. One of his chief objects was the abolition of distinctions between the provinces and the mother country, finally carried out by Caracalla, while at the same time he did not neglect reforms that were urgently called for in Italy. Provincial governors were kept under strict supervision; extortion was practically unheard of; the *ius Latii* was bestowed upon several communities; special officials were instituted for the control of the finances; and the emperor's interest in provincial affairs was shown by his personal assumption of various municipal offices. New towns were founded and old ones restored; new streets were laid out, and aqueducts, temples and magnificent buildings constructed. In Italy itself the administration of justice and the finances required special attention. Four *iuridici* of consular rank were appointed for Italy, who took over judicial functions formerly exercised by local magistrates. The judicial council (*consilarii Augusti*, later called *consistorium*), composed of persons of the highest rank (especially jurists), became a permanent body of advisers, although merely consultative. Roman law owes much to Hadrian, who instructed Salvius Julianus to draw up an *edictum perpetuum*, to a great extent the basis of Justinian's *Corpus iuris*. (See M. Schanz, *Geschichte der römischen Literatur*, iii, p. 167.) In the administration of finance, in addition to the remission of arrears already mentioned, a revision of claims was ordered to be made every fifteen years,

thereby anticipating the "indictions." (See CALENDAR; CHRONOLOGY.) Direct collection of taxes by imperial procurators was substituted for the system of farming, and a special official (*advocatus fisci*) was instituted to look after the interests of the imperial treasury. The gift of "coronary gold" (*aurum coronarium*), presented to the emperor on certain occasions, was entirely remitted in the case of Italy, and partly in the case of the provinces. The administration of the postal service throughout the empire was taken over by the state, and municipal officials were relieved from the burden of maintaining the imperial posts. Humane regulations as to the treatment of slaves were strictly enforced; the master was forbidden to put his slave to death, but was obliged to bring him before a court of justice; if he ill-treated him it was a penal offence. The custom of putting all the household to death when their master was murdered was modified. In military matters Hadrian was a strict disciplinarian, but his generosity and readiness to share their hardships endeared him to the soldiers. During his reign an advance was made in the direction of creating an organized body of servants at the disposal of the emperor by the appointment of equites to important administrative posts, without their having performed the *militiae equestres*. (See EQUITES.) Among the magnificent buildings erected by Hadrian mention may be made of the following: In the capital, the temple of Venus and Roma; his splendid mausoleum, which formed the groundwork of the castle of St. Angelo; the pantheon of Agrippa; the Basilica Neptuni; at Tibur the great villa 8 m. in extent, a kind of epitome of the world, with miniatures of the most celebrated places in the provinces. Athens, however, was the favourite site of his architectural labours; here he built the temple of Olympian Zeus, the Panhellenion, the Pantheon, the library, a gymnasium and a temple of Hera.

Hadrian was fond of the society of learned men—poets, scholars, rhetoricians and philosophers—whom he alternately humoured and ridiculed. His taste, however, was curious; he preferred Cato the elder, Ennius and Caelius Antipater to Cicero, Virgil and Sallust, the obscure poet Antimachus to Homer and Plato. As a writer he displayed great versatility. He composed an autobiography, published under the name of his freedman Phlegon; wrote speeches, fragments of two of which are preserved in inscriptions (a panegyric on his mother-in-law Matidia, and an address to the soldiers at Lambaesis in Africa). In imitation of Antimachus he wrote a work called *Catachannae*, probably a kind of miscellanea. The Latin and Greek anthologies contain about a dozen epigrams under his name. The letter of Hadrian to the consul Servianus (in Vopiscus, *Vita Saturnini*, 8) is no longer considered genuine. Hadrian's celebrated dying address to his soul may here be quoted:—

Animula vagula, blandula
Hospes comesque corporis,
Quae nunc abibis in loca
Pallidula, rigida, nudula;
Nec, ut soles, dabis jocos?

Character.—The character of Hadrian exhibits a mass of contradictions, well summed up by Spartianus (14. 11). But it is doubtful whether a good deal of this was not rather due to the defeated imaginations of his contemporaries, whom his reserved nature entirely baffled. Whatever his real character was like, the Empire under him enjoyed its golden age. The permanent marks he left, in addition to his legal and administrative reforms, were the towns he built all over the empire, and his contribution to the frontier system.

The chief ancient authorities for the reign of Hadrian are: the life by Aelius Spartianus in the *Scriptores historiae Augustae* (see AUGUSTAN HISTORY and bibliography); the epitome of Dio Cassius (lxxix.) by Xiphilinus; Aurelius Victor, *Epit.* 14, probably based on Marius Maximus; Eutropius viii. 6; Zonaras xi. 23; Suidas, s.v. Ἀδριανός; and numerous inscriptions and coins. The autobiography was used by both Dio Cassius and Marius Maximus. Modern authorities: C. Merivale, *Hist. of the Romans under the Empire*, ch. lxvi.; H. Schiller, *Geschichte der römischen Kaiserzeit*, i. 2, p. 602 (1883); J. B. Bury, *The Student's Roman Empire* (1893), where a concise table of the journeys is given; P. von Rohden, s.v. "Aelius" (No. 64) in Pauly-Wissowa's *Realencyklopädie*, i. 1 (1894); J. Dürr, *Die Reisen des Kaisers Hadrian* (1881); F. Gregorovius, *The Emperor Hadrian* (Eng. tr. by Mary E. Robinson, 1898); A. Hausrath,

Rostovtzev, *Social and Economic History of the Roman Empire* (1926).

HADRIAN'S WALL, the name usually given to the remains of the Roman fortifications which defended the northern frontier of the Roman province of Britain. It extends from Wallsend on the estuary of the Tyne to Bowness on the Solway, cir. 73½ English miles, and was erected by order of the Emperor Hadrian under Platorius Nepos, governor of Britain cir. A.D. 122–126. The complete work was not built to a single plan, but reached its final form (probably within the years stated) by three stages: (1) a series of detached forts, each holding 500 men, four miles apart, on an average, lying in front (to the north) of an earthwork (the "Vallum") which served as a visible delimitation of the civil frontier of Rome; (2) the enlargement of certain of these forts to hold 1,000 men; (3) the connection of the forts by a stone wall, and the provision of smaller fortified posts at every mile ("Mile-castles") with intervening turrets. This wall was designed rather as a fortified sentry beat than as a defensive fortification. At certain points traces have been found of a wall of turf, which preceded the stone wall; this has yet to be elucidated fully, but may be a temporary step in the development between stages 2 and 3. No definite evidence has yet been found that the wall was held by the Romans after A.D. 383. See further **BRITAIN: Roman**.

HADRUMETUM, a town of ancient Africa on the southern extremity of the *sinus Neapolitanus* (mod. Gulf of Hammamet) on the east coast of Tunisia. The site is partly occupied by the modern town of Susa (q.v.). The form of the name Hadrumetum varied much in antiquity; the Greeks called it Ἀδελμύς, Ἀδελμύριος, Ἀδελμύριος, Ἀδελμύριος: the Romans *Adrumetum*, *Adrimetum*, *Hadrumetum*, *Hadrymetum*, etc.; inscriptions and coins gave *Hadrumetum*. The town was a Phoenician colony founded by Tyrians long before Carthage (Sallust, *Jug.* 19). It became subject to Carthage, but lost none of its prosperity. Often mentioned during the Punic Wars, it was captured by Agathocles in 310, and was the refuge of Hannibal and the remnants of his army after the battle of Zama in 202. During the last Punic War it gave assistance to the Romans; after the fall of Carthage in 146 it received an accession of territory and the title of *civitas libera* (Appian, *Punica*, xciv.; *C.I.L.* i. p. 84). Caesar landed there in 46 B.C. on his way to the victory of Thapsus (*De bello Afric.* iii.; Suetonius, *Div. Jul.* lix.).

In the organization of the African provinces Hadrumetum became a capital of the province of Byzacena. It was a busy port and the centre of a fertile country. Trajan made it a Latin colony under the title of *Colonia Concordia Ulpia Trajana Augusta Frugifera Hadrumetina*; a dedication to the emperor Gordian the Good, found at Susa gives these titles to the town, and at the same time identifies it with Susa. Quarrels arose between Hadrumetum and its neighbour Thysdrus in connection with the temple of Minerva situated on the borders of their respective territories (Frontinus, *Gromatici*, ed. Lachmannus, p. 57); Vespasian when pro-consul of Africa had to repress a sedition among its inhabitants (Suetonius, *Vesp.* iv.; Tissot, *Fastes de la prov. d'Afrique*, p. 66); it was the birthplace of the emperor Albinus. At this period Hadrumetum was after Carthage, the most important town in Roman Africa. Its bishops are mentioned at the councils of 258, 348, 393 and even later. Destroyed by the Vandals in 434 it was rebuilt by Justinian and renamed Justinianopolis (Procop. *De aedif.* vi. 6). After the Arabic invasion

of the 7th century the place became the haunt of pirates. The Arabic geographer Bakri gave a description of the chief Roman buildings which were standing in his time (Bakri, *Descr. de l'Afrique*, tr. by de Slane, p. 83 et seq.). The modern town of Susa, despite its commercial prosperity, occupies only a third of the old site.

There remains a fragment of the fortifications of the Punic town and of the substructions of the Byzantine acropolis, the circus, the theatre, the water cisterns and of other buildings, notably an interesting Byzantine basilica. In the ruins have been found numerous columns of Punic inscriptions, Roman inscriptions and mosaic, among which is one representing Virgil. In the large Christian catacombs are numerous sarcophagi and inscriptions painted or engraved of the Roman and Byzantine periods. There are also Punic and Pagan-Roman cemeteries. The town had no Punic coins, but under the Roman domination there were coins from the time of the Republic. These are of bronze and bear the name of the city in abbreviations, HADR or HADRVN accompanying the head of Neptune or the Sun. We find also the names of local duumvirs. Under Augustus the coins have on the obverse the imperial effigy, and on the reverse the names and often the effigies of the pro-consuls. After Augustus the mint was closed.

HAECKEL, ERNST HEINRICH (1834–1919), German biologist, was born at Potsdam on Feb. 16, 1834. He studied medicine and science at Würzburg, Berlin and Vienna under such men as Johannes Müller, R. Virchow and R. A. Kölliker. In 1862 he became professor of comparative anatomy and director of the zoological institute at Jena, where a chair of zoology was created for him in 1865. At Jena he spent his life, with the exception of the time devoted to various tours. As a field naturalist Haeckel's extraordinary power and industry were displayed in his publications on *Radiolaria* (1862), *Siphonophora* (1869), *Monera* (1870) and *Calcareous Sponges* (1872), as well as several *Challenger* reports, viz. *Deep-Sea Medusae* (1881), *Siphonophora* (1888), *Deep-Sea Keratosa* (1889) and *Radiolaria* (1887).

Meanwhile he had become the first German biologist to give a wholehearted adherence to the doctrine of organic evolution, and Darwin himself believed that Haeckel's enthusiastic propagandism was the chief factor of the success of the doctrine in Germany. His *General Morphology* (1866) was a suggestive attempt to work out the practical application of evolution to its final results. *Natürliche Schöpfungsgeschichte* (1867, 10th ed. 1902, Eng. trans. 1892) laid particular stress on the "fundamental biogenetic law" that ontogeny recapitulates phylogeny, that the organism in its development is to a great extent an epitome of the form-modifications undergone by the successive ancestors of the species in the course of their historic evolution. Haeckel's well-known "gastraea" theory is an outcome of this generalization. He divided animal creation into the Protozoa or unicellular animals, and the Metazoa or multicellular animals. In the Metazoa the single primitive egg-cell is transformed by cleavage into a globular mass of cells (*morula*), which first becomes a hollow vesicle and then changes into the *gastrula*. The simplest multicellular animal resembles this gastrula with its two primary layers, ectoderm and endoderm, and the earliest hypothetical form of this kind, from which the higher animals are probably descended, may be called the "gastraea."

Haeckel was the first to draw up a genealogical tree of the relationship between the various orders of animals. His efforts in this direction culminated in the paper he read before the fourth International Zoological Congress, held at Cambridge in 1898, when he traced the descent of the human race in 26 stages from organisms like the still-existing *Monera*, simple structureless masses of protoplasm, and the unicellular *Protista*, through the chimpanzees and the *Pithecanthropus erectus*, which he regarded as the link between primitive man and the anthropoid apes.

Haeckel's attempt to apply the doctrine of evolution to the problems of philosophy and religion appeared in *Die Weltrütsel* (1899, Eng. trans. *The Riddle of the Universe*, 1900). Adopting an uncompromising monistic attitude, he asserted the essential unity of organic and inorganic nature. For him the chemico-physical properties of carbon in its complex albuminoid compounds are the sole and the mechanical cause of the specific phenomena of movement which distinguish organic from inorganic substances, and the first development of living protoplasm, as seen in the *Monera*, arises from such nitrogenous carbon-compounds by spontaneous generation. Psychology he regarded as merely a branch of physiology. Every living cell has psychic properties, and the psychic life of multicellular organisms is the sum-total of the psychic functions of the cells of which they are composed. Moreover, just as the highest animals have evolved from the simplest forms of life, so the highest human faculties have evolved from the soul of animals. Consequently Haeckel denied the immortality of the soul, the freedom of the will, and the existence of a personal God.

Although Haeckel occupies no serious position in the history of philosophy, there can be no doubt that he was very widely read in his own day, and that he is very typical of the school of extreme evolutionist thought. He died at Jena on Aug. 8, 1919.

Haeckel's other works include: *Die systematische Phylogenie* (1894), which has been pronounced his best book; *Anthropogenie* (1874, 5th ed. 1903, Eng. trans. 1879), dealing with the evolution of man; *Über unsere gegenwärtige Kenntnis vom Ursprung des Menschen* (1898, Eng. trans. 1898); *Der Kampf um den Entwicklungs-gedanken* (1905, Eng. trans. 1906); books of travel such as *Indische Reisebriefe* (1882, 6th ed. 1922) and *Aus Insulinde* (1901); *Kunstformen der Natur* (1904) and *Wanderbilder* (1905), reproductions of his oil paintings and water-colours. See W. Bölsche, *E. Haeckel. Ein Lebensbild* (Dresden, 1900, Eng. trans. 1906); Breitenbach, *E. Haeckel* (Odenkirchen, 1904); W. May, *Ernst Haeckel; Versuch einer Chronik seines Lebens und Werks* (Leipzig, 1909); K. Hauser, *E. Haeckel . . . seine Bedeutung für den Geisteskampf der Gegenwart* (1920). H. Schmidt has edited the *Erinnerungen und Briefe der Liebe* (1927).

HAEMATITE or **HEMATITE**, a mineral consisting of ferric oxide Fe_2O_3 (corresponding to 70% of iron). The name is derived from the Gr. *αἷμα*, "blood," in allusion to its typical colour, whence the mineral is also called *red iron-ore*. When crystallized it is often black; but the powdered mineral shows the characteristic red colour. It crystallizes in the hexagonal system with rhombohedral symmetry. Cleavage, imperfect. Hardness, 6. Sp.g., 5.2. Lustre, metallic. Nearly opaque. The brilliant lustre of the steel grey crystallized variety, often in tabular form, has given it such names as *specular iron-ore*, *looking-glass ore*, *iron-glance*. When in very thin scales and plates it is known as *micaceous iron-ore*. Scales of specular ore occur on the surface of lavas in volcanic districts. This is no doubt a sublimation product formed by the inter-action of steam and ferric chloride. Haematite is often compact or massive with a mammillated surface and an internal fibrous structure (*pencil-ore*). A reniform variety is known as *kidney-ore*. Much haematite occurs in an earthy form, when it is termed *soft red ore*. *Red ochre* or *reddle* is an earthy variety used for the preparation of the pigment having the same name. *Rouge* is another preparation made from haematite. On account of its high iron content and freedom from phosphorus, haematite constitutes a valuable iron-ore (*q.v.*). (F. H. HA.)

HAEMATOCELE, the medical term for a localized collection of blood, particularly in the tunica vaginalis or cord. It is usually the result of a sudden blow or severe strain, but may arise from disease. At first it forms a smooth, fluctuating, opaque swelling, but later becomes hard and firm. In chronic cases the walls of the tunica vaginalis undergo changes. The treatment of a case seen soon after the injury is directed towards keeping the patient at rest, elevating the parts, and applying an evaporating lotion or ice-bag. In chronic cases it may be necessary to lay open the cavity and remove the coagulum.

HAEMATOPODIDAE: see OYSTER-CATCHER.

HAEMOPHILIA, the medical term for a condition of the blood, particularly deficiency of blood platelets, and possibly also

of the vascular system, often running in families, the members of which are known as "bleeders," characterized by a disposition towards bleeding, whether with or without the provocation of an injury to the tissue. When this bleeding is spontaneous it comes from the mucous membranes, especially from the nose, but also from the mouth, bowel, and bronchial tubes. Slight bruises are apt to be followed by extravasations of blood into the tissues; the swollen joints (knee especially) of a bleeder are probably due, in the first instance, to the escape of blood into the joint cavity or synovial membrane. It is always from the smallest vessels that the blood escapes, and may do so in such quantities as to cause death in a few hours. Haemophilia occurs almost exclusively in males but is transmitted by the females of a family.

HAEMORRHAGE, a general term for an escape of blood from a blood-vessel (see BLOOD). It commonly results from injury, as the tearing or cutting of a blood-vessel, but certain forms result from disease, as in haemophilia, scurvy, and purpura. The chief varieties of haemorrhage are *arterial*, *venous*, and *capillary*. Bleeding from an artery is of a bright red colour, and escapes from the end of the vessel nearest the heart in jets synchronous with the heart's beat. Bleeding from a vein is of a darker colour; the flow is steady, and the bleeding is from the distal end of the vessel. Capillary bleeding is a general oozing from a raw surface. By *extravasation of blood* is meant the pouring out of blood into the areolar tissues, which become boggy. This is termed a *bruise* or *ecchymosis*. *Epistaxis* is a term given to bleeding from the nose. *Haematemesis* is vomiting of blood, the colour of which may be altered by digestion, as is also the case in *melaena*, or passage of blood with the faeces, in which the blood becomes dark and tarry-looking from the action of the intestinal fluids. *Haemoptysis* denotes an escape of blood from the air-passages. *Haematuria* means passage of blood with the urine.

Cessation of bleeding may take place from natural or from artificial causes. Natural arrest of haemorrhage arises from (1) the coagulation of the blood itself, (2) the diminution of the heart's action as in fainting, (3) changes taking place in the cut vessel causing its retraction and contraction. In the surgical treatment of haemorrhage minor means of arresting bleeding are: cold, which is most valuable in general oozing and local extravasations; very hot water, 130° to 160° F, a powerful haemostatic; position, such as elevation of the limb, valuable in bleeding from the extremities; styptics or astringents applied locally, as perchloride of iron, tannic acid, and others, the most valuable being suprarenal extract. In arresting haemorrhage temporarily the chief thing is to press directly on the bleeding part. The pressure to be effectual need not be severe, but must be accurately applied. If the bleeding point cannot be reached, the pressure should be applied to the main artery between the bleeding point and the heart. In small blood-vessels pressure will be sufficient to arrest haemorrhage permanently. In large vessels it is usual to pass a ligature round the vessel and tie it with a reef-knot. Apply the ligature, if possible, at the bleeding point, tying both ends of the cut vessel. If this cannot be done, the main artery of the limb must be exposed by dissection at the most accessible point between the wound and the heart, and there ligatured.

Haemorrhage has been classified as—(1) primary, occurring at the time of the injury; (2) reactionary, or within 24 hours of the accident, during the stage of reaction; (3) secondary, occurring at a later period and caused by faulty application of a ligature or septic condition of the wound. In severe haemorrhage, as from the division of a large artery, the patient may collapse and death ensue from syncope. In syncope stimulants and strychnine may be given, but they should be avoided until it is certain the bleeding has been properly controlled, as they tend to increase it. Transfusion of blood directly from the vein of a healthy person to the blood-vessels of the patient, and infusion of gum, glucose or saline solution into a vein, may be practised (see SHOCK). In the congenital condition known as *haemophilia* (*q.v.*) it is difficult to stop the flow of blood.

The effects of haemorrhage within the body are widespread, and immediate as well as delayed. As an immediate effect of loss of blood the volume of fluid within the blood-vessels and therefore

the amount entering and leaving the heart is diminished. This change of volume is rectified within a few seconds or minutes by (1) contraction of the arterioles and (2) passage of fluid from the tissues into the capillaries and venules. Hence the original volume is rapidly re-established, but the blood, for a time, is more dilute than formerly. Of the delayed changes the most noticeable concern the blood corpuscles. Young and it may be nucleated red corpuscles are found in the circulating blood and the number of leucocytes, particularly the polynuclear variety, is raised above the normal. In the bone marrow there are signs of great activity, the tissue being bright red and highly cellular. The blood pressure in the great arteries remains approximately at its normal level until about one-third of the original amount of blood has been lost, and then it falls abruptly.

HAEMORRHOIDS or **HEMORRHOIDS**, commonly called *piles*, swellings formed by the dilatation of veins of the lowest part of the bowel, or of those just outside the margin of its aperture. The former, *internal piles*, are covered by mucous membrane; the latter, *external piles*, are just beneath the skin. As the veins of the lining of the bowel become dilated they form definite bulgings within the bowel, and, at last increasing in size, escape through the anus when a motion is being passed. Growing still larger, they may come down spontaneously when the individual is standing or walking, and they are apt to be a grave source of pain or annoyance. Eventually they may remain constantly protruded—nevertheless, they are still *internal piles* because they arise from the interior of the bowel. Though a pile is sometimes solitary, there are usually several of them. They are apt to become inflamed, and the inflammation is associated with heat, pain, discharge and general uneasiness; ulceration and bleeding are also common symptoms, hence the term “bleeding piles.” The *external pile* is covered by the thin, dark-coloured skin of the anal margin. Severe pressure upon the large abdominal veins may retard the upward flow of blood to the heart and so give rise to piles; this is apt to happen in the case of disease of the liver, malignant and other tumours within the pelvis or abdomen, and pregnancy. Probably the anatomical arrangement of veins at the lower end of the rectum and habitual constipation are predisposing causes of piles. It is often said the exciting cause may be vigorous straining at stool or exposure to damp, as from sitting on the wet ground, but there is little solid evidence for the statements. Piles are often only a symptom, and in their treatment this fact should be kept in view; if the cause is removed the piles may disappear. Moreover, if they indicate the existence of cancer of the rectum the whole aspect of the case is altered. The appearance of piles or of haemorrhage assumed to be from piles for the first time in a person of middle age or over is highly suggestive of the major disease. Sometimes when a pile has been protruded, as during defaecation, it is tightly grasped by spasmodic contraction of the circular muscular fibres which guard the outlet of the bowel, and it then becomes swollen, engorged and extremely painful; the strangulation may be so severe that the blood of the vessels coagulates and the pile mortifies. This, indeed, is nature’s attempt at curing a pile, but it is distressing, and, as a rule, it is not entirely successful.

The palliative treatment of piles consists in obtaining a daily and easy action of the bowels, in rest, cold bathing, astringent injections, lotions and ointments. The radical treatment consists in their removal by operation, but this should not be contemplated until palliative treatment has failed. If, for one reason or another, no operation is to be undertaken, and the piles are troublesome, relief may be afforded by warm sponging and by sitz-baths, the pile being gently dried afterwards by a piece of soft linen, smeared with vaseline, and carefully returned into the bowel. Under surgical advice, cocaine or morphia may be brought in contact with the tender parts, either in the form of lotion, suppository or ointment. If, as often happens, blood coagulates in the vein of an external pile, the small, hard, tender swelling may be treated with anodyne fomentations, or it may be rendered insensitive by the ether spray and opened by a small incision, the clot being turned out. Diathermic treatment is often useful. The usual operation consists in strangling the pile by ligatures.

HAEMOSPORIDIA. Parasitic single-celled animals (Protozoa) which live in the red blood-corpuscles of vertebrates, and gradually destroy them. We find, therefore, among the Haemosporidia the causes of many maladies, including the organisms which cause the various kinds of malaria. (See PROTOZOA.)

HĀFIZ. Shams-ud-din Mohammed, better known by his *takhallus* or *nom de plume* of Hāfiz, one of the most famous writers of Persian lyrical poetry, was born at Shiraz, the capital of Fars, in the early part of the 8th century of the Mohammedan era (c. A.D. 1300). The exact date of his birth is uncertain, but he attained a ripe old age and died in 791 A.H. (A.D. 1388), as given in the chronogram which is engraved on his tomb. He early devoted himself to the study of poetry and theology, and also became learned in mystic philosophy, which he studied under Shaik Mahmūd ‘Attār, chief of an order of dervishes. Hāfiz afterwards enrolled himself in the same order and became a professor of Koranic exegesis in a college which his friend and patron Haji Kiwam-ud-din, the vizier, specially founded for him. This was probably the reason of his adopting the sobriquet of Hāfiz (“one who remembers”), which is technically applied to any person who has learned the Koran by heart. The restraints of an ascetic life seem to have been very little to Hāfiz’s taste, and his loose conduct and wine-bibbing propensities drew upon him the severe censure of his monastic colleagues. In revenge he satirizes them unmercifully in his verses, and seldom loses an opportunity of alluding to their hypocrisy. Hāfiz’s fame as a poet was soon rapidly spread throughout the Mohammedan world. He was, like most Persians, a Shi’ite by religion, believing in the transmission of the office of Imām (head of the Muslim Church) in the family of Ali, cousin of the prophet, and rejecting the *Hadīth* (traditional sayings) of Mohammed, which form the Sunna or supplementary code of Mohammedan ceremonial law. One of his odes which contains a verse in praise of Ali is engraved on the poet’s tomb, but is omitted by Sudi, the Turkish editor and commentator, who was himself a rigid Sunnite.

His principal work is the *Diwān*, that is, a collection of short odes or sonnets called *ghazals*, and consisting of from five to sixteen *baits* or couplets each, all the couplets in each ode having the same rhyme in the last hemistich, and the last couplet always introducing the poet’s own *nom de plume*. Hāfiz was a professed dervish and Sūfī, and his *ghazals* were in all probability published from a *takia*, and arranged with at least a view to Sufistic interpretation. At the same time it is ridiculous to suppose that the glowing imagery, the gorgeous and often tender descriptions of natural beauties, the fervent love passages, and the roystering drinking songs were composed in cool blood or with deliberate ascetic purpose. The beauty of Hāfiz’s poetry is that it is natural. It is the outcome of a fervent soul and a lofty genius delighting in nature and enjoying life; and it is the poet’s misfortune that he lived in an age and amongst a people where rigid conventionality demanded that his free and spontaneous thoughts should be recast in an artificial mould.

Besides the *Diwān*, Hāfiz wrote a number of other poems; the Leipzig edition of his works contains 573 *ghazals* (forming the *Diwān*), 42 *kit’as* or fragments, 69 *ruba’iyāt* or tetrastics, 6 *masnaviyāt* or poems in rhyming couplets, 2 *kasāid*, idylls or panegyrics, and 1 *mukhammes* or poem in five-line strophes. Other editions contain several *tar ji’-band* or poems with a refrain. The whole *Diwān* was translated into English prose by H. Wilberforce Clarke in 1891. Other selections are by S. Robinson (1875), A. Rogers (1889), J. H. McCarthy (1893) and Gertrude L. Bell (1897). The principal German versions are by von Hammer Purgstall (1812); a rhyming and rhythmical translation of a large portion of Hāfiz’s works by Vincenz von Rosenzweig of Vienna (Vienna, 1858), which contains also the Persian text and notes; *Der Diwan des Schemseddin Muhammed Hāfis*, by G. H. F. Nesselmann (Berlin, 1865), in which the rhyming system of the original is limited. Besides these, the reader may consult d’Herbelot, *Bibliothèque orientale*, article “Hāfiz”; Sir William Ouseley’s *Oriental Collections* (1797–1798); *A Specimen of Persian Poetry, or Odes of Hafiz*, by John Richardson (London, 1802); *Biographical Notices of Persian Poets*, by Sir Gore Ouseley

(Oriental Translation Fund, 1846); and an excellent article by Professor E. B. Cowell in *Macmillan's Magazine* (No. 177, July 1874); J. A. Vullers, *Vitae poetarum Persicorum* (1839, translated from Daulatshah); S. Robinson, *Persian Poetry for English Readers* (1883). The best edition of the text perhaps that edited by Hermann Brockhaus of Leipzig (1854-1856). See also H. Ethé in *Grundriss der iranischen Philologie*, II. (Strassburg, 1896); P. Horn, *Geschichte der persischen Literatur* (Leipzig, 1901).

HAFNIUM is the name given by its Danish discoverers (D. Coster and G. von Hevesy) to a metallic element which always occurs in close association with zirconium; symbol Hf, atomic number 72, atomic weight 178.6. The chemists, G. Urbain and A. Dauvillier, on the grounds of an indication of the element obtained by the former, claim the privilege of naming it *Celtium*, and references to this discussion are given under that heading. The high melting point and electronic emissivity of hafnium are the reasons for the recent issuance of two patents for its use in lamp filaments, particularly in radio tubes.

The properties of this element and its compounds are so similar to those of zirconium and its compounds that separation of the two is a matter of great difficulty, and its discovery has made necessary the revision and correction of all existing data on zirconium because all salts of zirconium are contaminated with from 1% to 5% of hafnium.

See J. H. de Boer, *Z. Anorg. Chem.*, 150, p. 210 (1926); von Hevesy, *Das Element Hafnium* (Berlin, 1927); O. Honigschmidt and E. Zintl *Berichte*, 58, p. 453 (1925).

HAFSTEIN, HANNES THORDUR (1861-1922), Icelandic statesman and poet, was born on Dec. 4, 1861. As a young man he became known as a lyrical poet. In 1901 he was elected a member of the Althing, and soon became a leader of the Home Rule party. It was chiefly owing to his influence that Denmark consented, in 1903, to the transfer of the residency of the minister for Iceland from Copenhagen to Reykjavik. On Jan. 31, 1904, Hafstein was appointed to this office and inaugurated a new era of practical reform. His first work was to arrange a telegraphic cable to Great Britain and a net of telegraphs and telephones all over the island. His efforts, however, were hampered by the extremists, who demanded greater political independence from Denmark. Their obduracy led to his resignation in 1908. On the victory of the Home Rulers in 1911, Hafstein again became minister in 1912, but had to resign in 1914 after new and fruitless efforts to effect reconciliation. He lived, however, to see the full reconciliation between the two countries in 1918, and the recognition of Iceland as an independent State in union with Denmark. He died on Dec. 13, 1922.

HAFTĀRA (lit. *conclusion*), the second or prophetic lesson (also called *Shelemta*) which ended the ancient service. These were shorter in the days of Jesus (Luke iv. 16) than at present and were accompanied by exegesis. A Spanish translation still accompanies the *Hafjāra* of the Fast of Ab in London.

BIBLIOGRAPHY.—For *Hafjāra* blessings see S. Singer's prayer book pp. 148-149 and I. Abrahams' notes in annotated edition (London, 1928). For list of *Hafjāroth* see *Jew. Enc.* (s.v.). For the history of the *Hafjāra* see I. Abrahams, *Studies in Pharisaism*, I, ch. i.; I. Elbogen, *Jüd-Gottesdienst* (Frankfurt-a-M., 1924); A. Büchler, *Jew. Quart. Rev.*, v. 464 sqq. (question of triennial cycle); G. F. Moore, *Judaism*, I, 300 sqq. (Harvard, 1927).

HAG, a word common during the 16th and 17th centuries for a female demon or evil spirit, and so particularly applied to harpies and fairies of classical mythology, and also to witches. (Ger. *Hexe*, fr. O.E. *haegtesse*.) The name is also used of an eel-like parasitic fish, *Myxine*, allied to the lamprey; of a kind of light said to appear at night; of a copse (north England and Scotland), and of a cutting in the peat of a bog.

HAGEDORN, FRIEDRICH VON (1708-1754), German poet, was born on April 23, 1708, at Hamburg, where his father was Danish minister. He was educated at the gymnasium of Hamburg, and at Jena. Returning to Hamburg in 1729, he became unpaid private secretary to the Danish ambassador in London, where he lived till 1731. In 1733 he was appointed secretary to the so-called "English Court" (*Englischer Hof*) in Hamburg, a

trading company founded in the 13th century. He died on Oct. 28, 1754. Hagedorn is the first German poet who bears unmistakable testimony to the nation's recovery from the devastation wrought by the Thirty Years' War. His light and graceful love-songs and anacreontics, with their undisguised *joie de vivre*, introduced a new note into the German lyric; his fables and tales in verse are hardly inferior in form and in delicate persiflage to those of his master La Fontaine, and his moralizing poetry re-echoes the philosophy of Horace. He exerted a dominant influence on the German lyric until late in the 18th century.

The best edition of Hagedorn's works is by J. J. Eschenburg (5 vols., Hamburg, 1800). Selections of his poetry with an excellent introduction in F. Muncker, *Anakreontiker und preussisch-patriotische Lyriker* (Stuttgart, 1894). See also H. Schuster, *F. von Hagedorn und seine Bedeutung für die deutsche Literatur* (Leipzig, 1882); W. Eigenbrodt, *Hagedorn und die Erzählung in Reimversen* (1884).

HAGEN, FRIEDRICH HEINRICH VON DER (1780-1856), German philologist, was born at Schmiedeberg, Brandenburg, on Feb. 19, 1780, and died at Berlin, where he was professor of German literature, on June 11, 1856. His numerous editions of old German poetry, notably his *Minnesinger* (Leipzig, 1838-56, 4 vols. in 5 parts), *Gesamtabenteuer* (Stuttgart, 1850, 3 vols.) and *Das Heldenbuch* (Leipzig, 1855), aroused new interest in the subject.

His correspondence with C. G. Heyne and G. F. Benecke was published by K. Dziatzko (Leipzig, 1893).

HAGEN, JOHANNES GEORG (1847-), German astronomer, was born at Bregenz on March 6, 1847. He was educated at Feldkirch, Dittion Hall, Münster and Bonn; and became director of Georgetown observatory, Washington, D.C. He left there in 1906, since when he has been director of the observatory of the Vatican, Rome. His chief work has been the study and classification of variable stars. He has also examined the dark nebulae by visual observation, and in 1920 invented the isotomeograph. His publications include: *Synopsis of Higher Mathematics*, and *Aggiunte alle carte dell' Atlas Stellarum variabilium* (Rome, 1920).

HAGEN, a town of Germany, in the Prussian province of Westphalia. Pop. (1925) 99,294. It lies at the confluence of the Ennepe with the Volme, 15 m. N.E. of Elberfeld, on the main line to Brunswick and Berlin, and at the junction of important railway lines, connecting it with the principal towns of the Westphalian iron district. Hagen has extensive iron and steel works, large cotton print works, manufactures of leather, paper, tobacco, and iron and steel wares, sugar, breweries and distilleries. There are large limestone quarries in the vicinity and also an alabaster quarry.

HAGENAU: see HAGUENAU.

HAGENBACH, KARL RUDOLF (1801-1874), German church historian, was born on March 4, 1801 at Basel, where his father was a practising physician, and died there on June 7, 1874. In 1824 he became professor extraordinarius at Basel, and in 1829 professor ordinarius of theology. He supported "mediation theology" (*Vermittelungstheologie*), based upon the fundamental conceptions of Herder and Schleiermacher. Hagenbach was much less revolutionary than were many others of his school. He sought to maintain the old confessional documents, and to make the objective prevail over the purely subjective manner of viewing theological questions.

His works include *Encyclopädie u. Methodologie der theol. Wissenschaften* (1833); *Lehrbuch der Dogmengeschichte* (1840-41, 5th ed., 1867; English trans., 1850); *Vorlesungen über die Kirchengeschichte von der ältesten Zeit bis zum 19ten Jahrhundert* (7 vols., 1868-72). See E. Stähelin, *Karl Rudolf Hagenbach* (1875).

HAGENBACH, PETER VON (c. 1420-1474), Burgundian courtier and governor of Alsace. A member of a noble family of the Sundgau, he was in 1453 in the service of Duke John I. of Cleves. After serving under various princes he joined the court of Charles the Bold (q.v.), duke of Burgundy, in 1469, and was made governor of the territories on the upper Rhine mortgaged to him by Sigismund of Austria. His government in Alsace was harsh and the towns of Rheingelden, Seckingen, Laufenburg and Waldshut rose in revolt against him. Other towns joined in the revolt. Hagenbach, who had no help from Charles except a few

Picard soldiers, was seized on April 10, 1474, at Breisach, and imprisoned. Meanwhile Sigismund appeared at Basle to recover the mortgaged territories. The allies were determined on the death of the hated Hagenbach. He was tortured on May 5, and on May 9 was brought before a court at Breisach drawn from Strasbourg, Basle and other cities. He was condemned to death and beheaded the same evening.

HAGENBECK, CARL (1844-1913), wild-animal collector and dealer, was born at Hamburg. In 1848 his father purchased some seals and a Polar bear brought to Hamburg by a whaler, and subsequently acquired other wild animals. Carl was given the whole collection in 1865, and extended the business so that in 1873 he had to erect large buildings. In 1875 he began to exhibit animals representative of many countries throughout all the large cities of Europe. The educational value of these exhibitions was recognized by the French government, which in 1891 awarded him the diploma of the Academy. He died at Hamburg on April 14, 1913. Hagenbeck's Zoo at Stellingen, near Hamburg, is renowned for its planning which, like that of Yellowstone National Park (*q.v.*), enables spectators to observe the animals apparently in their natural surroundings and at liberty.

HAGERSTOWN, a city of Maryland, U.S.A., 72m. W.N.W. of Baltimore, near Antietam creek; the county seat of Washington county. It is on Federal highways 11 and 40, and is served by the Baltimore and Ohio, the Norfolk and Western, the Pennsylvania, and the Western Maryland railways, and by inter-urban trolleys and motor-coach lines. The population was 28,064 in 1920 (93% native white) and was estimated locally at 36,500 in 1928. It is an active business centre for the rich agricultural environs, and has substantial manufacturing industries, with an output in 1925 valued at \$17,542,327. Among the leading manufactures are pipe organs, paper, flour, sash, doors, spokes, furniture, silk and knitted goods, shoes, chemicals and automobiles. Hagerstown was laid out in 1761 by Capt. Jonathan Hager who had received a patent to 200ac. from Lord Baltimore in 1739; it was incorporated in 1791. It was an important station on the old National (or Cumberland) road.

HAGERUP, GEORG FRANCIS (1853-1921), Norwegian statesman and jurist, was born at Horten on Jan. 22, 1853. Educated at Oslo, Munich, Leipzig and Paris, he began to lecture on law at Oslo in 1879. Hagerup, who belonged to the party of the Right, was minister of justice (1893-95) in Stang's cabinet, and headed the coalition ministry of 1895-98. At this time the question of separate consular representation for Norway was acute, but a joint Swedish-Norwegian committee reached no result. Hagerup was again premier in 1903-05, and himself went to Stockholm to seek a settlement of outstanding questions. He failed and resigned office in March. Subsequently Hagerup was minister at Copenhagen. He wrote some important works on Scandinavian law, and *Ret og Kultur i det nittende Aarhunderte* (1919). In 1903 he became a member of The Hague court of arbitration. He died on Feb. 8, 1921.

HAG-FISH, BORER or **GLUTINOUS HAG** (*Myxine*), one of the *Cyclostomata* (*q.v.*). It is elongated in shape and feeds on fish, eating its way into them and devouring everything but the skin, skeleton, and nervous system. It is found in the temperate seas, and is especially abundant on the east coast of Scotland and the coast of California, where it causes considerable damage to the fisheries. It secretes a glutinous substance in large quantities. (See FISH.)

HAGGĀDAH ("narrative"), or 'AGĀDA, and HALĀKHĀH ("conduct") are two varieties of Midrash (*q.v.*). The former constitutes the poetical element and the latter the legal, though the two often are closely connected. The theory of H. P. CHAJES (*Markus-Studien*, 1899, p. 11) that Mark i. 22 ("He taught in parables and not as the Scribes," reading מִפְּסָלִים for מִפְּסָלִים) implies that Jesus reintroduced Haggādah, hitherto almost unknown, as an antithesis to the Halākhah of the Scribes, is controverted by I. Abrahams (*Studies in Pharisaism*, i. p. 94). Haggādah may be traced back to the Old Testament parables and has always been popular. The Talmud abounds in Haggādah and the Haggādīc

passages were extracted repeatedly, finally by Jacob b. Solomon ibn Habib, whose *'Eyn Ya'aqobh* has had many editions. The present Halākhah is mostly of Pharisaic authority. To regard it as nothing but hair-splitting casuistry is incorrect: many enactments are ordinary juridical requirements, common to most systems of Law. Others, especially those generally cited as quibbles, are mere exercises of logic, of purely academic interest. That there are as well far-fetched decisions in this as in every other code is true, but these are not disproportionately numerous. Very often the Pharisees who followed the spirit had to find scriptural authority for legislation opposed by the conservative Sadducees, who kept to the letter of the Scriptures: often a primitive custom so modified needed biblical support. The change of the *lex talionis* into covenanted compensation is an instance. It is not the legislation that is far-fetched but the scriptural peg from which the legislation hung. After the completion of the Talmud the Halākhah was soon codified; just as the Haggādah was extracted, so in a parallel manner, was the Halākhah. Examples are Simon Kayyara's *Halākhoth Gedōloth* (9th century), the code of Isaac al-Fāsi (1013-1103), the *Strong Hand* of Moses Maimonides (published in 1180), the *'Arba' Turim* of Jacob ben Asher (1283-1340), the *Ṣemag* of Moses v. Jakob of Coucy (c. 1235) and the *Shulḥan 'Arūkh* of Joseph Caro (1488-1545).

See relevant articles in *Jew. Enc.*, and I. Abrahams, *Short Hist. Jew. Lit.* (1906).

HAGGAI, the tenth in order of the "minor prophets," whose writings are preserved in the Old Testament. The book contains four short prophecies delivered between September and December of the second year of Darius; that is, Darius Hystaspis (521-485 B.C.). The language of the prophet in ii. 3 has suggested that he was so old as to have seen the Temple of Solomon which had been destroyed in 586 B.C. This would agree with the shortness of the period covered by his book, and with the fact that his contemporary Zechariah, who began to prophesy in the same autumn, afterwards appears as the leading prophet in Jerusalem (Zech. vii. 1-4).

In his first prophecy (i. 1-11) Haggai addresses Zerubbabel and Joshua, rebuking the people for leaving the temple unbuilt. The prevalent famine and distress are due to Yahweh's indignation: let them build the house and Yahweh will take pleasure in it and acknowledge the honour paid to Him. The people thereupon began to work at the temple, strengthened by the prophet's assurance that the Lord was with them (i. 12-15). In a second prophecy (ii. 1-9) delivered in the following month, Haggai forbids the people to be disheartened by the apparent meanness of the new temple. The silver and gold are the Lord's. He will soon shake all nations and their choicest gifts will be brought to adorn His house. Its glory shall be greater than that of the former temple, and in this place He will give peace. A third prophecy (ii. 10-19) contains a promise, enforced by a figure drawn from the priestly ritual, that God will remove famine and bless the land from the day of the foundation of the temple onwards. Finally, in ii. 20-23, Zerubbabel is assured of God's special love and protection in the impending catastrophe of kingdoms and nations to which the prophet had formerly pointed as preceding the glorification of God's house on Zion.

The characteristic features of the book are three. (1) The importance assigned to the personality of Zerubbabel, who, though a living contemporary, is marked out as the Messiah. The hopes fixed on Zerubbabel, the chosen of the Lord, dear to Him as His signet ring (*cf.* Jer. xxii. 24), indicate the importance of the house of David. But in the book of Zechariah Zerubbabel is falling into the background, and the kingship is yielding to the priesthood. After the foundation of the temple Zerubbabel disappears from history and lives only in legend, which continued to busy itself with his story, as we see from the apocryphal book of Esdras. (2) An almost sacramental significance is attached to the temple. Haggai argues that material prosperity was conditioned by zeal in worship: the prevalent suffering was an indication of divine anger. While the temple lay waste, the people and all their works and offerings were unclean (ii. 14). In this Haggai stands in contrast to those prophets who warn their hearers

against attaching intrinsic importance to the temple (e.g., Isa. lxvi. 1), and he betrays his affinity with Ezekiel, who taught that it was by the possession of the sanctuary and priesthood that Israel was sanctified (Ezek. xxxvii. 28). Finally (3) what is the cause of the indifference of the Jews to the desolate condition of their sanctuary? Neither Haggai nor his contemporary Zechariah mentions or implies any return of exiles from Babylon, and the view is accordingly held that the return under Cyrus described in Ezra i-iv. is unhistorical, and that the community addressed by Haggai consisted, in the main, of the Judaeans that had been left in Jerusalem and its neighbourhood after the majority had gone into exile or fled to Egypt (Jer. xliii.). (See JEWS.)

From the prophecies of Haggai and Zechariah it would never be supposed that some 50,000 Jews had returned when Cyrus became king of Babylon and showed high favour to the exiles (Ezra i.). Even if their enthusiasm had melted away under the stress of bad seasons, the enmity of jealous neighbours, and other troubles, the contrast which Zechariah draws between Yahweh's past wrath and his imminent intervention on behalf of his people, points to the approach of new conditions. And in fact the Jews everywhere were not likely to have been unmoved by the revolts which broke out in the Persian empire at the accession of Darius. Haggai accordingly sees a shaking of the nations which seemed destined to spread; and with the characteristic tendency of Hebrew prophecy to estimate history only in its bearing upon the destiny of Yahweh's people, he looks for an age when Yahweh's enemies would be overthrown, there would be peace, Yahweh's temple would be enriched by willing nations, and Zerubabel would occupy the highest place of honour. (See JEWS.)

BIBLIOGRAPHY.—Haggai is usually treated along with Zechariah or with the rest of the minor prophets: see the bibliographies to these. (W. R. S.; S. A. C.)

HAGGARD, SIR HENRY RIDER (1856-1925), English novelist, was born at Bradenham Hall, Norfolk. At the time of the first annexation of the Transvaal (1877), he was on the staff of the special commissioner, Sir Theophilus Shepstone, and then became a master of the High Court there. After the cession of the Transvaal to the Dutch he returned to England and read for the bar. He gained a great popular success with the novels *Dawn* (1884); *The Witch's Head* (1885), which contains an account of the British defeat at Isandhlwana; *King Solomon's Mines* (1886), suggested by the Zimbabwe ruins; and *She* (1887), another fantastic African story. The scene of *Jess* (1887) and of *Allan Quatermain* (1888) was also laid in Africa. A long list of other stories followed. Haggard showed great interest in rural and agricultural questions, being a practical gardener and farmer on his estate in Norfolk. He dealt with land questions in *Rural England* (2 vols., 1902); the report of an inquiry into colonial land settlement, in *The Poor and the Land* (1905), with suggestions for a scheme of national land settlement in Great Britain itself; and in *Rural Denmark and its Lessons* (1911). Haggard was knighted in 1912. He died in London on May 14, 1925.

HAGGIS. A dish consisting of a calf's, sheep's or other animal's heart, liver and lungs, and also sometimes of the smaller intestines, boiled in the stomach of the animal with seasoning of pepper, salt, onions, etc., chopped fine with suet and oatmeal. It is considered peculiarly a Scottish dish, but was common in England till the 18th century. The derivation of the word is obscure.

HAGIOLOGY, that branch of the historical sciences which is concerned with the lives of the saints (Gr. ἅγιος, saint, λόγος, discourse). If hagiology be considered merely in the sense in which the term has come to be understood in the later stages of its development, i.e., the critical study of hagiographic remains, there would be no such science before the 17th century. But the bases of hagiology may fairly be said to have been laid at the time when hagiographic documents, hitherto dispersed, were first brought together into collections. The oldest collection of this kind, the *συναγωγή τῶν ἀρχαίων μαρτυρίων* of Eusebius, to which the author refers in several passages in his writings (*Hist. Eccl.*, v. proem 2; v. 20. 5), and which has left more than one trace in Christian literature, is unfortunately lost in its entirety.

The *Martyrs of Palestine*, as also the writings of Theodoret, Palladius and others, on the origins of the monastic life, and, similarly, the *Dialogues* of St. Gregory (Pope Gregory I.), belong to the category of sources rather than to that of hagiologic collections. The *In gloria martyrum* and *In gloria confessorum* of Gregory of Tours are valuable for the sources used in their compilation. The most important collections are those which comprise the Acts of the Martyrs and the lives of saints, arranged in the order of the calendar. In the Greek Church these are called menologies (from Gr. μῆν, month, λόγος, discourse), and their existence can be traced back with certainty to the 9th century (Theodore of Studium, *Epist.* i. 2). One of them, the menology of Metaphrastes, compiled in the second half of the 10th century, enjoyed a universal vogue (see SYMEON METAPHRASTES). The corresponding works in the Western Church are the *passionaries* or *legendaries*, varieties of which are dispersed in libraries and have not been studied collectively. They generally draw from a common source, the Roman legendary, and the lives of the local saints, i.e., those specially honoured in a church, a province or a country.

Development in 16th Century.—Hagiology entered on a new development with the publication of the *Sanctorum priscorum patrum vitae* (Venice and Rome, 1551-1560) of Aloysius Lippomano (Lippomano), bishop of Verona. As a result of the co-operation of humanist scholars a great number of Greek hagiographic texts became for the first time accessible to the West in a Latin translation. The Carthusian, Laurentius Surius, carried on the work of Lippomano, completed it, and arranged the materials strictly in the order of the calendar (*De probatis sanctorum historiis*, Cologne, 1570-1575). What prevents the work of Surius from being regarded as an improvement upon Lippomano's is that Surius thought it necessary to retouch the style of those documents which appeared to him badly written, without troubling himself about the consequent loss of their documentary value.

The actual founder of hagiologic criticism was the Flemish Jesuit, Heribert Rosweyde (d. 1629), who, besides his important works on the martyrologies (see MARTYROLOGY), published the celebrated collection of the *Vitae patrum* (Antwerp, 1615), a veritable masterpiece for the time at which it appeared. It was he, too, who conceived the plan of a great collection of lives of saints, compiled from the manuscripts and augmented with notes, from which resulted the collection of the *Acta sanctorum* (see BOLLANDISTS). This last enterprise gave rise to others of a similar character but less extensive in scope.

Present Status.—To realize the present state of hagiology, the *Bibliotheca hagiographica*, both Latin and Greek, published by the Bollandists, and the *Bulletin hagiographique*, which appears in each number of the *Analecta Bollandiana* (see BOLLANDISTS), must be consulted. Thanks to the combined efforts of a great number of scholars, the classification of the hagiographic texts has in recent years made notable progress. The criticism of the sources, the study of literary styles, and the knowledge of local history now render it easier to discriminate in this literature between what is really historical and what is merely the invention of the genius of the people or of the imagination of pious writers (see H. Delehaye, *Les Légendes hagiographiques*, 2nd ed., pp. 121-141, Brussels, 1906 and art. "Hagiography" in the *Catholic Encyclopaedia*). "Though the lives of saints," says a recent historian, "are filled with miracles and incredible stories, they form a rich mine of information concerning the life and customs of the people. Some of them are 'memorials of the best men of the time written by the best scholars of the time.'" (C. Gross, *The Sources of Literature of English History*, p. 34, 1900.)

HAGIOSCOPE, in architecture, any opening, usually oblique, through the side or front walls of a church chancel to enable the congregation in transepts, chapels or other portions of the church, from which the altar would not otherwise be visible, to witness the elevation of the host during mass. Similar openings are sometimes furnished to allow an attendant to ring the sanctus bell at the proper time, or to permit someone in a vestry vision of the service so that he can notify the bell ringer. Hagioscopes or squints (q.v.) are more common in England than on the continent of Europe.

HAGONOY, a municipality (with 15 *barrios* or districts) of the province of Bulacan, Luzon, Philippine Islands, near Manila bay on the west branch of the delta of Pampanga river, about 25 m. N.W. of Manila. It was founded in 1581. Pop. (1918) 22,490. It is in the midst of a rich agricultural region, producing corn, sugar and a little coffee. Alcohol is made in considerable quantities from the fermented juice of the *nipa* palm, which grows in the neighbouring swamps; the leaves are used to make nipa thatch. Fishing is one of the chief industries. The women are famous for their skill in weaving native fabrics. Hat making, tanning and furniture making are among the other industries. In 1918, it had 5 manufacturing establishments and 100 household industry establishments with outputs valued at 803,900 and 41,600 pesos respectively. Of the 16 schools, 10 were public. The language spoken is Tagalog.

HAGUE, THE (in Dutch, *'s Gravenhage*, or, abbreviated, *den Haag*; in Fr. *La Haye*; and in Late Lat. *Haga Comititis*), the chief town of the province of South Holland, about 2½ m. from the sea. It lies on the main railway line from Rotterdam to Leiden and has tramways connecting it with Scheveningen and the Hook of Holland. It is situated on a branch of the main canal from Rotterdam to Amsterdam. Pop. (1926), 408,634.

The history of The Hague is in some respects singular. In the 13th century it was no more than a hunting-lodge of the counts of Holland, but Count Floris V. made it his residence and it thus became the seat of the supreme court of justice of Holland and the centre of the administration, and from the time of William of Orange onward the meeting-place of the states-general. It did not receive the status of a town, however, until early in the 19th century.

The Hague is the chief town of the province, the usual residence of the court and diplomatic bodies and the seat of the Government, the states-general, the high council of the Netherlands, the council of State and the chamber of accounts. It has grown very largely in modern times, especially on the west, where it stands higher, on more sandy soil, the south-eastern half of the town comprising the poorer and the business quarters.

The mediaeval-looking group of Government buildings situated in the Binnenhof (or "inner court") represent both historically and topographically the centre of The Hague. Close by lies the entrance to the Haagsche Bosch, or the wood, on one side of which is situated the deer-park, and a little beyond on the other the zoological gardens (1862). In the Noordeinde is situated the royal palace, which was purchased by the States in 1595, rebuilt by the stadtholder William III., and extended by King William I. in the beginning of the 19th century. In front of the building is a statue of William I. of Orange. The Binnenhof was once surrounded by a moat, and is still entered through ancient gateways. The oldest portion was founded in 1249 by William II., count of Holland, whose son, Floris V., enlarged it and made it his residence. The old hall of the knights, now containing the archives of the home office, is the historic chamber in which the States of the Netherlands abjured their allegiance to Philip II. of Spain, and in front of which Johan van Oldenbarnevelt was executed in 1619. Close by on the one side are the courts of justice, and on the other the first and second chambers of the states-general. In the adjoining Buitenhof, or "outer court," is the old Gevangen Poort, or prison gate (restored 1875), consisting of a tower and gateway. Here Cornelis and Jan de Witt were killed by the mob in 1672.

The Mauritshuis was built in 1633-44 by Count John Maurice of Nassau, governor of Brazil, and contains the famous picture gallery of The Hague. Other artistic collections in The Hague are the municipal museum (*Gemeente museum*), the museum Meermanno-Westreenianum, containing some interesting mss. and specimens of early typography, and the Mesdag museum. The royal library (1798) contains some early illuminated mss., a valuable collection of coins, medals and antique gems. The Groote Kerk of St. James (15th and 16th centuries) has some old stained glass, a carved wooden pulpit (1550) and some escutcheons of the Knights of the Golden Fleece, placed here after the chapter of 1456. The Nieuwe Kerk, or new church (first half 17th cen-

tury), contains the tombs of the brothers De Witt and of the philosopher Spinoza. Spinoza is further commemorated by a monument in front of the house in which he died in 1677. The town hall (built in 1565 and restored and enlarged in 1882) contains an historical picture gallery. The other principal buildings are the provincial Government offices and the ethnographical institute of the Netherlands Indies with a fine library. The chief industries of the town are iron casting, copper and lead smelting, cannon founding, the manufacture of furniture and carriages, liqueur distilling, lithographing and printing.

The Hague wood is composed chiefly of oaks and alders and beech-trees. Together with the Haarlem wood it is thought to be a remnant of the forest which once extended along the coast. In the wood is the royal villa called the Huis ten Bosch, or "house in the wood." This villa was built in the middle of the 17th century, and wings were added to it by Prince William IV. in 1748. The chief room is the richly decorated Orange Saloon, in which the International Peace Conference had its sittings in the summer of 1899. The collections in the Chinese and Japanese rooms, and the grisailles in the dining-room painted by Jacobus de Wit (1695-1754), are also noteworthy.

In the latter part of the 17th and the first half of the 18th century The Hague was the centre of European diplomacy. Among the many treaties and conventions signed here may be mentioned the treaty of the Triple Alliance (Jan. 23, 1688) between England, Sweden and the Netherlands; the concert of The Hague (March 31, 1710) between the emperor, England and Holland, for the maintenance of the neutrality of the Swedish provinces in Germany during the war of the northern Powers against Sweden; the Triple Alliance (Jan. 4, 1717) between France, England and Holland for the guarantee of the Treaty of Utrecht; the treaty of peace (Feb. 17, 1717) between Spain, Savoy and Austria, by which the first-named acceded to the principles of the Triple Alliance; the treaty of peace between Holland and France (May 16, 1795); the first "Hague Convention," the outcome of the "peace conference" assembled on the initiative of the emperor Nicholas II. of Russia (July 27, 1899), and the series of conventions, the results of the second peace conference (June 15-Oct. 18, 1907).

In 1899 the International Court of Arbitration or Hague Tribunal was established and in 1913 its seat, the Palace of Peace, was dedicated. In 1910 the arbitration tribunal of the North Atlantic fisheries sat here. A committee of the Council of the League of Nations met at The Hague in 1920 to frame a scheme for a permanent court of international justice. This court was created by an international agreement concluded at Geneva late in the same year and it has its seat at The Hague.

HAGUE CONFERENCES, the two international conferences held at The Hague in 1899 and 1907, and known as Peace Conferences. Both were organized at the instance of the emperor Nicholas II. of Russia. The chief object of the first conference, as set out in the note of Count Mouraviev, the Russian minister of foreign affairs (Jan. 11, 1899), was to arrive at an "understanding not to increase for a fixed period the present effectiveness of the armed military and naval forces, and at the same time not to increase the budgets pertaining thereto; and a preliminary examination of the means by which even a reduction might be effected in future in the forces and budgets above mentioned." The conference, which was attended by representatives of 26 states, sat from the 18th of May to the 29th of July, 1899.

When the subject of excessive armaments came up for discussion, the objections of the German military delegate led to its abandonment. Three momentous conventions were adopted, I. for the pacific settlement of international disputes; II. in relation to the laws and customs of war by land; III. for the adaptation to maritime warfare of the principles of the Geneva Convention (*q.v.*) of the 22nd of August, 1864.

Three declarations on the following matters were also adopted: *a.* Prohibition of the launching of projectiles and explosives from balloons or by other similar new methods. *b.* Prohibition of the use of projectiles the only object of which is the diffusion of asphyxiating or deleterious gases. *c.* Prohibition of the use of

bullets which expand or flatten easily in the human body, such as bullets with a hard envelope, of which the envelope does not entirely cover the core, or is pierced with incisions.

Great Britain signed and became a party to the three Conventions. Other resolutions having for their object the promotion of international peace and the humane conduct of war were also passed.

The Conference of 1907, which was attended by representatives of 44 States, sat from June 15 to Oct. 18. In spite of the resolution and *cognu* on armaments handed down from the Conference of 1899 this subject was waived, but still more important conventions than in 1899 were adopted on other matters. These were in reference to the following questions: I. the pacific settlement of international disputes; II. the limitation of the employment of force for the recovery of contract debts; III. the commencement of hostilities; IV. the laws and customs of war on land; V. the rights and duties of neutral powers and persons in war on land; VI. the status of enemy merchant-ships at the outbreak of hostilities; VII. the conversion of merchant-ships into war-ships; VIII. the laying of automatic submarine contact mines; IX. bombardment by naval forces in time of war; X. the adaptation of the principles of the Geneva Convention to maritime war; XI. restrictions on the exercise of the right of capture in maritime war; XII. the establishment of an international prize court; XIII. the rights and duties of neutral powers in maritime war; XIV. declaration prohibiting discharge of projectiles, etc., from balloons.

A draft Convention relative to the creation of a judicial arbitration court was also drawn up in connection with the first of the four following *voeux*:—

1. The Conference calls the attention of the signatory powers to the advisability of adopting the annexed draft convention for the creation of a judicial arbitration court, and of bringing it into force as soon as an agreement has been reached respecting the selection of the judges and the constitution of the court.

2. The Conference expresses the opinion that, in case of war, the responsible authorities, civil as well as military, should make it their special duty to ensure and safeguard the maintenance of pacific relations, more especially of the commercial and industrial relations between the inhabitants of the belligerent states and neutral countries.

3. The Conference expresses the opinion that the powers should regulate, by special treaties, the position, as regards military charges, of foreigners residing within their territories.

4. The Conference expresses the opinion that the preparation of regulations relative to the laws and customs of naval war should figure in the programme of the next conference; and that in any case the powers may apply, as far as possible, to war by sea the principles of the Convention relative to the laws and customs of war on land. (See LONDON, CONFERENCES OF; BLOCKADE; CONTRABAND; INTERNATIONAL LAW.)

HAGUENAU, a town of France, and capital of an arrondissement in the department of Bas-Rhin, in the middle of the Haguenau Forest, on the Moder, and on the railway from Strassburg to Weissenburg, 10 m. N.N.E. of the former city. Pop. (1926) 13,503. Haguenau owes its origin to the erection of a hunting lodge by the dukes of Swabia (12th cent.). The emperor Frederick I. surrounded it with walls and gave it town rights in 1154. On the site of the hunting lodge he founded an imperial palace, in which were preserved the jewelled imperial crown, sceptre, imperial globe, and sword of Charlemagne. Subsequently it became the seat of the *Landvogt* of Haguenau, the imperial *advocatus* in Lower Alsace. Richard of Cornwall, king of the Romans, made it an imperial city in 1257. In 1648 it came into the possession of France, and in 1673 Louis XIV. razed the fortifications. In 1675 it was captured by imperial troops, but in 1677 it was retaken by the French and nearly all destroyed by fire. From 1871–1918 it belonged to Germany and in 1918 it became French once more. It has two ancient churches, that of St. George built by Emperor Conrad in 1137, and one built in the 13th century. The principal industries are wool and cotton spinning, and the manufacture of porcelain, earthenware, boots, soap, casks, spark-

ling wines and beer. There is also considerable trade in hops, vegetables and cattle. Haguenau is the seat of a subprefect.

HAHN, AUGUST (1792–1863), German divine, was born on March 27, 1792, near Eisleben, and studied at Leipzig. In 1819 he was nominated *professor extraordinarius* of theology and pastor of Altstadt in Königsberg, and in 1820 received a superintendency in that city. In 1822 he became *professor ordinarius* and in 1826 removed as professor of theology to Leipzig. There he published two treatises: *De rationalismi qui dicitur vera indole et qua cum naturalismo contineatur ratione* (1827), and also of an *Offene Erklärung an die Evangelische Kirche zunächst in Sachsen u. Preussen* (1827), in which he sought to convince the rationalists that it was their duty voluntarily and at once to withdraw from the national church. In 1833 Friedrich Wilhelm III. summoned him to Breslau as theological professor and consistorial councillor, and in 1843 he became “general superintendent” of the province of Silesia, where he reintroduced the Augsburg Confession. He died at Breslau on May 13, 1863. His *Lehrbuch des christlichen Glaubens* (1828, 2nd. [amended] ed. 1857) explains his position. Among his other works the most important is *Bibliothek der Symbole und Glaubens regeln* (1842; 3rd ed. 1897).

HAHNEMANN, SAMUEL CHRISTIAN FRIEDRICH (1755–1843), German physician and founder of “homoeopathy,” was born at Meissen, Saxony, on April 10, 1755. He studied medicine at Leipzig and Vienna and settled in Leipzig in 1789. In the following year, while translating W. Cullen’s *Materia medica* into German, he was struck by the fact that the symptoms produced by quinine on the healthy body were similar to those of the disordered states it was used to cure. This observation led him to assert the truth of the “law of similars,” *similia similibus curantur* or *curentur*—i.e., diseases are cured (or should be treated) by those drugs which produce symptoms similar to them in the healthy. He promulgated his new principle in a paper published in 1796 in C. W. Hufeland’s *Journal*, and four years later, convinced that drugs in much smaller doses than were generally employed effectually exerted their curative powers, he advanced his doctrine of their potentization or dynamization. His chief work, *Organon der rationellen Heilkunde* (1810), contains an exposition of his system, which he called homoeopathy (*q.v.*). His *Reine Arzneimittellehre* (six vols., 1811) detailed the symptoms produced by “proving” a large number of drugs; i.e., by systematically administering them to healthy subjects. In 1821 the hostility of established interests, and especially of the apothecaries, forced him to leave Leipzig, and at the invitation of the grand duke of Anhalt-Cöthen he went to live at Cöthen. Fourteen years later he removed to Paris, where he practised until his death on July 2, 1843. Statues were erected to his memory at Leipzig in 1851 and at Cöthen in 1855. His other works are: *Fragmenta de viribus medicamentorum positivis* (1805) and *Die chronischen Krankheiten* (1828–30).

See the article HOMOEOPATHY; also Albrecht, *Hahnemann’s Leben und Werke* (Leipzig, 1875); Bradford, *Hahnemann’s Life and Letters* (Philadelphia, 1895).

HAHN-HAHN, IDA, COUNTESS VON (1805–1880), German author, was born at Tressow, Mecklenburg-Schwerin, on June 22, 1805, daughter of count Karl Friedrich von Hahn (1782–1857). She married in 1826 her wealthy cousin count Adolf von Hahn-Hahn. The marriage was unhappy, and in 1829 she procured a divorce. The countess travelled, produced some volumes of poetry indicating true lyrical feeling, and in 1838 appeared as a novelist with *Aus der Gesellschaft*, a title given to a whole series of her novels, the book originally so entitled being renamed *Ida Schönhof*. The countess’s patrician affectations at length drew upon her the merciless ridicule of Fanny Lewald in a parody of her style entitled *Diogenes, Roman von Iduna H . . . H . . .* (2nd ed., 1847), and after the revolution of 1848 she retired to a convent. *Ulrich und Gräfin Faustine* (1841) are her best works. She died at Mainz on Jan. 12, 1880.

See her *Gesammelte Werke* (Regensburg, 45 vols., 1903–04) with an introduction by O. von Schaching. See also A. Jacoby, *Ida Gräfin Hahn-Hahn* (Mainz, 1894).

HAI (939-1038), Jewish Talmudical scholar, was born in 939. He was educated by his father Sherira, gaon of Pumbeditha (Pumbedita), whom he succeeded in this office in 998. He died on March 28, 1038. Hai is famous chiefly for his answers to problems of ritual and civil law, in which he stresses custom and tradition, provided no infringement of the law were involved, and was essentially conservative in theology. He also composed treatises on Talmudic law, commentaries on the Mishnah, a dictionary of difficult terms in the Bible, Targum and Talmud and possibly a few of the poems which have since been attributed to him. He was well versed in Plato and Aristotle and in Arabic literature.

See Steinschneider, *Hebr. Übersetz.* and article in *Jewish Encyclopedia*.

HAIBAK, a town and khanate in Afghan Turkistan famed in Persian legend. The valley of Haibak, which is 3,100 ft. above sea level, is fertile and richly cultivated. The inhabitants call themselves Jagatais, a Turki race, though now generally mixed with Tajiks and speaking Persian. In the neighbourhood of Haibak are some very typical Buddhist ruins. Haibak derives its importance from its position on the main line of communication between Kabul and Afghan Turkestan.

HAIDA, the natives of Queen Charlotte islands, B.C. The Kaigani are an 18th century offshoot on Prince of Wales island. With the Tlingit and Tsimshian, the Haida constitute the Indians that have carried the peculiar native culture of the North Pacific coast (*q.v.*) to its highest pitch. Their speech, usually considered distinct, has been linked with Tlingit (*q.v.*) and Athabascan (*q.v.*) into a proposed larger Na-Dene family. In 1841, after decline had begun, the population was estimated at 8,300; in 1880, 2,000-2,800; in 1905, 900, and in 1925, 600-700.

HAIDER, KARL (1846-1912), German landscape painter, was born in 1846. He studied at Munich under Anschütz and was a contemporary and friend of Leibe, who painted his portrait in a picture called "The Art Critics" in 1868. Although he lived and worked in the midst of genre painters, Haider turned to landscape and became a great linear stylist. He settled beside the Schliersee, at the foot of the Alps, and the lake inspired much of his best work. His remarkable smoothness of line lent austerity to his pictures, which usually convey an impression of intense stillness.

HAIDINGER, WILHELM KARL, RITTER VON (1795-1871), Austrian mineralogist, geologist and physicist, was born at Vienna on Feb. 5, 1795. His father, Karl Haidinger, contributed largely to the development of mineralogical science in the latter half of the 18th century. He studied under Mohs at Graz and Freiberg, spent some years in Edinburgh, and made a tour of northern Europe. He then became scientific director of his brothers' porcelain works, and then succeeded Mohs at Vienna as counsellor of mines. His lectures on mineralogy were printed as *Handbuch der bestimmenden Mineralogie* (1845; tables, 1846). He was director of the imperial geological institute for 17 years, and held many other appointments. In physics he was the discoverer of the interesting optical appearances which have been called after him "Haidinger's brushes." He died at Dornbach near Vienna on March 19, 1871.

Haidinger wrote many other works on mineralogy. Some of his papers will be found in the *Transactions* of the Royal Society of Edinburgh (vol. x.) and of the Wernerian Society (1822-23), *Edinburgh Phil. Journal*, *Brewster's Journal of Science*, and *Poggendorff's Annalen*.

HAIDRA, the ancient Ammadaera, a village on the frontier between Tunisia and Algeria, 20m. S.W. of Kalaa Djerda, the terminus of the railway from Tunis, and the loading point for the phosphates from the quarries of that name. The ruins of Ammadaera, where a colony of veterans was established at the end of the 1st century, are here. There is a fine triumphal arch, constructed in honour of Septimius Severus, another smaller arch and a mausoleum. There is an imposing citadel of the Byzantine period and two or three churches.

HAIDUK, a term probably derived from the Turkish *haidüd*, "marauder." The Haiduks of Serbia and Bulgaria were political outlaws and guerrilla champions of liberty; and the national movement in these countries was first led by bands of Haiduks.

In Hungary the name was applied to a class of mercenary foot-soldiers of Magyar stock. In 1605 these Haiduks were rewarded for their fidelity to the Protestant Party (see *HUNGARY: History*) with titles of nobility and territorial rights over a district situated on the left bank of the river Theiss, known thenceforward as the Haiduk region. This was enlarged in 1876 and converted into the county of Hajdú. In Austria-Hungary, Germany, Poland, Sweden and some other countries, *Haiduk* came to mean an attendant in court of law, or a male servant, dressed in Hungarian semi-military costume. It is also occasionally used as a synonym for "footman" or "lackey."

HAIFA, a city of Palestine at the foot of Mt. Carmel and south of the Bay of Acre, anc. Sycaminum. Haifa's place in history is but small. It was completely overshadowed by Acre. The modern town lies east of the old. With a roadstead free from reefs and a good anchorage for ships, it promises to become the chief seaport of Palestine. The building of a harbour with depth for the greatest vessels is mooted. It is the principal harbour of export for Hauran wheat and the products of Trans-Jordan, and has railway connection with both Damascus and Egypt. Even now (1928) it has a greater import trade than Jaffa. The population (mainly Arabic speaking) is about 35,000 and includes a flourishing German colony. Haifa has a large flour mill and cement and soap factories. Archaeologically it has little of interest to offer. (E. Ro.)

HAIG, DOUGLAS HAIG, 1ST EARL (1861-1928), British soldier, was born in Edinburgh, June 19, 1861, son of John Haig, of Cameronbridge, Fife. He was educated at Clifton and Brasenose college, Oxford, and in 1885 joined the 7th Hussars. He was promoted captain in 1891, afterwards passed through the staff college and was employed with the Egyptian army in 1898 during the Nile campaign, for which he was given a brevet majority. On the outbreak of hostilities in South Africa in 1899, he went out to Natal on the staff, and was present during the opening engagements near Ladysmith. He was afterwards chief staff officer of the cavalry division during Lord Roberts' victorious advance from Cape Colony through the Orange Free State into the Transvaal, and was promoted brevet lieutenant-colonel for his services.

In the later phases of the struggle he was in command of a column and later was controlling groups of columns; at the close of the war he was appointed A.D.C. to the King, promoted brevet-colonel, and given the C.B. Col. Haig subsequently commanded the 17th Lancers for a year, after which he went out to India as inspector-general of cavalry; this appointment he held until 1906, having been promoted major-general in 1905, in which year he married the Hon. Dorothy Vivian, daughter of the 3rd Lord Vivian. From 1906-09 he was a director in the War Office, and during this time he was intimately concerned in the development of the general staff and the improvements effected in the organization of the army, which were set on foot while Lord Haldane was secretary of State. In 1907 he published a volume of *Cavalry Studies*. His next appointment was that of chief of the general staff in India, which he held for three years, being promoted lieutenant-general in 1910. In 1912 he was brought home to take the command in Aldershot, and in 1913 he was made a K.C.B.

On the mobilization of the Expeditionary Force in 1914, Sir Douglas Haig took the field as commander of the I. Army Corps, which he led during the Mons, Marne and Aisne operations, and the first battle of Ypres; he was promoted full general in November for his services. On the division of the British Expeditionary Force into two armies at the beginning of 1915, he was placed at the head of the first. On the front of his army during 1915 there took place the battles of Neuve Chapelle, Festubert and Loos, and at the end of the year he succeeded Sir John French in the chief command. He had been made a G.C.B. in the autumn.

At this time the armies were passing through a period of transition. The regular army, with the exception of its cavalry, had almost ceased to exist and the first need was to weld its remnants, the new armies created by Lord Kitchener and the Territorial Army, into a whole capable of combined action both in attack and in defence. This involved the organization of an elaborate system of training for which it was necessary that a certain

number of divisions should be placed sufficiently far behind the line to allow them the ground and the opportunities for gaining experience.

This policy often brought Sir Douglas Haig into discussion both with the French generals and with the French statesmen, who were continually pressing him to take over a large extent of front. Sir Douglas Haig pointed out that it was not possible to compare a national army created during the course of the war with one which had been long established in time of peace, and that the Germans throughout the war maintained a greater density of men opposite the British lines than they did elsewhere. In the event, his policy was justified by the fact that in the latter half of 1918 the British army was, as a whole, at least as efficient as any which was then fighting in the war.

The campaigns and battles of the British army in France and Belgium are dealt with elsewhere and it is here only necessary to refer to the principles which guided Sir Douglas Haig in certain of the crises of the war. The first of these during his command arose out of the German attack on Verdun during the first half of 1916. On that occasion he assisted the French by relieving their troops in the front and by preparing for the battle of the Somme. While that battle disclosed defects both of preparation and of execution, its results convinced Sir Douglas Haig that it had caused such exhaustion of the German armies as should be exploited at the earliest possible moment. He therefore agreed with Joffre to renew the battle early in 1917.

But the battle of the Somme had caused grievous losses and the gains of ground as shown on the maps appeared trifling. Therefore, neither French nor British statesmen were prepared to agree to a policy which to their minds seemed likely to exhaust their resources before it caused the enemy to yield. The consequence of this was the replacement of Joffre by Nivelle and the assembly of an Allied Conference at Calais at the end of Feb. 1917, at which it was decided to give Nivelle the general direction of the British army, while he was at the same time to be in active command of the French army. This arrangement, militarily unsound, early produced friction. For Nivelle, who was ill-informed of events on the British front, issued to Haig instructions which were inappropriate both as to form and substance. These differences were adjusted at a further conference in London, but they created the impression that Haig was opposed to any form of unity of command, which was not true.

The direct result of the failure of Nivelle's campaign was a wave of depression which spread through the French armies and resulted in serious mutinies. Pétain, who had succeeded Nivelle, appealed to Haig to keep the Germans occupied while he was restoring the morale of the French troops. To this appeal Haig responded by opening in the summer of 1917 a campaign in Flanders, which began with Plumer's victory at Messines and was followed by the battle of Passchendaele. It was only with difficulty that Haig won the consent of the British Government to this campaign. By the middle of October of that year Pétain was able to tell Haig that the French army was sufficiently restored to be able to look after itself; and it might have been wiser to have stopped the battle of Passchendaele then, as no adequate return was gained for the exhaustion caused by the prolongation of the attack in execrable weather.

The crisis brought about by the success of the German-Austrian attack on the Italians at Caporetto following on the collapse of Russia, resulted in the creation in Nov. 1917 of the Supreme War Council, the first meeting of which was held at the end of the following January. This meeting had been preceded by a renewal of French demands for an extension of the British front, which Haig eventually met by agreeing to take over a portion of the line at and south of Peronne with his V. Army. At this meeting a difference of policy between Haig and his Government was disclosed. The commander-in-chief anticipated an early attack by the Germans and asked for reinforcements; the Prime Minister wished for an offensive campaign in Palestine, and won his way; and at this same conference, it was decided to create an Allied general reserve on the Western front under the control of the military representatives of the Supreme War Council with

Foch as chairman. During Feb. 1918 Haig became more than ever convinced that a great German attack on his front was imminent, in which he differed from the military representatives, who did not expect it before May. When the military representatives applied to him for divisions for the general reserve, he answered that in view of the lack of reinforcements, the extension of his front and the massing of German troops, he would be unable to furnish these divisions, and the formation of the general reserve broke down.

With what calm determination Haig met the great German offensive of the spring of 1918 is described elsewhere. In the most critical days of that offensive it was Haig's direct intervention with the British Government which brought Lord Milner to France, a visit which resulted eventually in giving Foch direct control of the Allied armies. With Foch Haig's relations were as harmonious as they had been with Joffre, and in the late summer of 1918 the British commander-in-chief reaped at last the reward of his patient policy. When in Aug. 1918 Rawlinson's IV. Army won the victory of Amiens, Foch desired that Rawlinson should follow up his success. Haig, convinced that this would result in another deadlock, and confident now in the superior morale and efficiency of his army, persuaded Foch to agree to an extension of the battle northwards, and so came about the breaking of the Hindenburg line which made it clear that victory could be won in 1918.

For his great services Sir Douglas Haig was raised to the peerage as Earl Haig and Baron Haig of Bemersyde and was given a grant of £100,000. The Order of Merit was also conferred upon him, and the ancestral home of the Haigs at Bemersyde was purchased by national subscription and presented to him. On returning home he was for a short time commander-in-chief in Great Britain, but when that position was abolished he refused other offers of employment and devoted himself wholly to the welfare of ex-service men. Before leaving France he had learned that many disabled and discharged soldiers were in distress, and he refused to accept any reward for himself until the Government had made better provision for the men who had served under him. Being satisfied that official provision must be supplemented by private benevolence he succeeded in uniting the various organizations of ex-service men into the British Legion (*q.v.*) of which he became president. By organizing the sale of poppies on November 11th, which became known as "Poppy Day," he created a large fund for the benefit of ex-service men. He also created and became president of the British Empire Services League, a union of the ex-service men's organizations of Great Britain and the dominions; he was also appointed chairman of the United Services fund, which, together with the British Legion fund, forms one of the largest benevolent organizations in Great Britain. He died on Jan. 29, 1928, and was buried at Dryburgh Abbey, Scotland, after national tributes to his memory had been paid at Westminster Abbey and St. Giles's cathedral, Edinburgh.

HAIK, a piece of cloth, usually of coarse hand-woven wool, worn by Arabs, Moors and other Mohammedan peoples (Arabic *hak*, to weave). It is generally 6 to 6½ yd. long, and about 2 yd. broad. It is either striped or plain, and is worn equally by both sexes, usually as an outer covering, but it is often the only garment of the poorer classes. Women arrange the "haik" to cover the head and, in the presence of men, hold it so as to conceal the face. A thin "haik" of silk, like a veil, is used by brides at their marriage.

HAIL is frozen raindrops, though hailstones are frequently much larger than any single raindrop which could be formed by any means. Rising convection currents, consequent on some local

instability of the atmosphere, result first in a heavy cloud—usually cumulo-nimbus in type—and then in raindrops which are carried upwards and freeze in the cooling air; during descent the hailstone receives another coating of water which may be frozen during a subsequent ascent in another part of the storm. This results in a concentric structure, but two or more stones may be cemented together until they assume large proportions and may reach 3 or 4 in. in diameter and a pound or more in weight; such masses of ice are capable of inflicting considerable damage. "Soft hail," Ger. *graupel*, Fr. *grésil*, consists of pellets of closely agglomerated ice crystals, and is a form of snow (*q.v.*). Soft hail breaks with a splash on impact with a hard substance, and therein differs from true hail; it also occurs with winter or spring storms as compared with the more usual summer thunderstorm with which hail is associated.

HAILES, DAVID DALRYMPLE, LORD (1726–1792), Scottish lawyer and historian, was born at Edinburgh, the son of Sir James Dalrymple, auditor-general of the exchequer of Scotland. He was educated at Eton, and studied law at Utrecht, being intended for the Scottish bar, to which he was admitted shortly after his return to Scotland in 1748. In 1766 he was elevated to the bench, when he assumed the title of Lord Hailes. Ten years later he was appointed a lord of justiciary. Lord Hailes's most important contribution to literature was the *Annals of Scotland* (2 vols. 1776–79).

HAILSHAM, DOUGLAS MCGAREL HOGG, 1ST VISCOUNT cr. 1929 (1872–), British lawyer and politician, was born on Feb. 28, 1872, the son of Quintin Hogg, founder of the Polytechnic, London. On leaving Eton Hogg spent eight years with his father's firm of West India merchants. After serving in the South African War (1899–1902), he was called to the bar (1902), and forthwith took a leading position as a junior. He became K.C. in 1917. His deadly power of cross-examination, easy mastery of facts and figures and persuasive speech made him formidable in every kind of case. In 1922, on entering parliament as Conservative member for Marylebone, he became attorney general in Bonar Law's government, receiving the usual knighthood given to a law officer. In opposition, or in office he showed himself a powerful debater; his vigorous speech on the Campbell prosecution (*see* ENGLISH HISTORY) had not a little to do with the defeat of MacDonald's Government. When the Conservatives returned to power in 1924, Hogg was re-appointed attorney general, with a seat in the cabinet, and in March 1928 he succeeded Lord Cave as lord chancellor.

HAILSHAM, a market-town of Sussex, England, 54 m. S.S.E. from London by the Southern Railway. Pop. (1921) 4,907. The church of St. Mary is Perpendicular. The Augustinian priory of Michelham, 2 m. W. by the Cuckmere river, is altered into a dwelling house, but retains a gate-house, crypt and other portions of Early English date. There was also a Premonstratensian house at Otham, 3 m. south. Hailsham has a considerable agricultural trade, and manufactures of bricks and pottery are carried on.

HAINAN (or Kiung-chow-fu), a large Chinese island separated from the Luichow peninsula of Kwangtung province by the shallow straits of Hainan, about 15 miles broad. It is the most southerly part of China (20° 8' to 17° 52' N. and 108° 32' to 111° 15' E.) and faces Tong-King (French Indo-China) across the gulf of that name. Its geology and build show it to belong physically to the mainland. The length of the island along its main N.E.–S.W. axis is 160 miles, its average width about 90 miles and its total area about 1,300 square miles. It is essentially rugged and mountainous with a central range (Wu-Chi-Shan) rising to a height of from 5–6,000 feet. On the north-west, north and eastern sides occur narrow coastal plains of which that facing the Strait of Hainan is the most important. Situated well to the south of the Tropic of Cancer and receiving a high rainfall, Hainan has a luxuriant tropical vegetation and the mountains are densely forested. The central mountain chain acts to some extent as a climatic divide, the coast plain to the north experiencing a relatively cool winter monsoon, while the southern districts are uniformly warm.

Hainan first came under Chinese control during the Early Han

Dynasty, Lu-Po-Teh, one of Wu-Ti's generals, occupying the island in 111 B.C. Its connection with the Empire was, however, rather nominal until the Yuan Dynasty (A.D. 1275–1368) when it was incorporated with the immediate mainland in a new satrapy Hai-peh Hai-nan Tao (Circuit north and south of the sea). Hence the popular designation of the island, meaning the district south of the sea. Since the administrative re-organisation of China under the Ming Dynasty (1368–1644) Hainan has been attached to the province of Kwangtung. Although there were a considerable number of Chinese immigrants, the island remained relatively undeveloped until comparatively recent times. It was used as a penal settlement and was a favourite place of escape for refugees. In 1858 by the Treaty of Tientsin, Kiung-chow the chief port was opened to foreign trade, but it was only about 1876 that full use was made of the permission. Since then piracy has been brought under control and a fairly active trade developed.

The population of Hainan is estimated at about 3,000,000. It is composite in character, reflecting the relationship of the island to China and Indo-China. (a) The aborigines, known as the Sheng-li (barbarians) seem to be closely related to the Laos and kindred peoples of Siam and Indo-China. They are mostly fishers and hunters, living in the interior valleys. (b) The Shu-li (civilized savages) are of mixed descent, but are largely descendants of refugees from the mainland, especially Hakka and Miaotze peoples. (c) The Chinese are the most recent immigrants but are now the most numerous element (about 2,000,000). They are found principally in the northern and north-western plains. Alike in the composition of its population and in the distribution of its constituent elements Hainan shows a rather striking correspondence to Formosa.

The economic resources of Hainan are considerable and are still in a relatively early stage of development.

The strictly agricultural areas are mainly confined to the marginal plains, particularly the northern. Here rice is the staple product and is exported to South China via Hongkong. Upon rice most of the island credit is based. A new and important development is the introduction of the plantation system for both rubber and sugar production. Hainan is one of the few districts in China where strictly equatorial products of the type cultivated in Malaya find suitable climatic conditions. The first rubber trees for the new plantations were introduced from Singapore in 1915 and the product is now marketed in that port, with which Hainan has an increasing trade. In marked contrast to the mainland of South China, cattle and horses are very numerous in Hainan, the breed of cattle being apparently a cross between the small yellow cow of China and the "zebu" of Indo-China. Animals and animal products, such as bullocks, pigs and hides are among the most important exports.

Apart from agriculture and animal rearing, Hainan has great potential resources in the dense forests of the highlands. It is known to be particularly rich in valuable tropical woods such as mahogany, rosewood, red and white cedar and hard woods suitable for sleepers. Various species of Indo-Malayan type are found in Hainan alone in all China. The coco-nut palm is cultivated with success and the highly prized nuts of the *areca catechu* (pinang) are reputed to be the best on the market. But the greater part of the forest wealth is at present quite inaccessible and will so remain until transport facilities are greatly increased.

The bulk of the trade of Hainan passes through Kiung-chow, the capital, situated in the Ta-Kiang basin in the centre of the Northern Plain and linked by a macadam road with its outport, an open roadstead, Hoi-hou. This lies on the important steamer route linking up Hongkong and the South China ports with those of the Gulf of Tong-King. Linkao and Tanchow further west are important centres for the sugar plantations. There are few towns of any size in the south, Yaichow in the centre of the chief district for cattle and hides being the most important.

HAINAUT, a province of Belgium, based on the ancient county of Hainaut. There are about 110,000 men and women employed in the coal and iron mines, and about 10,000 in iron and steel works. The chief towns are Mons, the capital, Charleroi, Tournai, Soignies and Thuin. The rivers are the Scheldt

and Sambre, and canals include one from Mons to Condé (joining the French Scheldt), one through Pommeroeul and one through Ath to Flanders, one (enlarged) from Charleroi to Brussels. There are 34 cantons and 344 communes. Area 930.405 acres or 1,453 sq.mls. Pop. (1925), 1,258,358 or 866 per square mile.

Under the successors of Clovis, Hainaut formed part, first of the kingdom of Metz, and then of that of Lotharingia. It afterwards became part of the duchy of Lorraine. The first to bear the title of count of Hainaut was Reginar "Long-Neck" (c. 875), who made himself master of the duchy of Lorraine and died in 916. His eldest son inherited Lower Lorraine, the younger, Reginar II., the countship of Hainaut, which remained in the male line of his descendants, all named Reginar, until the death of Reginar V. in 1036. His heiress, Richildis, married *en secondes nocces* Baldwin VI. of Flanders, and, by him, became the ancestress of the Baldwin (VI. of Hainaut) who in 1204 was raised by the Crusaders to the empire of Constantinople. The emperor Baldwin's elder daughter Jeanne brought the countship of Hainaut to her husbands Ferdinand of Portugal (d. 1233) and Thomas of Savoy (d. 1259). On her death in 1244, however, it passed to her sister Margaret, on whose death in 1279 it was inherited by her grandson, John of Avesnes, count of Holland (d. 1304). The countship of Hainaut remained united with that of Holland during the 14th and 15th centuries. It was under the counts William I. "the Good" (1304-37), whose daughter Philippa married Edward III. of England, and William II. (1337-45) that the communes of Hainaut attained great political importance. Margaret, who succeeded her brother William II. in 1345, by her marriage with the emperor Louis IV. brought Hainaut with the rest of her dominions to the house of Wittelsbach. Finally, early in the 15th century, the countess Jacqueline was dispossessed by Philip the Good of Burgundy, and Hainaut henceforward shared the fate of the rest of the Netherlands.

HAINBURG, a small town in Lower Austria, on the right bank of the Danube, a short distance above its confluence with the Morava. This is a significant site, commanding the passage of the Danube through the Porta Hungarica, between the Little Carpathians and the Leitha mountains, with a record of continuous settlement since pre-Roman time. Numerous Roman remains exist in and near the town and a Roman aqueduct still conveys its water supply, while history supplies ample evidence of the strategic value of the site in a record of struggle between the west and invaders from the east, Magyars and Turks, both of whom held the town at different times. Much of its old importance has been lost to Bratislava and to-day Hainburg is chiefly important for its large manufacture of tobacco and the attraction of its antiquities. Pop. (1923) 7,500.

HAINICHEN, a town of Germany, in the republic of Saxony, on the Kleine Striegis, 15 m. N.E. of Chemnitz, on the railway to Rosswein. Pop. (1925) 7,809. Its chief manufacture is flannels, baize, and similar fabrics. The special whiteness and excellence of the flannel made in Hainichen are due to the peculiar nature of the water used in the manufacture. There are also large dye-works and bleaching establishments.

HAINISCH, MICHAEL (1858-), Austrian statesman, was born on Aug. 15, 1858, at Aue, near Gloggnitz, Lower Austria, the son of a manufacturer, and of Marianne Hainisch, a pioneer of women's rights. After a short career in the Austrian public service, he devoted himself to the study of social and agricultural questions. As a practising farmer, he was a recognized authority on agriculture; while the interest which he took in the problems of the industrial labourer was shown by his joining with Engelbert Pernerstorfer to found the *Gesellschaft der Fabier* on the model of the British Fabian Society. Hainisch, who was particularly active in the cause of popular education, founded and endowed many hundreds of popular libraries. His works include: *Die Zukunft der deutschen Oesterreicher* (1892); *Voraussetzungen und Berechtigung des Sozialismus* (1919); *Die Landflucht* (Jena, 1923). Hainisch was elected first president of the Austrian republic in Dec. 1920 and re-elected unanimously for a further period of four years in Dec. 1924, leaving office in 1928.

HAI-PHONG, a seaport of Tongking, French Indo-China, on the Cua-Cam, a branch of the Song-koi (Red river) delta. Pop. 74,000. It is situated about 20 m. from the Gulf of Tongking and 58 m. E. by S. of Hanoi, with which it communicates by river and canal and by railway. It is the second commercial port of French Indo-China, is a naval station, and has government and private ship-building yards. The harbour is equipped with modern appliances and docks; there is a typhoon observatory at Phutien; it is accessible at all times to vessels drawing 19 to 20 ft., but is obstructed by a bar. It is the headquarters of the river steamboat service (*Messageries fluviales*) of Tongking, which plies as far as Lao-kay on the Song-koi, to the other chief towns of Tongking and northern Annam, and also to Hong-kong. There are cotton-spinning, soap, oil and cement factories.

HAIR, a word common to Teutonic languages; the general term for the characteristic outgrowth of the epidermis forming the coat of mammals. The word is also applied by analogy to the filamentous outgrowths from the body of insects, etc., plants, and metaphorically to anything of like appearance.

For anatomy, etc., of animal hair *see* SKIN and EXOSKELETON; FIBRES and allied articles; FUR; LEATHER.

Anthropology.—The human hair has an important place among the physical criteria of race. While its general structure and quantity vary comparatively little, its length in individuals and relatively in the two sexes, its form, its colour, its general consistency, and the appearance under the microscope of its transverse section show persistent differences, which give it its ethnological importance. The hair grows uniformly over the head in all races. The structure of the hair is threefold:—

(1) Short and crisp, generally termed "woolly"; elliptical or kidney-shaped in section, with no distinguishable medulla or pith. Its colour is almost always jet black, and it is characteristic of all the black races except the Australians and aborigines of India. This type of hair has two varieties. When the hairs are relatively long and the spiral of the curls large, the head has the appearance of being completely covered, as with some of the Melanesian races and most of the negroes. This type is called *ulotrichous* or "woolly." Among the Hottentots and Bushmen the hair grows in very short curls with narrow spirals and forms little tufts separated by spaces which appear bare. The head looks as if it were dotted over with pepper-seed, and thus this hair has gained the name of "peppercorn-growth." Most negroes have this type of hair in childhood and, even when fully grown, signs of it around the temples. The space between each tuft is not bald, as was at one time generally assumed.

(2) Straight, lank, long and coarse, round or nearly so in section, with the medulla or pith easily distinguishable, and almost without exception black. This is the hair of the yellow races, the Chinese, Mongols and Indians of the Americas. This is designated *leiotrichous* or *lissotrichous*.

(3) Wavy and curly, or smooth and silky, oval in section, with medullary tube but no pith. This is the hair of Europeans, and is mainly fair, with black, brown, red, or towy varieties. This is termed *cymotrichous*.

There is a fourth type of hair describable as "frizzy." It is easily distinguishable from the Asiatic and European types, but not from the negroid wool. It is always thick and black, and is characteristic of the Australians, Nubians, and certain of the Mulattos. Generally hair curls in proportion to its flatness. The rounder it is the stiffer and lankier. These extremes are respectively represented by the Papuans and the Japanese. The woolly type is found to be the most persistent.

Wavy types of hair vary most in colour: almost the deepest hue of black being found side by side with the most flaxen and towy. Colour varies less in the lank type and scarcely at all in the woolly. The only important exception to the uniform blackness of the negroid wool is to be found among the African pygmies, whose hair is described as "of a dark, rusty brown hue." Fair hair in all its shades is frequent among the population of northern Europe, but much rarer in the south.

The percentage of brown hair is 75% among Spaniards, 39 among French, and 16 only in Scandinavia. Among the straight-

haired races fair hair is far rarer; it is, however, found among the western Finns. Among those races with frizzy hair red is almost as common as among those with wavy hair. Red hair,

The wavy-haired populations hold also an intermediate position, but somewhat inclined to hairiness. Among negroes especially no rule can be formulated. Bare types such as the Bushmen and western negroes are found contiguous to hairy types such as the inhabitants of Ashanti. Neither is there any rule as to baldness. The *lanugo* or downy hairs, with which the human foetus is covered for some time before birth and which is mostly shed in the womb, and the minute hairs which cover nearly every part of the adult human body, may be regarded as rudimentary remains of a complete hairy covering in the ancestors of mankind. Perhaps the primary divisions of mankind were distinguished by hair the same in texture and colour as that which characterizes to-day the great ethnical groups. The wavy type bridges the gulf between the lank and woolly types. No test has proved, on repeated examination, to be a safer one of racial purity than the hair, and Pruner-Bey goes so far as to suggest that "a single hair presenting the average form characteristic of the race might serve to define it." At any rate a hair of an individual bears the stamp of his origin.

See Dr. Pruner-Bey in *Mémoires de la société d'anthropologie*, ii.; P. A. Brown, *Classification of Mankind by the Hair*; P. Topinard, *L'Homme dans la nature*, chap. vi. (1891); A. C. Haddon, *Races of Man* (1924). (X.)

IN MAMMALS

Characteristically, Mammalian hairs are developed in relatively deep pits in the skin, the hair-follicles, which extend downwards into the thickness of the corium, or even into the subcutaneous tissue. In man the hair-rudiments begin to appear about the third or fourth month of foetal life as small solid downgrowths from the Malpighian layer of the epidermis, their growth being completed about the fifth or sixth month, when they constitute the very delicate hairy covering, the *lanugo*, which is entirely shed before birth. The hairs constituting this are fine, slender, faintly or not pigmented, with large cortical scales and no medulla, and possess some of the characteristics of wool. At birth the hairs of the eyelashes, eyebrows and scalp, though still soft and more or less retaining the characteristics of *lanugo*, already show a much more vigorous growth and may be pigmented. During the first few months of infancy this growth is shed, being replaced by the typical coarser hair of the eyebrows and head, while over the rest of the body grows the fine, short, generally unpigmented down-hair or *vellus*. Finally, at and following puberty, coarse, longer and more heavily pigmented hair (terminal hair) is developed in armpits (axilla), pubes, certain areas of the trunk and limbs, and in males on the upper lip and chin.

The amount of terminal hair varies according to race, sex and even individual, though generally more abundant in males, the greater part of the body in adult females still being covered by vellus. While there are little or no sexual differences distinguishing the auxiliary hairs, slight differences are observed in the pubic hairs, which appear rather longer and more abundant in men, and relatively coarser in women. One characteristic human trait is that most of the body hairs never develop beyond more or less rudimentary vellus, whereas in other mammals the coarser forms predominate, and, in addition, tactile hairs (sensory vibrissae) are present. The total area of really hairless skin in man is relatively small, being confined to the palms of the hands, soles of the feet, under-surface of the fingers and toes, the margin of the lips, areolae of the nipples, umbilicus and immediate vicinity of the urogenital and anal openings.

The Hair-follicle.—This structure, which is essentially a recess of the skin, is composed of two tissue elements, one, of epithelial origin, closely invests the hair-root, while the second is connective tissue. A cross-section of a hair-follicle shows that the epithelial layer consists of an outer layer of polyhedral cells forming the outer root-sheath, and an inner, horny stratum, the inner root-sheath, composed of three layers, known respectively as Henle's layer (the outermost) of horny, fibrous, oblong cells; Huxley's layer, consisting of polyhedral, nucleated cells containing pigment granules; and the cuticle of the root-sheath, composed of a layer of downwardly imbricated scales that fit over the upwardly imbricate scales of the hair proper. The connective tissue

however, is an individual anomaly associated ordinarily with freckles. There are no red-haired races.

A certain correlation appears to exist between the nature of hair and its absolute or relative length in the two sexes. Thus straight hair is the longest (Chinese, Red Indians), while woolly is shortest. Wavy hair holds an intermediate position. In the two extremes the difference of length in man and woman is scarcely noticeable. In some lank-haired races, men's tresses are as long as women's, as in the Chinese pigtail, and the hair of Redskins which grows to the length sometimes upwards of 9 ft. In the frizzy-haired peoples, men and women have equally short growths. It is only in the wavy, and now and again in the frizzy types, that the difference in the sexes is marked. The growth of hair on the body corresponds in general with that on the head. The hairiest races are the Australians and Tasmanians. The least hairy peoples are the yellow races, the men often scarcely having rudimentary beards, e.g. Indians of America and the Mongols. Negroid peoples may be said to be intermediate but usually incline to hairlessness.

element consists internally of a vascular layer separated from the root-sheath by a basement-membrane, the hyaline layer of the follicle, and externally has a more open texture corresponding to the deeper part of the cutis containing the larger branches of the arteries and veins. A small muscle, the *arrector pili*, is attached to each hair-follicle. It passes from the superficial part of the corium, on the side to which the hair slopes, obliquely downwards, to be attached near the bottom of the follicle to a projection formed by localized hypertrophy of the outer root-sheath. If this muscle is contracted, the hair becomes more erect, and the follicle is dragged upwards to cause a prominence on the general surface of the skin, producing that temporarily roughened condition popularly called "goose-skin."

Process of Growth.—The hair grows upwards from the bottom of the follicle by multiplication of the soft cells which cover the papilla and these become elongated and pigmented to form the fibrous substance of the hair-shaft, and are otherwise modified to produce the central medulla and cuticle of the hair. The hair-shaft is chiefly composed of a pigmented, horny, fibrous material, which consists, really, of long, tapering, fibrillated cells that have coalesced. Externally this fibrous substance is covered by a delicate layer of imbricated scales forming the cuticle. In many hairs, the centre of the shaft is occupied by an axial substance, the medulla, formed of angular cells containing granules of elæidin, and frequently in addition, minute air-bubbles which give the cells a dark appearance. The medullary cells tend to be grouped along the central axis of the hair as a core; continuous or interrupted in single, double or multiple columns. The variations in the medulla may be summarized as: (a) the continuous type, which may be homogeneous, as in the chimpanzee, or nodose as in the gelada baboon; (b) discontinuous medullas, which in simple forms may be ovate, elongated, or flattened (in *Hylobates* it is discontinuous and elongated); (c) a fragmental type, as in *Semnopithecus*.

Cuticular Scales.—The delicate cuticular scales are most varied in shape and size, and constitute the most important microscopical structure of the mammalian hair, for they possess definite and constant specific characters. The dominant form is an imbricate scale, like a tile of irregular shape, having its edges rounded, minutely notched or flattened. There are many varieties of the imbricate scale, each typical of its species; thus in man, chimpanzee, gorilla and orang-utan, the hairs have imbricate scales which are, however, quite distinctive in size, shape and structure of the edge (slightly oval in chimpanzee, slightly ovate and crenulate in man and gorilla, with strongly marked [crenulate] edges in orang). The second type of cuticular scale is the coronal in which each individual cuticular cell completely encircles the hair-shaft, and may have a simple, serrated or dentated edge. While the imbricate scale is typical of the higher Primates, the coronal scale in its simpler form is present in the Lemnidae and *Tarsius*; becoming in the Insectivora more specialized, with serrate or dentate edges.

In some Indian bats the cuticular scales are developed as leaflet-like processes arranged in whorls at regular intervals along the hair-shaft. In many deer (*Cervus*), the cortical substance is nearly indistinguishable, almost the entire hair appearing to be composed of thin-walled polygonal cells. In the peccary the cortical envelope sends inwards radial prolongations, the interspaces of which are occupied by medullary substance; and this, on a larger scale, is the structure of the porcupine's "quills." One of the most remarkable mammalian hairs is that of the Australian *Ornithorhynchus*, in which the lower portion of the shaft is slender and wool-like, while the free-end terminates as a flattened, spear-shaped, pigmented hair with broad imbricated scales. In the three-toed sloth (*Bradypus tridactylus*), a microscopic alga grows between the cuticular scales of the hairs, and would appear to be symbiotic, inasmuch that its presence, giving a curious greenish-gray hue to the coat of the sloth, helps to disguise the animal among the trees, giving it when viewed from the ground almost the appearance of a mass of moss.

Tactile Hairs.—These occur in all mammals except man, and are large, stiff hairs of pre-eminently sensory character, having

high specialized follicles, the root being embedded in a mass of true erectile tissue (*corpus cavernosum, corpus spongiosum pili*), and having a rich sensory nerve supply, presumably controlled by the sympathetic nervous system. These specialized hairs are few in number, their distribution being chiefly confined to the lips, cheeks and supra-orbital regions, occasionally occurring elsewhere.

CARE OF THE HAIR

The beauty of the hair is dependent largely upon its health. A clean scalp, nourished by a strong circulation of pure rich blood, is essential. Any disease or subnormal physical condition which pollutes the blood stream or depletes its nutrient properties is reflected in the condition of the hair. People suffering from poor circulation, or anaemia, for instance, generally have weak or lusterless hair. Obviously, hygienic living, outdoor exercise, correct diet, mental happiness, everything that contributes to physical well-being will contribute to the health and natural beauty of the hair.

Massaging the Scalp.—At least once a day, devote several minutes to the massage of the scalp. Plant the thumbs back of the ears and spread the fingers over the fore part of the head. Then rotate the scalp under the finger tips, being sure that it is the scalp that moves and not the fingers. Move the hands about and repeat the rotary movements until every area of the scalp has been stimulated. Then press the palms of the hands firmly against the scalp, and lift and massage the scalp with deep pressure. A loose elastic scalp ensures freedom of circulation through the scalp tissues and about the hair roots. A tight scalp breeds thin weak hair. Pinching the scalp and pulling the hair (not in jerks, but with steady lifting pulls) are other means of loosening the scalp, increasing its suppleness and stimulating the flow of blood in its tissues.

Tonics, lotions, ointments or pomades are applied to the scalp by means of these massage movements. These preparations are formulated to correct or ameliorate various scalp conditions, excessive oiliness and excessive dryness being the commonest. Normally, the oil glands, which are attached to the roots of the hairs, secrete a natural lubricant in sufficient quantity to keep the surface of the scalp soft and to keep the hair supple and lustrous. Ill health, or local infection, may disturb the functioning of these oil glands, and excessive oiliness, or a lack of natural oil, may result. For excessive oiliness, astringent lotions and tonics are used, and these should be applied directly to the scalp (with a medicine dropper, or a swab of absorbent cotton) and massaged into the scalp. For dry hair, ointments and pomades are used, which serve to supply the lack of natural lubrication in the scalp.

The hair should be brushed conscientiously for several minutes morning and night, the brush having firm and resilient bristles long enough to penetrate to the scalp. Always brush under the hair and upward, lifting the hair and the scalp to exercise it. Brush the full length of the hair to clean it and to distribute the natural oil down the length of the hair. This helps to keep the hair supple and lustrous. Wipe the brush on a clean towel several times during the brushing, to remove dust and lint. Brushing stimulates circulation in the scalp, and this daily brushing should leave the scalp glowing and pink, but not sore or irritated. Wash combs and brushes frequently.

Shampooing.—The hair should be shampooed as frequently as is necessary to keep the scalp clean and the hair clean and glossy. In smoky or dusty cities, of course, this is oftener than in the country. Oily hair needs washing oftener than dry hair. In any case, however, the hair should be washed at least every fortnight. Absolute cleanliness is the best means of protecting and preserving the health of the hair, of preventing dandruff or other infection, and of correcting any unhealthy scalp conditions.

Arrangement of Hair.—The modern freedom of taste and

interest in the development of individual personality have given rise to an endless variety of coiffures for women. The present-day woman is encouraged by everyone to wear her hair as it becomes her, or as it expresses her individuality. The hair may be worn short or long, waved or straight, flat or fluffed. More and more, women are learning the importance of line and proportion, and the coiffure is studied as a part of the ensemble effect, its relation to the shape of the head and as a frame for the face.

Hair Cutting.—Hair cutting involves no little skill, and the work of an amateur is apparent at once. Hair cutting is taught by the method of observation and practice in barbers' schools and in schools of beauty culture. The expert learns to lift the hair from the head and graduate the cutting of each lock, so as to avoid stubby ends and procure a smooth rounded appearance that follows the contour of the head. Too heavy hair is thinned at the roots to make it lie flat to the head. The hairdresser who has contributed most to artistic hair cutting for women, Antoine of Paris, was formerly a sculptor, and he has given the modern woman's head that sculptured look which makes her classically beautiful. (D. Co.)

HAIR-TAIL (*Trichiurus*), a marine fish with a long band-like body terminating in a thread-like tail, and with strong prominent teeth in both jaws. Several species are known.

HAITI (HAÏTI, HAYTI, SAN DOMINGO, SANTO DOMINGO or HISPANIOLA), an island of the Greater Antilles. (See WEST INDIES.) It is separated from Cuba by the Windward passage; the Mona passage separates it from Porto Rico; to the north is the Atlantic ocean, south, the Caribbean sea. Haiti is wholly in the tropics 17° 39' and 20° N. and 68° 20' and 74° 30' W., area 28,242 square miles. High mountains descend abruptly to the sea along much of the shore. About two-thirds of Haiti is rugged mountain, with small alluvial plains, extensive plateaux and great valleys on the remainder. The western third is the Republic of Haiti, with a negro population of 2,000,000 speaking a French *patois*. The rest is the Dominican Republic (*q.v.*). The boundary, which is disputed, runs north-south at right angles to the major surface features.

Geology and Physiography.—Haiti has its major geographic features in arcs. These extend north-west-south-east and determine the major mountain ranges. The great mountain ranges are anticlinal arches; between them lie deep synclinal troughs, forming river valleys and interior plateaux and sometimes outlining the coastal alluvial plains. Normal faulting made the broad Trois Rivières structural valley and many minor land forms.

A complex group of schists, serpentines, extrusive and intrusive igneous rocks, tuffs and altered limestones, shales and conglomerates form the basal complex and are exposed along the axis of the Cordillera Central and the Haitien Massif du Nord. These are primarily Cretaceous. Most of the Samana peninsula and separated areas in the south-western peninsula also have Cretaceous surface rock. Probable Palaeozoic rock is in the schistose limestones of Tortuga island, the south slopes of the Samana peninsula, certain highly metamorphosed rocks of the Cordillera Central and the foot of the Leogane and North plains. The most widespread surface rocks are Eocene limestones, principally in the western third of Haiti. Late Tertiary and Quaternary sediments are common. Sedimentary rocks, largely limestones, ranging from probable Palaeozoic to recent, are about two-thirds of the surface rock. Solution in the more massive limestones made characteristic land and drainage features. There are many recent complex coastal delta plains.

The tectonic event most affecting present surface features was folding and faulting at the end of Miocene and in Pliocene times, when the Cul de Sac-Enriquillo, Artibonite, San Juan and Cibao valleys and the Central plain depression and chief mountain ranges were formed or modified. Folding and mountain-making processes are evidenced by recent earthquakes, chiefly in the densely populated unconsolidated alluvial plains of the north-west peninsula.

The Cordillera Septentrional (Monti Cristi) runs parallel to the north coast of the Dominican Republic from near Monti Cristi to the Yuna. The western part is low, dry and sparsely populated. North of Santiago, are elevations of probably over 4,000 feet.

Here there is rainfall and production. The low mountains of the Samana peninsula are separated from the Cordillera Septentrional by a low, narrow, swampy plain. Much coffee grows on the south slopes of the peninsula, with large forests on crests and north slopes. South and parallel to these mountains is the Cibao valley, which is continuous with the North plain. In the eastern half of the valley, drained by the Yuna and tributaries, cacao, bananas and tobacco are grown and verdant savannas support many cattle. Here are Santiago and other large towns and the Santiago-Samana railroad. The western part is arid, covered with cactus and mesquite. The Río Yaqui del Norte traverses it and affords almost the only water for domestic use. The population is sparse, except on the Yaqui delta, where sugar-cane is grown by irrigation. The North plain borders the Atlantic. Near the frontier it is dry and largely covered with long grass savanna. Westward, near Cap Haitien, there is abundant rain and much sugar-cane is grown. To the south, the Cordillera Central and Massif du Nord form the backbone of the island. This is composed of many ranges and isolated mountains. Metamorphic, igneous and sedimentary rocks are exposed. The north and east slopes are humid, with verdant forests. Some mahogany and other commercial woods are exploited. Coffee, cacao and native gardens claim much land. Crests of limestone or porous basalt support short-leaf yellow pines and tall grass. The lower lee slopes are dry and unproductive. Throughout the Montagnes du Nord coffee grows virtually wild. West of the Trois Rivières the Montagnes du Nordouest form a genetic continuation and reach nearly to the Mole St. Nicolas. Loma Tina, 10,300 ft. (South central Cordillera Central), is the highest elevation in the West Indies.

Near the Ennery-Gonaïves road the Mornes des Cahos swing south-eastward to the Dominican frontier near Las Cahabas. This range is less high and complex than that to the north; limestone is the chief surface rock. There is much coffee west of the Artibonite river. To the east the range narrows and the low crest is rolling upland. Between the Mornes des Cahos and the Massif du Nord is the 1,000 ft. inter-montaine Central plain plateau. The north-western two-thirds is a tall grass savanna. It was once an important cattle area but political conditions have ruined that industry. South-east of Hinche, the chief town, the plateau is intricately dissected and the well-watered river valleys support dense agricultural populations.

The Central plain merges into the fertile and well-watered San Juan valley at the frontier. South of the Morne des Cahos is the Artibonite valley. At its west or sea end is the Gulf of Gonaïves and a great delta plain. This, although but partly developed, contains about 100,000 ac. (pop. 200,000) and offers most attractive irrigation possibilities. Rainfall, which is but 20.6 in. at Gonaïves, increases eastward to 90 in. about Mirebalais. The Artibonite fluctuates greatly with very large floods. It is navigated by rafts and canoes to Mirebalais and large quantities of logwood reach the sea by it. South of the Artibonite, the Chaîne des Mateaux (Sierra de Neiba, east of the frontier) swings south-eastward from near St. Marc to Ocoa bay. St. Marc coffee comes from the western section, while in the central part is much short-leaf yellow pine. Next southward is the Cul de Sac-Hoya Enriquillo. This remarkable trough is filled with alluvium and contains the two great lakes, known as Étang Saumâtre (c. 69.5 sq.m.) and Lago Enriquillo. Neither has outlets and their waters are saltier than sea water. The Lago Enriquillo is drying up; its surface is 145 ft. below sea-level. The Cul de Sac is the most densely populated and productive part of the Republic of Haiti.

Much sugar is produced on irrigated land. The capital, Port-au-Prince, is on this plain and owes much of its importance to it. The Dominican portion is not so densely populated or productive, owing largely to aridity. South of the Cordillera Central are two plains, Azua and Seibo, separated by a branch of the Cordillera Central. The western or Azua plain is dry and sparsely populated, but the Seibo has water and a large sugar industry. The mountain range which forms the south-western peninsula continues as the Sierra de Bahoruco, the western part is the Massif de la Hotte (Mont la Hotte, 6,560 ft.). Here coffee is an important crop and, south of Jeremie, cacao. Inland are virgin forests of mahogany

and other commercial trees. The fertile and well-watered plain Aux Cayes is south of the mountains. The central portion of the range is the Massif de la Selle (Mont la Selle, 9,186 ft.). Coffee is important and there is much pine and *lignum vitae*.

Cliffed coast-lines are the usual types. Where intermittent emergence has taken place there are stair-like sea terraces; at least 20 are on the south shore of the north-west peninsula. Elsewhere the sea has cut cliffs into the mountains, or the cliffs are broken by crescent-shaped sand beaches or deep indentures. The best harbours are on this latter type of coast; but *hinterlands* are generally poor. The most important ports are near the population and production centres on the alluvial plains. Here shallows continue some distance from shore and there are many reefs and mangrove barriers.

Climate.—There is a wide climatic range due to diversity of rainfall and the north-east trades. Mole St. Nicholas is in the lee of mountains and has an average annual rainfall of but 19.25 in., while Mirebalais, at the juncture of mountain valleys, has 90.7 inches. No point has much over 100 in. and large areas are sterile without irrigation. Temperatures vary chiefly with elevation. There are everywhere well-defined spring and autumn rainy seasons, and planting conforms to these. Otherwise, rain varies much with place and year. Port-au-Prince (alt. 121 ft.) and Furcy (5,050 ft.) have mean annual temperatures, respectively, of 80.96° and 66.0° F. There is a fall in temperature of 1° F to every 275 ft. elevation. Thus, even at the highest elevations, temperatures are too high for frost, snow or ice. Daily temperature range averages about 18° F everywhere, while the monthly range is about 9° F. The heat is not uncomfortable except on sheltered lowlands. Hurricanes are sometimes destructive but are less frequent than in the south-eastern islands.

Fauna and Flora.—There is great wealth of species and numbers among insects, while larger animal groups are lacking in both respects. The most prevalent and harmful insects are mosquitoes. Cockroaches and ants are destructive. Sand flies and chiggers abound in some areas. Ticks and blow-flies are a detriment to stock-raising. Scorpions, centipedes and some large spiders are poisonous, but their bites are not usually fatal. Butterflies are surprisingly numerous in late summer. There are few snakes, and none of them poisonous. A number of water-fowl, such as wild ducks, geese and pelicans, occur. Among the shore birds are snipe, flamingos and egrets. Doves and pigeons, a kind of partridge and feral guinea fowl are the chief game birds, and there are white owls, large hawks, woodpeckers and kingfishers. Many fishes, oysters, lobsters and crabs are eaten.

Mesophytic vegetation is largely confined to rainy slopes and stream banks. It includes royal palms, silk cotton trees, Haitian oaks, logwood or campeche, flamboyant, West Indian cedars, short leaf yellow pines, calabash, mahogany, gri-gri, *lignum vitae*, satinwood, rosewood, Brazil wood, fustic and sassafras. There are also avocados, sour and sweet sops, custard and star apples and *capote*. Oranges, limes, grapefruit, guava, mulberry, mango and breadfruit, although exotic, grow wild, as do coffee, cacao and coco-nut trees. Guinea grass grows in cleared forests. Bamboo, tree ferns and begonias are usually found in moist slope forests. Xerophytic types are on lower leeward slopes and dry plains. Tall and short grass savannas occupy wide areas. Cactus is widespread; several very high species grow on dry plains. Smaller varieties are *Opuntia picardae*, caribea and tuna. *Lotia candelabra*, *Cereus heystrek* and various agaves and palmettos occur. The *bayahonde* (*Prosopis juliflora*), cacti and acacia (*Acacia lutea*) form thorn forests on drier plains. Among halophytic types the black, red and grey mangroves are frequent on the shores. Cacti and dwarfed thorn trees are on high alkaline coastal soils. The forests were largely depleted in colonial times and after; commercial stands are mostly limited. Logwood and *lignum vitae* are for export.

Cotton, maize, tobacco, cocoa, manioc, malanga, banana, plantain, pineapple and yams are indigenous. Sugar-cane, coffee, rice, guinea grass, citrus fruits, fig, breadfruit and others are acclimated.

The Republic.—This occupies the western third (10,200 sq.m. including Gonaïve, Tortuga and the Cayemites; pop. 2,000,000).

The density of population in parts of the well watered plains is over 500 to the square mile; large sections elsewhere are virtually unoccupied. At least 90% of the population is pure negro and the remainder mulatto. Port-au-Prince is the capital (pop. 125,000). Cap Haitien, on the north coast, was the capital of the French colony and is now the second city (pop. 25,000). Others are Les Cayes (15,000), Gonaïves (12,000), St. Marc (10,000), Jacmel (10,000), Jeremie (8,000), and Port de Paix (5,000). Although small and backward, Haiti was the earliest State governed constitutionally by negroes.

History.—Haiti was discovered by Columbus, who landed at Mole St. Nicolas on Dec. 6, 1492. The inhabitants—Indians (1,000,000 to 3,000,000)—were an agricultural and fishing people who were then suffering from Carib raids. Columbus called the island La Española (soon corrupted into Hispaniola) and settlers stayed at La Navidad (Petite Anse), near Cap Haitien. Almost all the Indians were shortly slaughtered or worked to death in quest of gold. By 1512 negro slaves were imported. Sugar-cane was introduced in 1506. The Spanish soon went to the mainland, leaving Haiti deserted. About 1630 French and English buccaneers settled on Tortuga. They soon came to the mainland and (Treaty of Ryswick, 1697) the part they occupied was ceded to France. The French colony of Saint Dominique, based upon slavery and irrigation, was one of the most prosperous of all tropical enterprises. Sugar, cotton, coffee and indigo were staples. Many free *mulattos* became property owners. Political rights were granted them in 1789. The whites protested and fierce struggles ensued. Then England, solicited by the French planters, intervened, as did the Spanish. Toussaint L'Overture, the most notable Haitian soldier and statesman, sided with France and drove out both alien groups, becoming governor for France; but Napoleon I. soon substituted Gen. Leclerc. A long struggle ensued in which the negroes, aided by fever and heat, successfully competed with the French. Finally, Toussaint was captured by ruse and died in prison in France. Jean Jacques Dessalines became leader and defeated Richambeau, Leclerc's successor, in Nov. 1803.

On Jan. 1, 1804, independence was declared and the Indian name Haiti taken for the State. Dessalines, made governor for life, began by massacring all whites. He soon crowned himself emperor, but in 1806 was assassinated because of his tyranny. Henri Christophe then ruled in the north as King Henry I., and built the famous citadel La Ferrière which stands south of Cap Haitien. Alexandre Sabes Pétion, a most able mulatto, ruled the south. War raged until Gen. Jean Pierre Boyer got control of the south (1818) and until the death of Christophe (1820). In 1821,

CITADEL OF CHRISTOPHE, NEGRO KING OF HAITI, NEAR CAP HAITIEN. The citadel is a huge mass of masonry perched on top of the highest and most inaccessible peak in the district. Christophe reigned from 1811 to 1820.

the Spanish portion of the island proclaimed its independence. Boyer invaded it and in 1822 ruled the whole island. A revolution drove him out in 1843; the Dominican Republic (*q.v.*) was founded and there have since been two nations on Haiti.

There was almost constant revolution until American intervention (1915). Irrigation projects fell into decay; production and foreign trade dwindled. Political mismanagement increased the public debt. The courts were corrupt. Education, except that carried on by French priests, practically ceased. There was little protection of property and no industrial encouragement.

Poverty and disease added to the general distress. The interior swarmed with bandits. In Dec. 1913, Oreste Zamor and Davilmar Theodore overthrew Michel Crete; Zamor became president on Feb. 8, 1914 and was displaced by Theodore on Nov. 7, 1914.

Intervention by the United States.—Vilbrun Guillaume Sam assumed government on March 4, 1915, holding it against violent opposition until forced to seek refuge at the French legation on July 26, 1915. About 200 political prisoners were bayoneted in the gaol at Port-au-Prince and Sam was dragged from the legation and massacred by the mob. Two hours later U.S. marines landed at Port-au-Prince, assumed occupation, disarmed the natives and restored order. U.S. naval officers took over most administrative functions but the Haitian Government remained. On Aug. 12, 1915, Sudre Dartiguenave was chosen president by the Haitian Congress. On Feb. 28, 1916, the U.S. Senate unanimously gave its advice and consent to a treaty (Nov. 11, 1916) with Haiti. It was made for ten years and provided that "the Government of the United States will, by its good offices, aid the Haitian Government in the proper and efficient development of its agricultural, mineral and commercial resources and in the establishment of the finances of Haiti on a firm and solid basis," and stated how. A serious outbreak against American authority took place in July 1918, under the leadership of Charlemagne Perlate, an ex-bandit. The *gendarmérie* being inadequate, the marines were compelled to act. In May 1920 peace was restored. Reconstruction has since gone forward unobstructed except by certain Haitian leaders and some American public sentiment. Louis Borno became president on May 15, 1922, and was re-elected on April 12, 1926. The original treaty was extended in 1925 for ten years.

The chief American official, Brig.-gen. John H. Russell, is the high commissioner, and has the rank of ambassador. Under him are five departments: financial adviser-general receiver of customs, public works, sanitary service, agricultural service and *gendarmérie*. These reduced the public debt (about \$31,000,000 on Sept. 1, 1915) to less than \$20,000,000 in 1927. Tax and customs laws were revised and favourably affected foreign trade. The monetary unit (*gourds*), was stabilized on May 2, 1919, at U.S. \$0.20. Bridges, trails, harbours, public buildings, irrigation and the telephone, telegraph and lighthouse services and sanitation have been improved. Agricultural information has been spread and such crops as sisal introduced.

The chiefs of departments are Americans, advised by American experts, and each co-operates with the corresponding number of the Haitian cabinet.

The treaty did not provide for education, and but two schools are maintained besides the Government ones, which are very poor. The church schools specialize in religious education. Some of the small upper class are educated in France, but strong social stratification prohibits dissemination. The Haitian courts are corrupt and the uniform enforcement of laws is impossible. The per caput wealth amounts to but \$60 and law and politics keep out foreign capital. Slavery under the French was of the worst type. After the revolution there was nominal democracy, but really absolute, though unstable, despotism. Poverty and ignorance continue, and labour is confused with slavery. Irrigation is being revived, but the area suitable is very limited. The forests have been largely depleted and minerals are rare.

Production and Trade.—Most production is through small farmers and is consumed locally. Exports, excepting sugar, are wild or semi-wild products gathered by peasants in off seasons. Coffee is the most important export (almost 75% of the total), and thus Haiti has the disadvantages of a one-crop country; national and coffee trade prosperity are almost one. The average values of the chief exports for 1916-17 to 1926-27 were: coffee, \$10,801,933; cotton, \$1,477,245; logwood, \$813,564; sugar, \$450,002; cacao, \$391,192. All exports amounted to \$14,916,413. Hides and skins, cotton-seeds, honey and bees-wax, *lignum vitae* and turtle shells are exported and follow cacao in the order named. France, in this period, used 48.99% of the exports, largely coffee, and the United States 29.4%, including logwood, sugar and cotton. Imports (average for above period, \$15,573,150) somewhat exceed exports. This is partly offset by money brought by labourers from

Cuba and by American marines. Food-stuffs, especially wheat flour, are 37% of the imports; textiles, largely cotton cloth, 28%. Others are building materials, mineral oils, soap and liquors. Tobacco importation has recently been replaced by local production. The United States sends 82% of imports, Great Britain 6%, and France 5%. Port-au-Prince handles 21% of exports and 54% of imports. Cap Haitien, Jacmel, Les Cayes, Petit Goave, Gonaïves and St. Marc each handle 5%-10% of the foreign trade. The total national revenue, 1926-27, was \$7,772,306 (72% from customs). The coffee export tax ranks first, but its importance has recently declined due to a better balanced schedule. Transportation is inadequate for bringing products to port. However, nearly 1,000 m. of road, open for motors at least part of the year, have been opened. These are bound by an intricate network of trails to the remotest districts. There are only 65 m. of national railroad. This unit connects Port-au-Prince and St. Marc. The Gonaïves-Ennery division equipment is being partly transferred to the St. Marc-Petite Rivière, now under construction. The Haitian-American Sugar Company also uses some 55 m. of track (Cul de Sac and Leogane plains). Its gauge is not that of the national line. The National Bank of Haiti, a subsidiary of the National City Bank of New York, and the Royal Bank of Canada, conduct banking.

HĀJJĪ (Arabic, "pilgrim"), one who makes the *hajj* or greater pilgrimage to Mecca, from the 8th to the 10th of the twelfth month of the Muhammadan year. The lesser pilgrimage, called *umrah*, may be made to the mosque at Mecca at any time other than that of the *hajj* proper, and is also a meritorious act. The word *hajj* is sometimes loosely used of any Muhammadan pilgrimage to a sacred place or shrine, and is also applied to the pilgrimages of Christians of the East to the Holy Sepulchre at Jerusalem (*see* MECCA; ISLAM).

HĀJJĪ KHALĪFA (Muṣṭafā ibn 'Abdallāh Kātib Chelebi Hājji Khalifa) (c. 1599-1658), Arabic and Turkish author, was born at Constantinople. He became secretary to the commissariat department of the Turkish army in Anatolia, was with the army in Baghdad in 1625 and was present at the siege of Erzerum. In 1633 he made the pilgrimage to Mecca (hence his title Hājji). While serving in the commissariat department at Constantinople, he wrote in Arabic his largest work, the *Bibliographical Encyclopaedia*. After five chapters dealing with the sciences generally, the titles of Arabian, Persian and Turkish books written up to his own time are arranged alphabetically. Sometimes short notes on the author, his date and the introductory words of his work are given. It was edited by G. Flügel with Latin translation (7 vols. Leipzig, 1835-58), and also at Constantinople (1893).

For his life *see* the preface to Flügel's edition; list of his works in C. Brockelmann's *Gesch. d. arabischen Literatur* (1902), vol. ii.

HAKE, EDWARD (fl. 1579), English satirist, was protected by the earl of Leicester, whose policy it was to support the Puritan party, and who no doubt found a valuable ally in so vigorous a satirist of error in clerical places as was Hake. *News out of Paules Churchyard, A Trappe for Syr Monye*, first appeared in 1567 and was re-issued in 1579. The book takes the form of a dialogue between Bertulph and Paul, who meet in the aisles of the cathedral, and is divided into eight "satyrs," dealing with the corruption of the higher clergy and of judges, the greed of attorneys, the tricks of physicians and apothecaries, the sumptuary laws, extravagant living, Sunday sports, the abuse of St. Paul's cathedral as a meeting-place for business and conversation, usury, etc. It is written in rhymed 14-syllable metre.

A bibliography of Hake's works was compiled by C. Edmonds for his edition of the *Nerves* (Isham Reprints, No. 2, 1872).

HAKE, THOMAS GORDON (1809–1895), English poet, was born at Leeds. He studied medicine at St. George's hospital and at Edinburgh and Glasgow. In 1839 he published a prose epic *Vates*, republished in Ainsworth's magazine as *Valdarno*, which attracted the attention of D. G. Rossetti. In after years he became an intimate member of the Rossetti circle. In 1871 he published *Madeline*; 1872, *Parables and Tales*; 1883, *The Serpent Play*; 1890, *New Day Sonnets*; and in 1892 his *Memoirs of Eighty Years*.

HAKE (*Merluccius merluccius*), a fish of the Mediterranean and the Atlantic coast of Europe, most abundant south of the British Isles. It differs from other fishes of the cod family in skeletal characters, and is, perhaps, best placed in a separate family. It is a slender fish, with long, acute snout, large terminal mouth, and sharp teeth, and reaches a length of 4 ft.; it is a voracious fish, living in rather deep water; the flesh is soft. Other species are known from both coasts of North America, and from Chile and Patagonia, South Africa and New Zealand.

HAKING, RICHARD CYRIL BYRNE, K.C.B. (1916), K.C.M.G. (1918) (1862–), British general, who was born on Jan. 24, 1862. He entered the army in 1881, and served in Burma (1885–7), in Ireland (1898–9) and in South Africa (1899–1901). From 1901 to 1906 he held a post in the staff college. When the World War broke out he had won the rank of brigadier-general, and in 1914 was promoted major-general in command of the 5th brigade. In 1915 he was promoted lieutenant-general and given command of the 1st division, and from 1915 to 1918 commanded the XI. corps. After the war he was appointed chief of the British section of the armistice commission at Spa, until 1919, when he went to Russia and the Baltic provinces in command of British military missions. After commanding the Allied troops in East Prussia and Danzig (1920), he was appointed (1921) high commissioner for the League of Nations in Danzig, a post which he held until 1923. He then held the command of the British troops in Egypt until his retirement in 1927. He was promoted general in 1925.

HAKKAS ("Guests," or "Strangers"), a people of S.W. China, chiefly found in Kwang-Tung, Fu-Kien and Formosa. Their origin is doubtful. They may be related to the Burmese and Siamese. According to their tradition, they were in Shantung and northern China as early as the 3rd century B.C. In disposition, appearance and customs they differ from the true Chinese. They speak a distinct dialect. Their women do not compress their feet, and move freely about in public.

HAKLUYT, RICHARD (c. 1553–1616), British geographer, was born in or near London about 1553. The Hakluys were of Welsh extraction, not Dutch as has been supposed. They appear to have settled in Herefordshire as early as the 13th century. The family seat was Eaton, 2 m. S.E. of Leominster. Hugo Hakelute was returned M.P. for that borough in 1304–05. Richard went to school at Westminster, where he was a queen's scholar; while there his future bent was determined by a visit to his cousin and namesake, Richard Hakluyt of the Middle Temple. His cousin's discourse, illustrated by "certain bookes of cosmographie, an universall mappe, and the Bible," made young Hakluyt resolve to "prosecute that knowledge and kind of literature." He entered Christ Church, Oxford, in 1570, and shortly after taking his M.A. (1577), he began at Oxford the first public lectures in geography that "showed both the old imperfectly composed and the new lately reformed mappes, globes, speares, and other instruments of this art."

Hakluyt's *Divers Voyages touching the Discoverie of America* (1582) brought him to the notice of Lord Howard of Effingham, and so to that of Sir Edward Stafford, Lord Howard's brother-in-law; accordingly at the age of thirty, being acquainted with "the chiefest captaines at sea, the greatest merchants, and the best mariners of our nation," he was selected as chaplain to Stafford, English ambassador at Paris (1583). In accordance with the instructions of Secretary Walsingham, he occupied himself chiefly in collecting information of the Spanish and French movements,

and "making diligent inquirie of such things as might yield any light unto our western discoverie in America." The results are embodied in his *A particuler discourse concerning Western discoveries written in the yere 1584, by Richard Hackluyt of Oxforde, at the requeste and direction of the righte worshipfull Mr. Walter Raghly before the comynge home of his twoo barkes*. This long-lost ms. was at last printed in 1877. Its object was to recommend the enterprise of planting the English race in the unsettled parts of North America. Hakluyt's other works consist mainly of translations and compilations. He revisited England in 1584, laid before Queen Elizabeth a copy of the *Discourse* "along with one in Latin upon Aristotle's *Politicks*," and obtained, two days before his return to Paris, the grant of the next vacant prebend at Bristol, to which he was admitted in 1586 and held with his other preferments till his death.

While in Paris Hakluyt translated the ms. journal of Laudonnière, the *Histoire notable de la Florida, as A notable historie containing foure voyages made by certayne French captaynes into Florida* (London, 1587, 4to.). *De orbe novo Petri Martyris Anglerii decades octo illustratae labore et industria Richardi Hackluyti* (Paris, 1588) contains the exceedingly rare copperplate map dedicated to Hakluyt and signed F. G. (supposed to be Francis Gualle); it is the first on which the name of "Virginia" appears.

In 1588 Hakluyt finally returned to England, after a residence in France of nearly five years. In 1589 he published the first edition of his chief work, *The Principall Navigations, Voiages and Discoveries of the English Nation* (fol., London, 1 vol.). In the preface to this we have the announcement of the intended publication of the first terrestrial globe made in England by Molyneux. In 1598–1600 appeared the final, reconstructed and greatly enlarged edition of *The Principal Navigations, Voyages, Traffiques and Discoveries of the English Nation* (fol., 3 vols.). Some few copies contain an exceedingly rare map, the first on the Mercator projection made in England according to the true principles laid down by Edward Wright. Hakluyt's invaluable collection has been truly called the "prose epic of the modern English nation." In 1601 Hakluyt edited a translation from the Portuguese of Antonio Galvano, *The Discoveries of the World* (4to., London). In the same year his name occurs as an adviser to the East India Company, supplying them with maps, and informing them as to markets. Hakluyt received many preferments: a Suffolk rectory, the archdeaconry of Westminster, a chaplaincy at the Savoy, the prospective living of Jamestown, Virginia, and the rectory of Gedney, Linc. He was one of the chief promoters of the petition to the king for patents to colonize Virginia. He was also a leading adventurer in the London or South Virginia Company. His last publication was a translation of Fernando de Soto's discoveries in Florida, entitled *Virginia richly valued by the description of Florida her next neighbour* (1609). This work was intended to encourage the young colony of Virginia; to Hakluyt, it has been said, "England is more indebted for its American possession than to any man of that age." At the suggestion of Hakluyt, Robert Parke translated Mendoza's *History of China* (London, 1588–1589) and John Pory made his version of *Leo Africanus* (*A Geographical History of Africa*, London, 1600). Hakluyt died in 1616 (November 23) and was buried in Westminster Abbey (November 26); by an error in the abbey register his burial is recorded under the year 1626.

A number of his mss., sufficient to form a fourth volume of his collections of 1598–1600, fell into the hands of Samuel Purchas, who inserted them in an abridged form in his *Pilgrimes* (1625–26, fol.). Others are preserved at Oxford (Bib. Bod. ms. Seld. B. 8), which consist chiefly of notes gathered from contemporary authors.

Besides the mss. or editions noticed in the text (*Divers Voyages* (1582); *Particuler Discourse* (1584); Laudonnière's *Florida* (1587); Peter Martyr, *Decades* (1587); *Principal Navigations* (1589 and 1598–1600) reprinted in 8 vols. (1927); Galvano's *Discoveries* (1601); De Soto's Florida record, the *Virginia richly valued* (1609, etc.), we may notice the Hakluyt Society's London edition of the *Divers Voyages* in 1850, the edition of the *Particuler Discourse*, by Charles Deane in the *Collections of the Maine Historical Society* (Cambridge, Mass., 1870, with an introduction by Leonard Woods); also, among modern issues of the *Principal Navigations*, those of 1809 (5 vols., with much additional matter), and of 1903–05 (Glasgow, 12 vols.). The new title-

page issued for the first volume of the final edition of the *Principal Navigations*, in 1599, merely cancelled the former 1598 title with its reference to the Cadiz expedition of 1596; but from this has arisen the mistaken supposition that a new edition was then (1599) published. Hakluyt's *Galvano* was edited for the Hakluyt Society by Admiral C. R. D. Bethune in 1862. This Society, which was founded in 1846 for printing rare and unpublished voyages and travels, includes the Glasgow edition of the *Principal Navigations* in its extra series, as well as C. R. Beazley's edition of *Carpini, Rubruquis*, and other mediaeval texts from Hakluyt (Cambridge, 1903, 1 vol.). Reckoning in these and an issue of Purchas's *Pilgrimes* by the Glasgow publisher of the Hakluyt of 1903-05, the society has now published or "fathered" 150 vols. See also *Voyages of the Elizabethan Seamen to America, being Select Narratives from the Principal Navigations*, by E. J. Payne (Oxford, 1880; 1893; new edition by C. R. Beazley, 1907).

For Hakluyt's life the dedications of the 1589 and 1598 editions of the *Principal Navigations* should be especially consulted; also Winter Jones's introduction to the Hakluyt Society edition of the *Divers Voyages*; Fuller's *Worthies of England*, "Herefordshire"; *Oxford Univ. Reg.* (Oxford Hist. Soc.), ii., iii. 39; *Historical MSS. Commission, 4th report, appendix*, p. 614, the last giving us the Towneley mss. referring to payments (prizes?) awarded to Hakluyt when at Oxford, May 12th and June 4th, 1575.

HAKODATE, a town on the south of the island of Yezo, Japan, for many years regarded as the capital of the island until Sapporo was officially raised to that rank. Pop. (1925) 163,972. The town is built along the north-western base of a rocky promontory (1,157 ft. in height) which forms the eastern boundary of a spacious bay, and is united to the mainland by a narrow sandy isthmus. The summit of the rock, called the Peak, is crowned by a fort. Hakodate is one of the ports originally opened to foreign trade. The Bay of Hakodate, an inlet of Tsugaru Strait, is completely land-locked, easy of access and spacious, with deep water almost up to the shore. The Russians formerly used Hakodate as a winter port. The staple exports are beans, pulse and peas, marine products, sulphur, furs and timber; the staple imports, comestibles (especially salted fish), kerosene and oil-cake. Frequent steamers connect Hakodate and Yokohama and other ports, and there is daily communication with Aomori, 56 m. distant, whence there is rail connection with Tokyo. Hakodate was opened to American commerce in 1854.

HAKO-NIWA (box-garden or box-yard) is a kind of *bon-tei* or *bon-kei* (*qq.v.*) generally acknowledged to be a development of *hako-niwa*. It is therefore sometimes difficult to distinguish them. *Hako-niwa* is a small landscape garden in a wooden box, which nowadays is often replaced by a more durable concrete with one or two holes in the bottom for drainage, though the vessel is usually larger and deeper than that used for *bon-kei*. Planted with dwarf trees, bushes and grass, and embellished with natural stones and miniature figures, houses, towers, bridges, etc., of baked clay or bronze, it generally has a small pond for tiny goldfishes. The box-garden is usually placed outside the window or at a corner of the veranda. Unlike *bon-kei*, which is quickly made and remade according to fancy, the *hako-niwa* is meant to last longer and some require years for their completion as in the case of the real landscape garden. Though *hako-niwa*, in its varying forms, has existed in Japan for centuries, it has come to be associated more or less with the people, and has not attained the dignity enjoyed by *bon-seki*, *bon-sai* or *ike-bana* (*qq.v.*) and is often no more than a childish amusement. Especially since the popularity of *bon-kei*, the *hako-niwa* has declined, though it is still to be seen in shop windows, at the entrance to workshops, in factory dormitories, or in humble homes.

HAL, a town of Brabant, Belgium, about 10 m. S.W. of Brussels, situated on the river Senne and the Charleroi canal. Pop. (1925) 16,054. The church of Notre Dame, formerly dedicated to St. Martin is a good example of pure Gothic, begun in 1341 and finished in 1409. Its alabaster altar, by J. Mone, was completed in 1533. The bronze font dates from 1446. In the treasury of the church are costly gifts from illustrious persons. The church is chiefly celebrated, however, for its miraculous image of the Virgin. Legend says that during a siege the bullets fired into the town were caught in the folds of the dress. The hôtel de ville dates from 1616 and has been restored.

HALA, a town of British India in Hyderabad district, Sind. Pop. (1921) 5,757. It has long been famous for its glazed pottery

and tiles, made from a fine clay obtained from the Indus, mixed with powdered flints.

HALAESA, an ancient town on the north coast of Sicily, about 14 m. E. of Cephaloedium (Cefalu), to the east of the modern Castel di Tusa, founded in 403 B.C. by Archonides, tyrant of Herbita, whose name it sometimes bore. It was the first town to surrender to the Romans in the First Punic War and was granted freedom and immunity from tithe. It became a Roman port of some importance. (T. A.)

HALAKHA: see HAGGĀDAH.

HALBERSTADT, a town in the Prussian province of Saxony, 56 m. by rail N.W. of Halle, and 29 S.W. of Magdeburg. It lies in a fertile country north of the Harz mountains, on the Holzemme, at the junction of railways to Halle, Goslar and Thale. Pop. (1925) 48,125. The history of Halberstadt begins with the transfer to it, in 820, of the see founded by Charlemagne at Seligenstadt. At the end of the 10th century it received a charter and the bishops were granted by the emperors the right to exercise temporal jurisdiction over their see, which became one of the chief ecclesiastical principalities of the Empire. In 1648 it was converted by the treaty of Westphalia into a secular principality for the elector of Brandenburg. By the treaty of Tilsit in 1807 it was annexed to the kingdom of Westphalia, but came again to Prussia on the downfall of Napoleon. The town has many old houses decorated with wood-carving still surviving. The Gothic cathedral (now Protestant), dating from the 13th and 14th centuries, is remarkable for the great height of the interior, with its slender columns and lofty, narrow aisles. The treasure, preserved in the former chapter-house, is rich in reliquaries, vestments and other objects of mediaeval church art. Among the other churches the only one of special interest is the Liebfrauenkirche (Church of Our Lady), a basilica, with four towers, in the later Romanesque style, dating from the 12th and 13th centuries and restored in 1848, containing old mural frescoes and carved figures. The other old buildings are the town hall, of the 14th century and restored in the 17th century, with a crypt, and the Petershof, formerly the episcopal palace, but now utilized as law courts and a prison. The principal manufactures of the town are sugar, cigars, paper, gloves, boots, leather and machinery. About a mile and a half distant is the Klusberge, with prehistoric cave-dwellings in the sandstone rocks.

HALBERT, HALBERD or **HALBARD**, a weapon consisting of an axe-blade balanced by a pick and having an elongated pike-head at the end of the staff, which was usually about 5 or 6 ft. in length. The utility of such a weapon in the wars of the later middle ages was that it gave the foot soldier the means of dealing with an armoured man on horseback. The pike could do no more than keep the horseman at a distance. This ensured security for the foot soldier but did not enable him to strike a mortal blow, for which firstly a long-handled and secondly a powerful weapon, capable of striking a heavy cleaving blow, was required. Several different forms of weapon responding to these requirements are described and illustrated below; it will be noticed that the thrusting pike is almost always combined with the cutting-bill hook or axe-head, so that the individual billman or halberdier should not be at a disadvantage if caught alone by a mounted opponent, or if his first descending blow missed its object. It will be noticed further that, concurrently with the disuse of complete armour and the development of firearms, the pike or thrusting element gradually displaces the axe or cleaving element in these weapons, till at last we arrive at the court halberts and partizans of the late 16th and early 17th centuries and the so-called "halbert" of the infantry officer and sergeant in the 18th, which can scarcely be classed even as partizans.

Figs. 1-6 represent types of these long cutting, cut and thrust weapons of the middle ages, details being omitted for the sake of clearness. The most primitive is the *voulge* (fig. 1), which is simply a heavy cleaver on a pole, with a point added. The next form, the *gisarme* or *guisarme* (fig. 2), appears in infinite variety but is always distinguished from *voulges*, etc., by the hook, which was used to pull down mounted men, and generally resembles the agricultural bill-hook of to-day. The *glaiue* (fig. 3 is Late Ger-

man) is a broad, heavy, slightly curved sword-blade on a staff; it is often combined with the hooked gisarme as a *glaive-gisarme* (fig. 4, Burgundian, about 1480). A *gisarme-voulge* is shown in fig. 5 (Swiss, 14th century).

The weapon best known to Englishmen is the *bill*, which was originally a sort of scythe-blade, sharp on the concave side (whereas the glaive has the cutting edge on the convex side), but in its best-known form it should be called a bill-gisarme (fig. 6). The *partizans*, *ranseurs* and *halberts* proper developed naturally from the earlier types. The feature common to all, as has been said, is the combination of spear and axe. In the halberts the axe predominates, as the examples (fig. 10, Swiss, early 15th century; fig. 11, Swiss, middle 16th century; and fig. 12, German court halbert of the same period as fig. 11) show. In the *partizan* the pike is the more important, the axe-heads being reduced to little more than an ornamental feature. A south German specimen (fig. 9, 1615) shows how this was compensated by the broadening of the spear-head, the edges of which in such weapons were sharpened. Fig. 8, a service weapon of simple form, merely has projections on either side, and from this developed the *ranseur* (fig. 7), a partizan with a very long and narrow point, like the blade of a rapier, and with fork-like projections intended to act as "sword-breakers," instead of the atrophied axe-heads of the partizan proper.

The halbert played almost as conspicuous a part in the military history of Middle Europe during the 15th and early 16th centuries as the pike. But, even in a form distinguishable from the voulge and the glaive, it dates from the early part of the 13th century, and for many generations thereafter it was the special weapon of the Swiss. It was also in the 15th and 16th centuries that the halberts became larger, and the blades were formed in many varieties of shape, often engraved, inlaid or pierced in open work, and exquisitely finished as works of art. This weapon was in use in England from the reign of Henry VII. to the reign of George III., when it was still carried (though in shape it had certainly lost its original characteristics, and had become half partizan and half pike) by sergeants in the guards and other infantry regiments. It is still retained as the symbol of authority borne before the magistrates on public occasions in some of the burghs of Scotland. The Lochaber axe may be called a species of halbert furnished with a hook on the end of the staff at the back of the blade. The *godendag* (Fr. *godendart*) is the Flemish name of the halbert in its original form.

HALDANE, ELIZABETH SANDERSON (1862-), English author, daughter of Robert Haldane of Cloanden, was born in 1862 and educated at home. She took up the nursing profession, and became vice-chairman of the Territorial nursing service. She was also manager of Edinburgh royal infirmary for some years. She took an active part in public life, and served on the royal commission on the civil service, and on several advisory committees. She was the first woman to be made a justice of the peace in Scotland. In addition to her public work, she studied philosophy, obtained the degree of LL.D. at St. Andrews university, and wrote several books on the philosophers, as well as many articles in various periodicals. Her publications

include: *The Wisdom and Religion of a German Philosopher* (1897); *Life of James Ferrier* (1899); *Life of Descartes* (1905); *Descartes' Philosophical Works* (with Prof. Ross, 1912); *British Nurse in Peace and War* (1923); *George Eliot and her Times* (1927); and a translation, with Miss F. Simson, of Hegel's *History of Philosophy* (3 vols., 1892).

HALDANE, JOHN SCOTT (1860-), English scientist, was born in Edinburgh in 1860, and educated at Edinburgh academy and at the universities of Edinburgh and Jena. From 1885 he was engaged on scientific investigation and teaching, and is honorary professor and director of the mining research laboratory of Birmingham university, president of the Institution of Mining Engineers, and Gifford lecturer at the University of Glasgow. He has been in charge of several Government enquiries on public health questions, and has served on several Royal commissions. His numerous publications include: *Essays in Philosophical Criticism* (1883, joint-author); *Mechanism, Life and Personality* (1913); *Organism and Environment* (1917); *The New Physiology* (1919); *Respiration* (1922); *The Sciences and Philosophy* (1929); Blue-books on the causes of death in colliery explosions (1895), and on various other subjects.

HALDANE, RICHARD BURDON, 1ST VISCOUNT, (1856-1928), British statesman and philosopher, born July 30, 1856, third son of Robert Haldane of Cloanden, Perthshire, a writer to the signet. He was educated at Edinburgh academy and the universities of Edinburgh and Göttingen, where he studied philosophy under Lotze. He took first-class honours in philosophy at Edinburgh, and was Gray scholar and Ferguson scholar in philosophy of the four Scottish universities (1876). He was called to the bar in 1879, and took silk in 1890. In 1885 he entered parliament as liberal member for Haddingtonshire, for which he was re-elected continuously up to and including 1910. He was included in 1905 in Sir H. Campbell-Bannerman's cabinet as secretary for war, and carried out the great reorganization of the British army, the value of which was only fully recognized when war came in 1914. The work was done in the face of fierce opposition from those interested in the maintenance of the existing order. By the creation of the Officers' Training Corps in 1909, the universities and schools were able to contribute in the time of need exactly the type of officer required. The Militia had been replaced by a Special Reserve of real value as events showed. The Territorial Army had been created and saved the situation more than once. The general staff was brought into existence by the issue of a special army order, establishing it on the footing it held during the War and after. To Lord Haldane, again, is due the decision of the Dominion Conference in 1907, accepting the principle of an imperial general staff, by which concerted action and intelligent co-operation between armies drawn from all parts of the Empire was made possible. Haldane recognized the place of science in war; to him was due the establishment of the National Physical Laboratory at Teddington, with a special committee charged with experimentation in aircraft and aerial navigation, and he also reconstructed the balloon factory at Farnborough. He economized by cutting out weak units in the army, and made it an effective fighting force. When the storm of controversy was past, he was recognized as the greatest war minister since Cardwell.

In 1910 he was appointed chairman of the royal commission on university education in London. The report (Cd. 6717) dated Dec. 1911 dealt faithfully and vigorously with the problems placed before it, though effect has not yet been given to its recommendations. In March 1911 he was raised to the peerage and appointed a member of the judicial committee of the privy council and aided in raising the committee to a commanding position in the empire. His judgments, based on a philosophical reading of law, placed him personally in the great line of British jurists.

Haldane was responsible, under the cabinet, for the conversation with France which laid down the lines of British and French co-operation in case of need. Simultaneously he acted as the agent of the cabinet in seeking an understanding with Germany which would prevent the outbreak of war. In 1906 he attended the German military manoeuvres, and at that time he visited the German War Office, and studied German staff methods. On Feb. 8-12,

TYPES OF HALBERT

1, Voulge; 2, gisarme or guisarme; 3, glaive; 4, glaive-gisarme; 5, gisarme-voulge; 6, bill-gisarme; 7, ranseur; 8, Service halbert; 9, German partizan, 1615; 10, Swiss, early 15th century; 11, Swiss, middle 16th century; 12, German court halbert, middle 16th century

1912, he went on a definitely diplomatic mission to Berlin, with instructions to discuss all outstanding questions, including Morocco, the Baghdad railway and naval armaments. On his return he reported to the cabinet information he gathered there as to the attitudes and conditions of those then guiding the policy of Germany. Something resulted from the mission, but the war party in Germany prevailed. Haldane accepted the thwarting of the full result he had looked for with characteristic courage and dignified silence. In 1912 he succeeded Loreburn as lord chancellor.

Practical reasons and popular prejudice (his visits to Germany and his known preoccupation with German philosophy were used by the ignorant as a basis for a charge of pro-Germanism) account for his absence from the first Coalition Ministry in 1915, when he received the Order of Merit. He was not given the opportunity of developing in war-time the army of which he had laid the firm foundation in peace-time. He was free—as free as any patriot of his nature and temperament could be in such stressful days—to return to the philosophical studies which had been interrupted by his long term of office. In 1903 he had published his *Pathway to Reality*, the Gifford lectures delivered by him at St. Andrews. They were a restatement of the Hegelian doctrine in the light of modern scientific work. He published in 1921 *The Reign of Relativity*, a masterly presentment of profound, scientific and metaphysical thought, and in 1922, *The Philosophy of Humanism*, an abiding memorial of the dictum *Das Geistige allein ist das Wirkliche*. Always eager to promote national education, Haldane now devoted much time and energy to the Workers' Educational Association, which owed much to his support and counsel.

Haldane was lord chancellor in the Labour Ministry of Ramsay MacDonald (1924), and working chairman of the committee of imperial defence, where his experience, tact and indefatigable industry were invaluable, and, on the fall of the Labour Ministry, Baldwin invited him to continue his long association with it. The report of the Machinery of Government committee (Cd. 9230, 1918), of which Haldane was chairman, pointed out that "Further provision is needed in the sphere of civil government for the continuous organization of knowledge and the prosecution of research in order to furnish a proper basis of policy." Accepting this declaration of principle, Baldwin established in 1925 the committee of civil research, on which Haldane served as a member. Thus, through every department of State, in education, in university life, in the army, in the law and in industry are found the effects of his master mind, of his clear vision, of his resolute adherence to first principles and of his practical philosophy. Elected first chancellor of Bristol university, he was also lord rector of Edinburgh, and received many honorary degrees. His book, *Before the War*, gives an account of his political activities at that time. Haldane never married. He died at Cloan on Aug. 19, 1928.

His *Selected Addresses* appeared in 1928, his *Autobiography* in 1929.

HALDANE, ROBERT (1764–1842), Scottish divine, was born in London on Feb. 28, 1764. In Dec. 1797 he joined his brother J. A. Haldane and others in the formation of the "Society for the Propagation of the Gospel at Home," in building chapels or "tabernacles" for congregations, in supporting missionaries, and in maintaining institutions for the education of young men to carry on the work of evangelization. He also initiated a plan for evangelizing Africa by bringing over native children to be trained as Christian teachers to their own countrymen. He died on Dec. 12, 1842.

His treatise *On the Inspiration of Scripture* (1828), passed through many editions, and a later *Exposition of the Epistle to the Romans* (1835), was frequently reprinted, and translated into French and German. See Alex. Haldane, *Memoirs of R. and J. A. Haldane* (1852).

HALDEN, a town in the county of Östfold in the south of Norway. It is situated at the mouth of the river Tista near the border of Sweden. Pop. (1927), 11,160. In early times there existed a settlement called Halden on the same site. This settlement gained its charter under King Fredrik II., who called the town Fredrikshald, but in 1928 the name was changed again to Halden. During the frequent wars with Sweden it was especially exposed to Swedish attacks, and a fort, Fredriksten, was built in 1644 for the defence of the town. The most important indus-

tries of Halden are in connection with the great timber production of the neighbourhood. There are many sawmills along the river, also mills for wood-pulp and paper. Other industries are the manufacture of boots and shoes and textiles. In the neighbouring district there are many quarries and granite is exported. The town is connected by rail with Oslo and other towns of the county, and has both coasting and foreign trade.

HALDIMAND, SIR FREDERICK (1718–1791), British general and administrator, was born at Yverdun, Neuchâtel, Switzerland, on Aug. 11, 1718, of Huguenot descent. He entered the British service in 1754 and later was naturalized as a British citizen. In 1778 he succeeded Sir Guy Carleton (afterwards Lord Dorchester) as governor-general of Canada. His measures against French sympathizers with the Americans have incurred extravagant strictures from French-Canadian historians, but he really showed moderation as well as energy. In 1785 he returned to London. He died at his birthplace on June 5, 1791.

See a life by Jean McIlwraith in the "Makers of Canada" series (Toronto, 1904). His correspondence and Diary are preserved in the Canadian Archives.

HALE, EDWARD EVERETT (1822–1909), American author, was born in Boston April 3, 1822. He was of a distinguished family, his father being proprietor and editor of the *Boston Daily Advertiser*; his uncle, Edward Everett, the orator and statesman; and his great-uncle, Nathan Hale, the martyr spy. He graduated from Harvard in 1839; studied theology privately while teaching at the Boston Latin School; began to preach in 1842; and became pastor of the church of the Unity, Worcester (Mass.) (1846–56), and of the South Congregational (Unitarian) church, Boston, in 1856. While he was pastor emeritus of the latter church he was named in 1903 chaplain of the United States Senate. He died at Roxbury (Boston, Mass.), June 10, 1909. His forceful personality, organizing genius, and liberal practical theology, together with his deep interest in the anti-slavery movement, popular education, and the working-man's home, were active for half a century in raising the tone of American life. He was a voluminous contributor to newspapers and magazines, an editor of several periodicals, and the author or editor of more than sixty books—fiction, travel, sermons, biography, and history. He first came into notice as a writer in 1859, when he contributed the short story "My Double and How He Undid Me" to the *Atlantic Monthly*. He afterwards published in the same periodical other tales, the best known of which was "The Man Without a Country" (1863), which did much to strengthen the Union cause, and in which, as in some of his other non-romantic tales, he employed a minute realism which has led his readers to suppose the narrative a record of fact. The story *Ten Times One Is Ten* (1870) led to the formation among young people of "Lend-a-Hand Societies" and "Harry Wadsworth Clubs." Out of the romantic story of the Waldenses, *In His Name* (1873), there similarly grew several other organizations for religious work, such as the "King's Daughters."

Among Hale's other books are *Kansas and Nebraska* (1854), prepared as a contribution to the Kansas Crusade; *If, Yes, and Perhaps* (1868), stories and essays; *The Ingham Papers* (1869); *His Level Best and Other Stories* (1870); *Sybaris and Other Homes* (1869); *Philip Nolan's Friends* (1876), a sequel to *The Man Without a Country*; *Christmas in Narragansett* (1884); *East and West* (1892; also published as *The New Ohio*); *For Fifty Years* (1893), poems; *Ralph Waldo Emerson* (1899); and *We, the People* (1903). The most charming books of his later years were *A New England Boyhood* (1893), *James Russell Lowell and His Friends* (1899) and *Memories of a Hundred Years* (1902). *His Works*, in ten volumes, appeared in 1898–1901.

See E. E. Hale, Jr., *The Life and Letters of Edward Everett Hale* (1917).

HALE, GEORGE ELLERY (1868–), American astronomer, was born at Chicago (Ill.), on June 29, 1868. He graduated at the Massachusetts Institute of Technology in 1890, and also carried on research work at the Harvard College observatory (1889–90) and the University of Berlin (winter, 1893–94). In 1888–91 he organized the Kenwood observatory in Chi-

cago, where he invented and developed the spectroheliograph, an instrument for photographing the sun in monochromatic light. (See SPECTROHELIOGRAPH.) In 1892, when he became associate professor of astrophysics (later professor) in the University of Chicago, he began the organization of the Yerkes observatory, of which he was director until 1904. In 1895 he established the *Astrophysical Journal*, an international review of spectroscopy and astronomical physics. In 1904 he organized the Mt. Wilson observatory of the Carnegie Institution of Washington, and was its director until 1923, when he became honorary director. In 1916 he was chairman of the committee of the National Academy of Sciences that organized the National Research council. He was chairman of this council throughout the World War, becoming honorary chairman in 1918. As foreign secretary of the National Academy of Sciences for many years he took an active part in international affairs, especially in the organization and work of the International Union for Co-operation in Solar Research, the International Astronomical Union, the International Research council, and the International Committee on Intellectual Co-operation of the League of Nations. His researches in solar physics and stellar evolution, and his discoveries of solar vortices, the magnetic fields in sun-spots, and the general magnetic field of the sun, have been recognized by the award of many medals and prizes and honorary degrees, and by his election as a foreign member of the Institute of France, the Royal Society of London, and most of the leading European academies of science.

He assisted in the organization of the California Institute of Technology and the Huntington Library and Art Gallery, of which he is a trustee, and in the improvement of the City of Pasadena as a member of the City Planning commission. He was engaged in 1927 at his solar laboratory in Pasadena in the development of the spectro-helioscope, a new instrument which renders possible the visual observation of the solar atmosphere.

He wrote a large number of scientific papers, *The Study of Stellar Evolution* (1908), *Ten Years' Work of a Mountain Observatory* (1915), *The New Heavens* (1923), *The Depths of the Universe* (1924), and *Beyond the Milky Way* (1926).

HALE, HORATIO EMMONS (1817-1896), American ethnologist, was born in Newport, N.H., on May 3, 1817. He was the son of David Hale, a lawyer, and of Sarah Josepha Hale (1790-1889), a popular poet, who is supposed to have been the first to suggest the national observance of Thanksgiving Day. The son graduated in 1837 at Harvard, and during 1838-42 was philologist to the U.S. exploring expedition, which under Capt. Charles Wilkes sailed around the world. Of the reports of that expedition Hale prepared the sixth volume, *Ethnography and Philology* (1846), which is said to have "laid the foundations of the ethnography of Polynesia." He was admitted to the Chicago bar in 1855, and in the following year removed to Clinton, Ont., Canada, where he practised his profession, and where he died on Dec. 28, 1896. His works include *Indian Migrations as Evidenced by Language* (1882); *The Origin of Language and the Antiquity of Speaking Man* (1886); *The Development of Language* (1888); and *Language as a Test of Mental Capacity: Being an Attempt to Demonstrate the True Basis of Anthropology* (1891). He also edited for Brinton's "Library of Aboriginal Literature" the *Iroquois Book of Rites* (1883).

See "Horatio Hale" by D. G. Brinton in *The American Anthropologist*, vol. 10 (1897).

HALE, JOHN PARKER (1806-1873), American statesman, was born at Rochester, N.H., on March 31, 1806. He graduated at Bowdoin college in 1827 and was admitted to the New Hampshire bar in 1830. In 1843-45 he was a Democratic member of the national House of Representatives. In Jan. 1845, he refused in a public statement to obey a resolution of the State legislature directing him and his New Hampshire associates in Congress to support the cause of the annexation of Texas, a Democratic measure which Hale regarded as being distinctively in the interest of slavery. The Democratic State convention was at once reassembled, Hale was denounced, and his renomination was withdrawn. Hale then set out in the face of apparently hopeless odds to win over his State to the anti-slavery cause. The re-

markable canvass which he conducted is known in the history of New Hampshire as the "Hale Storm of 1845." The election resulted in the choice of a legislature controlled by the Whigs and the independent Democrats, Hale himself being chosen as a member of the State house of representatives, of which in 1846 he was speaker. He is remembered, however, chiefly for his long service in the United States Senate, of which he was a member from 1847 to 1853 and again from 1855 to 1865. At first he was the only out-and-out anti-slavery senator, but in 1849 Salmon P. Chase and William H. Seward, and in 1851 Charles Sumner joined him, and the anti-slavery cause became for the first time a force to be reckoned with in that body. He was one of the organizers of the Republican Party, and during the Civil War was an eloquent supporter of the Union and chairman of the Senate naval committee. From 1865 to 1869 he was United States minister to Spain. He died at Dover, N.H., on Dec. 19, 1873. In 1892 a statue of Hale was erected in front of the capitol in Concord, New Hampshire.

HALE, SIR MATTHEW (1609-1676), lord chief justice of England, was born on Nov. 1, 1609, at Alderley, Gloucestershire. Left an orphan when five years old, he was placed by his guardian under the care of the Puritan vicar of Wotton-under-Edge, with whom he remained till his 16th year, when he entered Magdalen Hall, Oxford. At Oxford, Hale studied for several terms with a view to holy orders, but, attracted by a company of strolling players, he threw aside his studies, and plunged carelessly into gay society. He resolved to trail a pike as a soldier under the prince of Orange in the Low Countries. But, before leaving England, he had to go to London to defend his patrimony. His leading counsel was the celebrated Serjeant Glanville (1586-1661), who detected his great ability and persuaded him to enter Lincoln's Inn (1629). Hale devoted himself to his legal studies with intense application. The rules which he laid down for himself prescribed 16 hours work a day. He read over and over again all the year-books, reports and law treatises in print, and carefully studied the extant records from the foundation of the English monarchy down to his own time. Hale dedicated part of his time to the study of pure mathematics, to investigations in physics and chemistry, and even to anatomy and architecture; and this varied learning enhanced considerably the value of many of his judicial decisions.

He was called to the bar in 1637, and almost at once found himself in full practice. In a very few years he was at the head of his profession. He entered public life at perhaps the most critical period of English history. But amidst the confusion Hale steered a middle course. Taking Pomponius Atticus as his political model, he was persuaded that a man, a lawyer and a judge could best serve his country by holding aloof from partisanship and its violent prejudices. It has been said, but without certainty, that Hale was engaged as counsel for the earl of Strafford; he certainly acted for Archbishop Laud, Lord Maguire, Christopher Love, the duke of Hamilton and others. It is also said that he was ready to plead on the side of Charles I. had that monarch submitted to the court. The parliament having gained the ascendancy, Hale signed the Solemn League and Covenant, and was a member of the famous assembly of divines at Westminster in 1644; but although he would undoubtedly have preferred a Presbyterian form of church government, he had no serious objection to the system of modified Episcopacy proposed by Usher. Hale took the engagement to the Commonwealth as he had done to the king, and in 1653, already serjeant, he became a judge in the court of common pleas. Two years afterwards he sat in Cromwell's parliament as one of the members for Gloucestershire. After the death of the protector, however, he declined to act as a judge under Richard Cromwell, although he represented Oxford in Richard's parliament. At the Restoration in 1660 Hale was graciously received by Charles II., and in the same year was appointed chief baron of the exchequer, and accepted, with extreme reluctance, the honour of knighthood. After holding the office of chief baron for 11 years he was appointed lord chief justice. He retired in 1676 to his native Alderley, where he died on Dec. 25 of the same year.

As a judge Sir Matthew Hale discharged his duties with resolute independence and careful diligence. His sincere piety made him the intimate friend of Isaac Barrow, Archbishop Tillotson, Bishop Wilkins and Bishop Stillingfleet, as well as of the Non-conformist leader, Richard Baxter. He is chargeable, however, with the condemnation and execution of two poor women tried before Lim for witchcraft in 1664, a kind of judicial murder then falling under disuse. He is also reproached with having hastened the execution of a soldier for whom he had reason to believe a pardon was preparing.

Of Hale's legal works the only two of importance are his *Historia placitorum coronae*, or *History of the Pleas of the Crown* (1736); and the *History of the Common Law of England, with an Analysis of the Law*, etc. (1713). Among his numerous religious writings the *Contemplations*, *Moral and Divine*, occupy the first place. One of his most popular works is the collection of *Letters of Advice to his Children and Grandchildren*. He left his valuable collection of mss. and records to the library of Lincoln's Inn. His life has been written by G. Burnet (1682); by J. B. Williams (1835); by H. Roscoe, in his *Lives of Eminent Lawyers*, in 1838; by Lord Campbell, in his *Lives of the Chief Justices*, in 1849; and by E. Foss in his *Lives of the Judges* (1848-70).

HALE, NATHAN (1756-1776), hero of the American Revolution, was born at Coventry, Conn., educated at Yale, and became a school teacher. He joined a Connecticut regiment after the breaking out of the war, and served in the siege of Boston, being commissioned a captain at the opening of 1776. When Heath's brigade departed for New York he went with them, and the tradition is that he was one of a small and daring band who captured a provision sloop from under the very guns of a man-of-war. But on Sept. 21, having volunteered to enter the British lines to obtain information concerning the enemy, he was captured in his disguise of a Dutch school teacher and was hanged the next day. The penalty was in accordance with military law, but young Hale's act was a brave one, and he has always been glorified as a martyr. Tradition attributes to him the saying that he only regretted that he had but one life to lose for his country; and it is said that his request for a Bible and the services of a minister was refused by his captors. There is a fine statue of Hale by Macmonnies in New York.

See H. P. Johnston, *Nathan Hale* (1901); William Ordway Partridge, *Nathan Hale, The Ideal Patriot* (1902); H. P. Johnston, *Nathan Hale, 1776* (New Haven, 1914) and J. C. Root, *Nathan Hale* (1915).

HALE, PHILIP (1854-), American music and dramatic critic, was born at Norwich, Vt., March 5, 1854. He graduated at Yale in 1876, was admitted to the bar at Albany, N.Y., in 1879 and studied music in Germany and France from 1882 to 1887. While he was a church organist (1888-1905) he wrote musical criticism for the *Boston Post* and the *Journal*, and edited first the *Musical Record* and afterwards the *Musical World*. In 1903 he joined the editorial staff of the *Boston Herald*.

HALE, WILLIAM GARDNER (1849-), American classical scholar, was born on Feb. 9, 1849, in Savannah, Georgia. He graduated from Harvard university in 1870 and did graduate work there and at Leipzig and Göttingen; after a tutorship at Harvard he was professor of Latin at Cornell university from 1880 to 1892, when he became professor of Latin and head of the Latin department of the University of Chicago. In 1919 he retired as professor emeritus. From 1894 to 1899 he was chairman, and in 1895-96 first director, of the American School of Classical Studies at Rome. He is best known as an original teacher on questions of syntax. *The Cum-Constructions: Their History and Functions*, which appeared in *Cornell University Studies in Classical Philology* (1887-89), involved him in a controversy with Hoffmann, best summarized in Wetzel's *Der Streit zwischen Hoffmann und Hale* (1892). Hale also published *The Sequence of Tenses in Latin* (1887-88); *The Anticipatory Subjunctive in Greek and Latin* (in *Chicago University Studies in Classical Philology*, 1895); a *Latin Grammar* with C. D. Buck (1903); *The Manuscripts of Catullus* (1908); and various pamphlets on methods. He was associate editor of the *Classical Review* (1895-1907) and of the *Classical Quarterly* after 1907, and president of the American Philological Association (1892-93).

HALEBID, a village in Mysore state, southern India. It is the site of Dorasamudra, the capital of the Hoysala dynasty

founded early in the 11th century. In 1310 and in 1326 it was plundered by the first Mohammedan invader of south India. Two temples, still standing, though never completed and partly ruined, are the finest examples of elaborately carved Chalukyan architecture.

HALES or HAYLES, JOHN (d. 1571), English writer and politician, was a son of Thomas Hales of Hales Place, Halden, Kent. He wrote his *Highway to Nobility* about 1543, and was the founder of a free school at Coventry for which he wrote *Introductiones ad grammaticam*. Hales, who was M.P. for Preston, was the most active of the commissioners appointed in 1548 to redress the evil of the enclosures of land; but he failed to carry his remedial proposals through parliament. When the protector, the duke of Somerset, was deprived of his authority in 1550, Hales left England and lived for some time in Strasbourg and Frankfurt, returning to his own country on the accession of Elizabeth. He was imprisoned for a pamphlet, *A Declaration of the Succession of the Crowne Imperiall of Inglande*, but was quickly released, and died on Dec. 28, 1571. The *Discourse of the Common Weal* (ed. E. Lamond, 1893), described as "one of the most informing documents of the age," and written about 1549, has been attributed to Hales.

Hales is often confused with another John Hales, who was clerk of the hanaper under Henry VIII. and his three immediate successors.

HALES, JOHN (1584-1656), English scholar, frequently referred to as "the ever memorable," was born at Bath on April 19, 1584, educated at Corpus Christi college, Oxford, elected a fellow of Merton in 1605, and in 1612 appointed public lecturer on Greek. In 1618 he went to Holland, as chaplain to the English ambassador, Sir Dudley Carleton. In 1619 he returned to Eton, where he held a fellowship. Andrew Marvell called him "one of the clearest heads and best-prepared breasts in Christendom." His eirenical tract entitled *Schism and Schismatics* (1636) fell into the hands of Archbishop Laud, and in 1639 Hales was made one of Laud's chaplains and also a canon of Windsor. In 1642 he was deprived of his canonry by the parliamentary committee, and two years later was obliged to hide in Eton with the college documents and keys. In 1649 he refused to take the "Engagement" and was ejected from his fellowship. He lived in poverty till his death on May 19, 1656.

See his collected works, ed. Lord Hailes (3 vols., 1763).

HALES, STEPHEN (1677-1761), English physiologist, chemist and inventor, was born at Bekesbourne, Kent, in Sept. 1677. He took holy orders at Cambridge, and in 1708 was presented to the perpetual curacy of Teddington, Middlesex, where he remained all his life, though he subsequently held the rectories of Porlock, Somerset and of Faringdon, Hampshire. In 1717 he was elected fellow of the Royal Society, which awarded him the Copley medal in 1739, and on the death of Sir Hans Sloane in 1753, Hales was chosen foreign associate of the French Academy of Sciences. He died at Teddington on Jan. 4, 1761.

Hales is best known for his *Statical Essays*. The first volume, *Vegetable Statics* (1727), describes experiments in plant-physiology: transpiration, the rate of growth of shoots and leaves, variations in root-force at different times of the day and the nourishment taken in by plants from the air. In his experiments he was able to collect gases over water in vessels separate from those in which they were generated, and thus used what was to all intents a "pneumatic trough." The second volume (1733) on *Haemostatics*, contains important experiments on the mechanical relations of blood-pressure, the velocity of the current and the capacity of the different vessels. With Robert Whytt, Hales showed the necessity of the spinal cord for reflex movements. He also devised a "ventilator" (a modified organ-bellows) by which fresh air could be conveyed into gaols, hospitals and ships' holds, and invented a "sea-gauge" for sounding, and processes for distilling fresh from sea water, for preserving corn from weevils by fumigation with brimstone, for salting animals whole by passing brine into their arteries and for bottling chalybeate waters. His *Admonition to the Drinkers of Gin, Brandy, etc.*, was published anonymously in 1734.

HALESOWEN, market town. Stourbridge parliamentary division. Worcestershire, England, on the G.W. and L.M.S. railways 6½ m. S.W. of Birmingham. Pop. (1921) 4,126. There are extensive iron and steel manufactures. The church of SS. Mary and John the Baptist has rude Norman portions. There are a grammar school (1652) and Bourne college (1883). Close to the town are slight ruins of an Early English Premonstratensian abbey. Within the parish and 2 m. N.W. of Halesowen is Cradley, with iron and steel works, fire-clay works and a large nail and chain industry.

HALEVI, JUDAH BEN SAMUEL (c. 1035–c. 1140), the greatest Hebrew poet of the middle ages, was born in Toledo c. 1035, and died in Palestine after 1140. He wrote a philosophical dialogue in five books, called the *Cuzari*, which has been translated into English by Hirschfeld. This book is based on the historical fact that the Crimean Kingdom of the Khazars adopted Judaism, and the Hebrew poet-philosopher describes what he conceives to be the steps by which the Khazar king satisfied himself as to the claims of Judaism. Like many other mediaeval Jewish authors, Judah Halevi was a physician. His real fame depends on his liturgical hymns, which are the finest written in Hebrew since the Psalter, and are extensively used in the Sephardic rite. He wrote some memorable Odes to Zion, which have been commemorated by Heine. He started for Jerusalem, was in Damascus in 1140, and soon afterwards died.

Excellent English renderings of some of Judah Halevi's poems may be read in Mrs. H. Lucas's *The Jewish Year*, and Mrs. R. N. Solomon's *Songs of Exile*.

HALÉVY, ÉLIE (1870–). French historian, son of Ludovic Halévy (q.v.). was born at Etretat on Sept. 6, 1870. He became in 1893 professor at the Ecole Libre des Sciences Politiques, Paris. He is the author of a brilliant study of English history in the 19th century, dealing more especially with the social and economic side and based on an exhaustive study of the original sources. This *Histoire du peuple anglais au XIX^e siècle* (3 vols., 1913–23) was translated into English (3 vols., 1924–27). The first volume of an *Epilogue* (1895–1914) to this work appeared in 1926.

Halévy's other works include: *La Théorie platonicienne des sciences* (1896) and *La Formation du radicalisme philosophique* (3 vols., 1900–03).

HALÉVY, JACQUES FRANÇOIS FROMENTAL ÉLIE (1799–1862), French composer, was born on May 27, 1799, in Paris, of a Jewish family of the name of Lévy. He studied at the Paris Conservatoire under Berton and Cherubini, and in 1819 gained the grand prix de Rome with his cantata *Herminie*. At Rome he devoted himself to the study of Italian music, and wrote an opera and various minor works. In 1827 his opera *L'Artisan* was performed at the Théâtre Feydeau in Paris, apparently without much success. Other works of minor importance, and now forgotten, followed, amongst which *Manon Lescaut*, a ballet, produced in 1830, deserves mention. In 1834 the Opéra-Comique produced *Ludovic*, the score of which had been begun by Hérold and had been completed by Halévy. In 1835 Halévy composed the tragic opera *La Juive* and the comic opera *L'Éclair*, and on these works his fame is mainly founded. *L'Éclair* is something of a curiosity, being written for two tenors and two sopranis, without a chorus. After these two works he wrote numerous operas of various genres. He died at Nice, on March 17, 1862.

See Léon Halévy, *François Halévy, sa vie, ses œuvres* (1862); and other works by Ch. de Lorbias, Beulé, E. Monnaïs and A. Pongin.

HALÉVY, LUDOVIC (1834–1908), French author, was born in Paris. His father, Léon Halévy (1802–83), was a clever and versatile writer, who tried almost every branch of literature—prose and verse, vaudeville, drama, history—without, however, achieving decisive success in any. His uncle, J. F. Fromental E. Halévy (q.v.), was for many years associated with the opera; hence the double and early connection of Ludovic Halévy with the Parisian stage. At 18 he entered the civil service, and held various posts, the last being that of secrétaire-rédacteur to the Corps Législatif. In 1865 he retired. Ten years earlier he had become acquainted with the musician Offenbach, who was about

to start a small theatre of his own in the Champs Elysées, and he wrote a sort of prologue, *Entrez, messieurs, mesdames*, for the opening night. Other little productions, produced under the pseudonym of Jules Servières, followed. The name of Ludovic Halévy appeared for the first time on the bills on Jan. 1, 1856. Soon afterwards the unprecedented run of *Orphée aux enfers*, a musical parody, written in collaboration with Hector Crémieux, made his name famous. In the spring of 1860 he was commissioned to write a play for the manager of the Variétés in conjunction with another vaudevillist, Lambert Thiboust. The latter having abruptly retired from the collaboration, Halévy met on the steps of the theatre Henri Meilhac (1831–97), then comparatively a stranger to him. There and then began a connection which was to last over 20 years. Their joint works may be divided into three classes: the *opérettes*, the farces, the comedies. Amongst the most celebrated works of the joint authors were *La Belle Hélène* (1864), *Barbe Bleue* (1866), *La Grande Duchesse de Gerolstein* (1867), and *La Périhole* (1868). After 1870 the vogue of parody rapidly declined. The decadence became still more apparent when Offenbach was no longer at hand to assist the two authors with his quaint musical irony. They then wrote farces of the old type, consisting of complicated intrigues, with which they cleverly interwove the representation of contemporary whims and social oddities. A serious effort was *Frou-frou* (1869), which, owing perhaps to the admirable talent of Aimée Desclée, remains their unique *succès de larmes*.

Meilhac and Halévy will be found at their best in light sketches of Parisian life, *Les Sonnettes*, *Le Roi Candaule*, *Madame attend Monsieur*, *Toto chez Tata*. Both men had wit, humour, observation of character. Meilhac had a ready imagination, a rich and whimsical fancy; Halévy had taste, refinement and pathos of a certain kind. Not less clever than his brilliant comrade, he was more human. Of this he gave evidence in two delightful books, *Monsieur et Madame Cardinal* (1873) and *Les Petites Cardinal*, in which the lowest orders of the Parisian middle class are faithfully described. Halévy's peculiar qualities are even more visible in the simple and striking scenes of the *Invasion*, published soon after the conclusion of the Franco-German War, in *Criquette* (1883) and *L'Abbé Constantin* (1882), two novels, the latter of which went through innumerable editions. Zola had presented to the public an almost exclusive combination of bad men and women; in *L'Abbé Constantin* all are kind and good, and the change was eagerly welcomed by the public. Some enthusiasts rank the *Abbé* with the *Vicar of Wakefield*.

Halévy remained an assiduous frequenter of the Academy, to which he was elected in 1884, the Conservatoire, the Comédie Française, and the Society of Dramatic Authors, but, when he died in Paris on May 8, 1908, he had produced practically nothing for many years.

The *Théâtre* of Meilhac and Halévy was published in 8 vols. (1900–02).

HALF-BEAK, a group of fishes consisting of several species belonging to the family Hemiramphidae, distinguished from the needlefish, which they closely resemble by the shortness of the upper jaw, whence they take their name. The half-beak is a small attractively coloured fish native to the coasts of tropical countries.

HALF-MOON. An early form of counter-guard work in fortification, sometimes known as a demi-lune, built in front of the bastion to protect it from breaching fire. The work usually consisted of two ramparts meeting at an angle with a half moon shaped gorge from which it derived its name. (See further FORTIFICATION AND SIEGECRAFT.)

HALFPENNY, WILLIAM (fl. 1752), English 18th century architectural designer, was also known as Michael Hoare. He published about 20 books dealing almost entirely with domestic architecture and especially with country houses in the Gothic and Chinese fashions of his period. His most influential works were *New Designs for Chinese Temples* (1750–52); *Rural Architecture in the Gothic Taste* (1752); *Chinese and Gothic Architecture Properly Ornamented* (1752); and *Rural Architecture in the Chinese Taste* (1750–52). The first of these books disproves the statement that Thomas Chippendale and Sir Thomas Chambers

introduced the Chinese taste into England. John Halfpenny, said to have been his son, was associated with William in the production of the above-mentioned works.

HALF STOCK, in the United States a name often applied to shares of stock which have a par value of \$50, because most shares of stock have a par value of \$100, which is considered the unit of value. The name does not in any way imply that one is speaking of a half-share of stock, but always of full or entire shares which have the \$50 par value.

HALF-TIMBER WORK, in architecture, a type of construction in which the spaces between structural timber members, such as posts, girts, beams, braces, etc., are filled in with lath and plaster, wattle and daub, or brick work, leaving the structural members exposed to view, either outside or in. Half-timber work is a natural building technique wherever braced frame construction in timber is common. It is thus widely used in farm houses and rural buildings in China and was at one time almost universal throughout northern Europe. It is probably an ancient form. Reliefs on the column of Trajan (A.D. 113) at Rome show that the Romans employed for camp buildings, bridges, etc., wood-framed structures that resemble half-timber. Viollet-le-Duc studied, in 1834, a Romanesque house at Dreux, dating from the middle of the 12th century, whose front was of heavy half-timber work between end walls of stone. In this example, although the great size of the timbers, the round arch forms in solid wood, and the shallow incised decoration, all reveal a crude and tentative technique, the projecting of the upper stories and the use of brackets and braces show, already, typical half-timber forms that were to remain in use for 600 years. By the middle of the 13th century tremendous advances had been made and a house at Chateaudun, of this date, shows delicate members, straightforward design and a much greater area of filling. In the 14th century the development continued towards an ever greater freedom in the arrangement of the timber members, which are placed with more and more regard for decorative effect, yet with none of the fantastic elaborations that were to come. Typical of this work are many lovely examples in Strasbourg and also a chapel at Cronceus, near Troyes, illustrated by Viollet-le-Duc (*Dictionnaire raisonné*, 1861-75, article "Pan de Bois"), in which great charm is achieved by delicate cusped arched windows set between the upright posts, and the simple trusses and wooden ceiling.

HALF-TIMBER. LEFT, FRENCH, 16TH CENTURY; CENTRE, GERMAN, 16TH CENTURY; RIGHT, ENGLISH, 17TH CENTURY

During the 15th and 16th centuries, half-timber work was made lavishly decorative; not only was rich carving applied to brackets and beams, but also buttress forms were carved on the posts, and curved and diagonal braces became common. In northern France and Germany there is much similarity in the half-timber work of this period and many examples exist at Hildesheim, Goslar, Nuremberg and many of the Rhine towns in Germany, and in France at Rouen, Caen, Lisieux, Bayeux and Beauvais. In all of these the vertical posts dominate the design and frequently project markedly from the wall face to carry the decoration already

referred to. Braces are frequently criss-crossed under the windows, and the dimensions of the timber kept delicate.

In England, where most of the extant examples are of the 16th and 17th centuries, the development was along different lines. The area of timber work exposed is proportionately greater than in the examples on the Continent, and in earlier instances, the design was less formalized and made a greater use of large curved braces and ties. The posts are often further apart. Later, and in the more lavish buildings, the use of criss-crossed and cusped elements became common, the contrast between timber and filling developed as a purely decorative idea and many wooden members added for which there was no structural necessity. Of the simpler type, Staple Inn, at Holborn, London, and Newgate house, York (c. 1450) deserve mention; of the more decorative, Speke hall, near Liverpool (17th century), Moreton old hall, Cheshire (1550-59), St. Peter's hospital, Bristol (1607) and Leicester hospital at Warwick (before 1571) are particularly noteworthy.

Half-timbering is used as a decorative motive in many modern houses in England and America. Owing to the difficulty in making true half-timber construction wind and water tight, and the high cost of large timbers, the greater part of this is purely imitation, the apparent timbers being thin boards applied to the face of construction of a different kind. The taste of this is questionable.

(T. F. H.)

HALF-TONE: see PHOTO-ENGRAVING.

HALHED, NATHANIEL BRASSEY (1751-1830), English Orientalist and philologist, was born at Westminster on May 25, 1751. He was educated at Harrow, where he began his intimacy with R. B. Sheridan, continued after he entered Christ Church, Oxford, where, also, he made the acquaintance of Sir William Jones, the famous Orientalist, who induced him to study Arabic. Halhed went out to India as a writer under the East India Company, and here, at the suggestion of Warren Hastings, by whose orders it had been compiled, translated the Gentoo code from a Persian version of the original Sanskrit. This translation was published in 1776 under the title *A Code of Gentoo Laws*. In 1778 he published a Bengali grammar, to print which he set up, at Hugli, the first press in India. It is claimed for him that he was the first writer to call attention to the philological connection of Sanskrit with Persian, Arabic, Greek and Latin. In 1785 he returned to England, and from 1790-1795 was M.P. for Lynton, Hants. A speech in parliament in defence of Richard Brothers (*q.v.*), made it necessary for him to leave the House. He died in London Feb. 18, 1830. His collection of Oriental manuscripts was purchased by the British Museum, and there is an unfinished translation by him of the *Mahābhārata* in the library of the Asiatic Society of Bengal.

HALIBURTON, THOMAS CHANDLER (1796-1865), British writer, long a judge of Nova Scotia, was born in Windsor, Nova Scotia. He was called to the bar in 1820, became a member of the house of assembly, and in 1828 was promoted to the bench as a chief-justice of the common pleas. In 1829 he published *An Historical and Statistical Account of Nova Scotia*. He is remembered as the creator of Sam Slick in the series of sketches entitled *The Clockmaker, or Sayings and Doings of Samuel Slick of Slickville* (1837). A second series followed in 1838, and a third in 1840. *The Attaché, or Sam Slick in England* (1843-44), was the result of a visit there in 1841. In 1840 he was promoted to be a judge of the supreme court; but within two years he resigned and removed to England. He was M.P. for Launceston from 1859 to 1865.

A memoir of Haliburton, by F. Blake Crofton, appeared in 1889.

HALIBUT (*Hippoglossus vulgaris*), the largest of the flat fishes, reaching a length of 10 feet. It is found in the north Atlantic and north Pacific, and extends into the Arctic ocean, but is not certainly circumpolar. The eyes are on the right side, and the mouth is large; the body is longer and less compressed than in other flat fishes. The halibut feeds on other fishes. It is a valued food fish, with very firm white flesh.

HALICARNASSUS (mod. *Budrum*), an ancient Greek city on the south-west coast of Caria, Asia Minor, on the Ceramic Gulf or Gulf of Cos. It originally occupied only the small island

of Zephyria close to the shore (which now has the great castle of St. Peter, built by the Knights of Rhodes in 1404), but in course of time this island was united to the mainland and the city extended so as to incorporate Salmacis, an older town of the Leleges and Carians.

About the foundation of Halicarnassus various traditions were current; but they agree as to its being a Dorian colony, and the figures on its coins, such as the head of Medusa, Athena and Poseidon, or the trident, support the statement that the mother cities were Troezen and Argos. The inhabitants appear to have accepted Anthes as their legendary founder, and were proud of the title of Antheadae. At an early period Halicarnassus was a member of the Doric Hexapolis, which included Cos, Cnidus, Lindus, Camirus and Ialysus; but owing to the lapses of Agasicles, one of its citizens, the city was cut off from the league. In the early 5th century Halicarnassus was under the sway of Artemisia, who made herself famous at the battle of Salamis. Halicarnassus and other Dorian cities of Asia were afterwards to some extent absorbed by the Delian League, but the peace of Antalcidas in 387 made them subservient to Persia; and it was under Mausolus, a Persian satrap who assumed independent authority, that Halicarnassus attained its highest prosperity. Mausolus increased the population of Halicarnassus by the inhabitants of six towns of the Leleges. He was succeeded by Artemisia, whose magnificence has been perpetuated by the "Mausoleum," the monument she erected to her husband's memory. (See MAUSOLUS.) One of her successors, Pixodarus, tried to ally himself with the rising power of Macedon.

Alexander, as soon as he had reduced Ionia, summoned Halicarnassus, where Memnon, the paramount satrap of Asia Minor, had taken refuge with the Persian fleet, to surrender; and on its refusal took the city and devastated it, but not being able to reduce the citadel, was forced to leave it blockaded. He handed the government back to the family of Mausolus. Later the citizens received the present of a gymnasium from Ptolemy, and built in his honour a stoa or portico; but the city never recovered entirely from the siege, and Cicero describes it as almost deserted. The site is now occupied in part by the town of Budrum; but the ancient walls can still be traced round nearly all their circuit, and the position of several of the temples, the theatre, and other public buildings can be fixed with certainty.

Excavations of the Mausoleum show that the building consisted of five parts—a basement or podium, a pteron or enclosure of columns, a pyramid, a pedestal and a chariot group. The basement was built of greenstone and cased with marble. The pteron consisted (according to Pliny) of thirty-six columns of the Ionic order, enclosing a square *cella*. Between the columns probably stood single statues. From the portions that have been recovered, it appears that the principal frieze of the pteron represented combats of Greeks and Amazons. Above the pteron rose the pyramid, mounting by 24 steps to an apex or pedestal. On this apex stood the chariot with the figure of Mausolus himself and an attendant. The height of the statue of Mausolus in the British Museum is 9 ft. 9½ in. without the plinth. All sorts of restorations of this famous monument have been proposed.

See C. T. Newton and R. P. Pullan, *History of Discoveries at Halicarnassus* (1862-63); J. Fergusson, *The Mausoleum at Halicarnassus restored* (1862); E. Oldfield "The Mausoleum," in *Archaeologia* (1895); F. Adler, *Mausoleum zu Halikarnass* (1900); J. P. Six in *Journ. Hell. Studies* (1905); W. B. Dinsmoor, in *Amer. Journ. of Arch.* (1908); J. J. Stevenson, *A Restoration of the Mausoleum of Halicarnassus* (1909); J. B. K. Preedy, "The Chariot Group of the Mausoleum," in *Journ. Hell. Stud.*, 1910.

HALICZ, a small town of Galicia, Poland, 70 m. by rail S.S.E. of Lwow (Lemberg). It is situated at the confluence of a small stream with the Dniester. In the neighbourhood are the ruins of the old castle, the seat of the ruler of the former kingdom from which Galicia derived its name. Halicz, which is mentioned as early as 1113, was from 1141 to 1255 the residence of the Russian princes of that name. The town as is shown by excavations was then much larger. It probably suffered during the Mongol invasion of 1240. It has changed hands between Poland, Austria and Russia during its history.

HALIDON HILL, BATTLE OF. When the Scottish War was renewed after a four years' uneasy truce, this battle of July 19, 1333, proved the sequel to the unauthorized expedition and battle of Dupplin (*q.v.*) and confirmed the changed balance of fortune. Bruce was dead and the Scots neglected to fulfil his "testament" of guerrilla warfare. Compared with Bannockburn (*q.v.*) the strategical situation was also reversed, for in 1333 Edward III. was besieging Berwick and a great Scottish host marching to relieve it. With him were Baliol and Beaumont, the victors of Dupplin, and there is little doubt that his tactics were inspired by their advice and experience. His force was drawn up in three "battles," composed of dismounted knights and men-at-arms, with archers on the wings. He took up a position like Bruce at Bannockburn—on a hillside with a wood behind and a marshy bottom in front. As the Scottish masses pushed through the marsh and began to climb the slope, they were assailed, and then brought to a standstill, by an unceasing shower of arrows. And when the impetus failed and disorganization spread, Edward ordered his knights to mount and charge, sustaining the pursuit until the Scottish host was a dissolved rabble. The English could well feel that:—

"Scottes out of Berwick and out of Aberdeen,
At the Burn of Bannock ye were far too keen
King Edward has avenged it now, and fully too, I ween."

See Oman, *History of the Art of War in the Middle Ages* (1924).

HALIFAX, CHARLES MONTAGUE, EARL OF (1661-1715), English statesman and poet, fourth son of the Hon. George Montague, was born at Horton, Northamptonshire, on April 16, 1661. He was educated at Westminster school, where he was king's scholar in 1677 and at Trinity college, Cambridge, where he was one of the small band of students who assisted Newton in forming the Philosophical Society of Cambridge. His clever panegyric on the death of Charles II. attracted the notice of the earl of Dorset, who introduced him to the principal wits of the time; and in 1687 his joint authorship with Prior of the *Hind and Panther transversed to the Story of the Country Mouse and the City Mouse*, a parody of Dryden's political poem, helped him to political influence.

In 1689, through Dorset's patronage, he entered parliament as member for Maldon. About this time he married the countess-dowager of Manchester, and after the coronation of William and Mary he purchased a clerkship to the council. His poetical *Epistle occasioned by his Majesty's Victory in Ireland* brought him a pension of £500 per annum. In 1692 he was made one of the commissioners of the treasury. His success as a politician was mainly due to his skill in finance. Although perhaps it was inevitable that England should sooner or later adopt the continental custom of lightening the annual taxation in times of war by contracting a national debt, the actual introduction of the expedient was due to Montague, who on Dec. 15, 1692 proposed to raise a million of money on annuities for 99 years. The Scotsman William Paterson (*q.v.*) had already submitted to the Government his plan of a national bank, and when in the spring of 1694 the prolonged contest with France had rendered another large loan absolutely necessary, Montague introduced the bill for the incorporation of the Bank of England. Immediately after the prorogation of parliament Montague was rewarded by the Chancellorship of the Exchequer.

In 1695 he was returned for Westminster to the new parliament, and pushed through the House his famous Recoinage Bill. To provide for the expense of recoinage, Montague introduced the window tax; the temporary absence of a metallic currency was avoided by the issue for the first time of exchequer bills. He carried (1696) his scheme for the establishment of the Consolidated Fund to meet the interest on government loans, and the rapid restoration of public credit secured him a commanding influence; but although Godolphin resigned office in Oct. 1696, the king hesitated for some time between Montague and Sir Stephen Fox as his successor, and it was not till 1697 that Montague was appointed first lord. In 1697 he was accused by Charles Duncombe (*q.v.*), and in 1698 by a Col. Granville, of fraud, but both charges broke down, and Duncombe was himself incrimi-

nated. In 1698 and 1699 Montague acted as one of the council of regency during the king's absence from England. Unfortunately his vanity and arrogance counterbalanced his administrative ability and his eloquence; and his power was already waning when he conferred the lucrative sinecure office of auditor of the Exchequer on his brother in trust for himself should he be compelled to retire from power. After the return of the king in 1699 he was compelled to resign his offices. He succeeded his brother in the auditorship.

On the accession of the Tories to power he was raised to the peerage (1700) as Lord Halifax. In 1701 he was impeached for malpractices along with Lord Somers and the earls of Portland and Oxford, but all the charges were dismissed by the Lords; and in 1703 a second attempt to impeach him also failed. In 1706 he was one of the commissioners to negotiate the union with Scotland; and after the passing of the Act of Settlement he was sent to the elector's court to convey the insignia of order of the garter to George I. He was a member of the council of regency in 1714 pending the arrival of George I., and was first lord of the treasury in the new ministry. He was also created earl of Halifax and Viscount Sunbury. He died on May 19, 1715 and left no issue. He was buried in the vault of the Albemarle family in Westminster Abbey. His nephew George (d. 1739) succeeded to the barony, and was created Viscount Sunbury and earl of Halifax in 1715.

Montague was a friend to many men of letters. He procured from Godolphin a commissionership for Addison, and enjoyed a life-long intimacy with Newton, for whom he obtained the mastership of the Mint. In administrative talent he surpassed all his contemporaries, and his only rival in parliamentary eloquence was Somers; but the effect of his brilliant financial successes on his reputation was gradually almost nullified by the arrogance of his manner and by his sensitive vanity. Marlborough declared that "he had no other principle but his ambition, so that he would put all in distraction rather than not gain his point."

His *Miscellaneous Works* were published at London in 1704; his *Life and Miscellaneous Works* in 1715; and his *Poetical Works*, to which also his "Life" is attached, in 1716. His poems were reprinted in Johnson's *English Poets*, vol. ix.

HALIFAX, GEORGE MONTAGU DUNK, 2ND EARL OF (1716-1771), son of George Montagu, 1st earl of Halifax (of the second creation), was born on Oct. 5 or 6, becoming earl of Halifax on his father's death in 1739. Educated at Eton and at Trinity college, Cambridge, he became in 1748 president of the Board of Trade. While filling this position he helped to found Halifax, the capital of Nova Scotia, which was named after him, and in several ways he rendered good service to trade, especially with North America. In March 1761 Halifax was appointed lord-lieutenant of Ireland, and he was also for a time first lord of the admiralty. He was from 1762 to 1765 secretary of state for the northern department under Bute and under George Grenville. He signed the general warrant under which Wilkes was arrested in 1763, for which action he was mulcted in damages by the courts of law in 1769, and he was mainly responsible for the exclusion of the name of the king's mother, Augusta, princess of Wales, from the Regency bill of 1765. He returned to office in 1770 under his nephew, Lord North, but died on June 8, 1771.

HALIFAX, GEORGE SAVILE, FIRST MARQUESS OF (1633-1695), English statesman and writer, was the eldest son of Sir William Savile, third baronet, and of Anne, eldest daughter of Lord Keeper Coventry. He sat in the Convention parliament for Pontefract in 1660, and in 1667 he was created Baron Savile of Halifax. A zealous supporter of the Triple Alliance (1668), Halifax was kept in ignorance of the secret terms of the Treaty of Dover (1670), and when he was sent to Holland in 1673 with the mission which visited first The Hague and then Louis XIV.'s headquarters he was unaware of the real state of affairs, and the issue was decided by Arlington. From that time he steadily opposed Charles's policy of subservience to France and the relaxation of the laws against the Roman Catholics. He was dismissed from the council in Jan. 1676, but was reinstated in 1679 and received an earldom.

Halifax pursued a policy apparently devious, which won for him the name of the "Trimmer," but in reality logical. He tried to steer a middle course between the extreme Protestants on the one hand who would go to all lengths, even to the substitution of the duke of Monmouth as heir to the throne, to exclude James, duke of York, and on the other hand the high Tories and the Romanizing policy of James. Thus he opposed the Exclusion bill (1679), speaking 16 times during the debate and materially affecting its issue, but alienated James by approving the Regency bill, and put up a strong opposition to the return of James from Scotland in 1681. In that year he held for a time the chief power, and consistently urged upon Charles a policy of moderation and conciliation. James returned from Scotland in May 1682, and though Halifax was advanced to a marquessate and the office of lord privy seal, his influence at court was gone for the time being. It revived in 1684, when Charles began to tire of James and Rochester. Halifax, who had been in touch with the prince of Orange, tried to establish good relations between him and Charles.

After the accession of James he repeatedly opposed the king's policy and finally, on his firm refusal to support the repeal of the Test and Habeas Corpus Acts, he was dismissed, and his name was struck out of the list of the privy council (Oct. 1685). He corresponded with the prince of Orange, but held aloof from plans which aimed at the prince's personal interference in English affairs. In 1687 he published the famous *Letter to a Dissenter*, in which he warns the Nonconformists against being beguiled by the "indulgence" into joining the court party. The tract, of which 20,000 copies were circulated, actually and immediately altered the course of history. Halifax took the popular side at the trial of the bishops in June 1688; but the same month he refrained from signing the invitation to William, and publicly repudiated any share in the prince's plans. He refused any credence to the report that the prince born to James was supposititious. After the landing of William he was present at the council called by James on Nov. 22, and urged the king to grant large concessions but in friendly terms. With Nottingham and Godolphin he treated with William at Hungerford, but James had from the first resolved on flight. Halifax presided over the council of Lords which concerted measures to maintain public order during the interregnum. On the return of James to London on Nov. 16 Halifax attached himself to William's cause. On Nov. 17, he carried with Lords Delamere and Shrewsbury a message from William to the king advising his departure from London, and, after the king's second flight, directed the executive. On Jan. 22, 1689, he was formally elected speaker of the House of Lords. He voted against the motion for a regency (Jan. 20), which was only defeated by two votes. The moderate and comprehensive character of the settlement at the revolution plainly shows his guiding hand, and he persuaded the Lords to agree to the compromise whereby William and Mary were declared joint sovereigns. On Feb. 13 in the banqueting house at Whitehall, he tendered the crown to them in the name of the nation.

At the opening of the new reign he was made lord privy seal. His views on religious toleration were as wide as those of the new king. He championed the claims of the Nonconformists as against the high or rigid Church party, and he was bitterly disappointed at the miscarriage of the Comprehension bill. He thoroughly approved also at first of William's foreign policy; but, having excited the hostility of both Whig and Tory parties, he was now fiercely attacked, and determined to retire. He still nominally retained his seat in the privy council, but in parliament he became a bitter critic of the administration. He disapproved of William's total absorption in European politics, and his open partiality for his countrymen. In Jan. 1691 Halifax had an interview with Henry Bulkeley, the Jacobite agent, and is said to have promised "to do everything that lay in his power to serve the king." He entered bail for Lord Marlborough, accused wrongfully of complicity in a Jacobite plot in May 1692, and in June, during the absence of the king from England, his name was struck off the privy council. Early in 1695 he delivered a strong attack on the administration in the House of Lords; he died on April 5, at the age of 61. He was buried in Henry VII.'s chapel in West-

minster Abbey.

Halifax's attitude of mind was curiously modern. Reading, writing, and arithmetic, he thinks, should be taught to all and at the expense of the state. His opinions again on the constitutional relations of the colonies to the mother-country were completely opposed to those of his own period. For that view of his character which, while allowing him the merit of a brilliant political theorist denies him the qualities of a man of action and of a practical politician, there is no solid basis. At various times of crisis he proved himself a great leader. He returned to public life to defeat the Exclusion bill. At the revolution it was Halifax who seized the reins of government, flung away by James, and maintained public security. His subsequent failure in collaborating with William was due to his failure to realise the development of party government.

Halifax was by no means the "voluptuary" described by Macaulay. He was on the contrary free from self-indulgence; his manner of life was decent and frugal, and his dress was proverbially simple. Few were insensible to his personal charm and gaiety. He excelled especially in quick repartee. When quite a young man he is described by Evelyn as "a witty gentleman if not a little too prompt and daring." He was incapable of controlling his spirit of raillery, from jests on Siamese missionaries to sarcasms at the expense of the heir to the throne and ridicule of hereditary monarchy, and his brilliant paradoxes, his pungent and often profane epigrams were received by graver persons as his real opinions and as evidences of atheism. This latter charge he repudiated, assuring Burnet that he was "a Christian in submission," but that he could not digest iron like an ostrich nor swallow all that the divines sought to impose upon the world.

The speeches of Halifax have not been preserved, and his political writings on this account have the greater value. In *The Character of a Trimmer* (1684 or 1685), his authorship of which is now established, he discusses the political problems of the time and their solution on broad principles. When he treats such themes as liberty, or discusses the balance to be maintained between freedom and government in the constitution, he rises to the political idealism of Bolingbroke and Burke. His other political writings are: *The Character of King Charles II.* (printed 1750); *Letter to a Dissenter* (1687); *The Lady's New Year's Gift, or Advice to a Daughter* (1688); *The Anatomy of an Equivalent* (1688); *Maxims of State* (c. 1692); *The Rough Draft of a New Model at Sea* (c. 1694); *Some Cautions to the electors of the parliament* (1694); and *Political, Moral and Miscellaneous Thoughts and Reflections* (n.d.). (For other writings attributed to Halifax, see Foxcroft, *Life of Sir G. Savile*, ii. 529, sqq.)

Halifax was twice married, in 1656 to Lady Dorothy Spencer—daughter of the first earl of Sunderland and of Dorothy Sidney, "Sacharissa"—who died in 1670, leaving a family; and secondly in 1672 to Gertrude Pierrepont, who survived him, and by whom he had one daughter, Elizabeth, Lady Chesterfield. On the death of his son William, second marquess of Halifax, in Aug. 1700 without male issue, the peerage became extinct and the baronetcy passed to the Saviles of Lupset, the whole male line of the Savile family ending in the person of Sir George Savile, eighth baronet, in 1784. Henry Savile, British envoy at Versailles, who died unmarried in 1687, was a younger brother of the first marquess. Halifax has been generally supposed to have been the father of the illegitimate Henry Carey, the poet, but this is doubtful.

See H. S. Foxcroft, *Life and Letters of Sir George Savile, 1st Marquis of Halifax* (2 vols., 1898).

HALIFAX, a city and port of entry, capital of the province of Nova Scotia, Canada. It is situated in 44° 59' N. and 63° 35' W., on the south-east coast of the province, on a fortified hill, 225 ft. in height, which slopes down to the waters of Chebucto bay, now known as Halifax harbour. The harbour, which is open all the year, is about 6 m. long by 1 m. in width, and has excellent anchorage in all parts; to the north a narrow passage connects it with Bedford basin, 6 m. in length by 4 m., and deep enough for the largest men-of-war. At the harbour mouth lies McNab's island, thus forming two entrances; the eastern passage is only employed by small vessels. The population in 1921 was 58,372.

Inferior in natural strength to Quebec alone, the city and its approaches have been fortified till it has become the strongest position in Canada, and one of the strongest in the British empire. Till 1906 it was garrisoned by British troops, but in that year, with Esquimalt, on the Pacific coast, it was taken over by the Canadian government, an operation necessitating a large increase in the Canadian permanent military force. At the same time, the royal dockyard, containing a dry-dock 610 ft. in length, and the residences in connection, were also taken over for the use of the department of marine and fisheries. Till 1905 Halifax was the summer station of the British North American squadron. In that year, in consequence of a redistribution of the fleet, the permanent North American squadron was withdrawn; but Halifax is still visited periodically by powerful squadrons of cruisers.

Though, owing to the growth of Sydney and other outports, it no longer monopolizes the foreign trade of the province, Halifax is still a thriving town, and has the largest export trade of the Dominion in fish and fish products. Lumber (chiefly spruce deals) and agricultural products (especially apples) are also exported in large quantities. The chief imports are manufactures from Great Britain and the United States, and sugar, molasses, rum and fruit from the West Indies. Its industrial establishments include foundries, sugar refineries, manufactures of furniture and other articles of wood, a skate factory and rope and cordage works, the produce of which are all exported. It is the Atlantic terminus of the Canadian National and Dominion Atlantic railways, and the chief winter port of Canada, numerous steamship lines connecting it with Great Britain, Europe, the West Indies and the United States. The educational institutions include a ladies' college, several convents, a Presbyterian theological college and Dalhousie university, with faculties of arts, law, medicine and science. Other prominent buildings are Government house, the provincial parliament and library, and the Roman Catholic cathedral. St. Paul's church (Anglican) dates from 1750, and though not striking architecturally, is interesting from the memorial tablets and the graves of celebrated Nova Scotians which it contains. The city is the seat of the Anglican bishop of Nova Scotia and Prince Edward island, and of the Roman Catholic bishop of Halifax. About one tenth of the city area was devastated in 1917 by the explosion of a French steamer carrying 3,000 tons of T.N.T., on colliding with a Norwegian steamer on its way with a relief cargo to Belgium. Reconstruction has been carried out on modern lines of town planning.

Founded in 1749 by the Hon. Edward Cornwallis as a rival to the French town of Louisburg in Cape Breton, it was named after the 2nd earl of Halifax, president of the board of trade and plantations. Its privateers played a prominent part in the war of 1812-15 with the United States, and during the American Civil War it was a favourite base of operations for Confederate blockade-runners.

HALIFAX, a municipal county and parliamentary borough in the West Riding of Yorkshire, England, 194 m. N.N.W. from London and 7 m. S.W. from Bradford, on the L.N.E. and L.M.S. railways. Pop. (1921), 99,127. It lies in a bare hilly district on the Hebble, near its confluence with the Calder. The left bank of the Hebble is steep, allowing only small urban development, and the main part of the town is situated on the slopes of an eastward facing spur, on the right bank of the stream. Bridges carrying both road and rail span the valley, the most important being the North bridge, a fine iron structure.

The general appearance of the town is modern—a development of the industrial period—though a few old houses remain. Two early churches are traceable, the first may be pre-Norman, the second of the Early English period, with some very fine woodwork, the greater portion of which dates from 1621. The parish church of St. John the Baptist is Perpendicular, with a lofty western tower. All Souls' church was built in 1859, from the designs of Sir Gilbert Scott. The Square chapel, erected by the Congregationalists in 1857, is a striking building. Among public buildings are the Palladian town hall, with a tower completed in 1863, after the designs of Sir Charles Barry, the central library and museum, and the Akroyd museum and art gallery. The Heath Grammar school was founded in 1585 under royal charter for instruction in

classical languages. It possesses close scholarships at Oxford and Cambridge universities. The Piece Hall was erected in 1799 for the lodgment and sale of piece goods; it is now used as a market. There are six parks.

Halifax ranks with Bradford and Huddersfield as a seat of the woollen and worsted industries. The manufacture of carpets is important, one establishment employing some 5,000 hands. Cotton is also manufactured, and iron and steel industries, resulting in the manufacture of machinery, are very extensive. Coal and freestone are found in the neighbourhood.

History.—At the time of the Conquest, Halifax formed part of the extensive royal manor of Wakefield, but in the 13th century it was in the hands of John, Earl Warrenne (c. 1245–1305). The cloth trade began in the 15th century, when there are said to have been only 13 houses. Before the end of the 16th century this number had increased to 520. Camden, about the end of the 17th century, wrote that “the people are very industrious, so that though the soil about it be barren and unprofitable, not fit to live on, they have so flourished . . . by the clothing trade that they are very rich and have gained a reputation for it above their neighbours.” The trade is said to have been increased by the arrival of certain merchants driven from the Netherlands by the persecution of the duke of Alva. Among the curious customs of Halifax was the Gibbet law, which was probably established by a prescriptive right to protect the wool trade. It gave the inhabitants the power of executing anyone taken within their liberty, who, when tried by a jury of 16 of the frith-burgesses, was found guilty of the theft of any goods of the value of more than 13 pence. The executions took place on market days, on a hill outside the town, the last execution taking place in 1650.

In 1607, David Waterhouse, lord of the manor of Halifax, obtained a grant of two markets there every week, on Friday and Saturday, and two fairs every year, each lasting three days, one beginning on June 24, the other on Nov. 11. Later, an extra market was added, on Thursday. The market rights were sold to the Markets company in 1810, and purchased from them by the corporation in 1853. In 1635 the king granted the inhabitants of Halifax a licence to found a workhouse, and incorporated them under the name of the master and governors. A large house was given them for the purpose by Nathaniel Waterhouse, who was appointed the first master, his successors being elected every year by the 12 governors from among themselves. During the Civil War, Halifax was garrisoned by the parliament, and a field near it is still called the Bloody Field, on account of an engagement which took place there.

Halifax was a borough by prescription, its privileges increasing with increased prosperity brought by the cloth trade, but it was not incorporated until 1848. After the Reform Act of 1832 the burgesses have returned two members to parliament; the borough now returns one. The county borough was created in 1888.

HALISAH (Heb. “act of untying *sc.* the shoe”), act of testimony to the refusal of a man to marry the widow of his brother who has left no son (or child according to Sadducean views, *cf.* Mark xii. 19 and possibly Josephus *Ant.* iv. 8, 23). The word is better written *Halīqah*. The biblical sources for this marriage (levirate, *q.v.*) are Deut. xxv. 5–10 and Gen. xxxviii. 8. This primitive custom was designed to safeguard the widow and the estate. In the days of polygamy, refusal was looked upon as selfishness (*cf.* Ruth iii. 13; iv. 1–12) and the biblical procedure was intended to shame one guilty of unbrotherly conduct. With the passing of polygamy—and no instance occurs in the Talmud of a Rabbi with more than one wife—the levirate marriage became impossible. Consequently, in course of time both the marriage and the repudiation were regarded as disastrous and every legal effort was made to avoid their necessity: a valid reason for remitting *Halīqah* was always accepted and ingenuity was displayed in finding reasons. Marriage between uncle and niece was deprecated in case the husband died and the widow's father should have to undergo the renunciation ceremony. To prevent extortion on the part of brothers-in-law, brothers were often required to sign a document at their sister's marriage, pledging themselves not to refuse *Halīqah* if the need arose and not to exact payment

for compliance. Full details with illustrations will be found in the *Jewish Encyclopedia*, *s.v.* Halizah Levirate.

HALKETT, HUGH, FREIHERR VON (1783–1863), British soldier and general of infantry in the Hanoverian service, was the second son of Major-General F. G. Halkett, and served in India from 1798 to 1801, in Cathcart's expeditions to Hanover, Rügen and Copenhagen, in the Peninsula in 1808–1809, at Walcheren, and then again in Spain. He was subsequently employed in the organization of the new Hanoverian army. In the Waterloo campaign he commanded two brigades of Hanoverian militia which were sent to the front with the regulars. After the fall of Napoleon he elected to stay in the Hanoverian service, and rose to be general and inspector-general of infantry. In his old age he led the X. Federal Army Corps in the Danish War of 1848, and defeated the Danes at Oversee.

See Knesebeck, *Leben des Freiherrn Hugh von Halkett* (Stuttgart, 1865).

His brother, SIR COLIN HALKETT (1774–1856), British soldier, began his military career in the Dutch Guards but entered the British service, served through the Peninsular War, and commanded in 1815 the 5th British Brigade of Alten's division. At Waterloo he received four wounds. Unlike his brother, he remained in the British service, in which he rose to general. At the time of his death he was governor of Chelsea hospital.

For information about both the Halketts, see Beamish, *History of the King's German Legion* (1832).

HALL, ASAPH (1829–1907), American astronomer, was born on Oct. 15, 1829, at Goshen, Conn., and left school when 13 years of age to support the family after the death of his father. At 16 he became a carpenter and his desire to be an architect led him to study mathematics. Nine years later he was able to spend a year and a half at Central college, McGrawville, N.Y., and later a summer term at the University of Michigan, where, under Brünnow, he made his first acquaintance with astronomical instruments. Determined to become an astronomer, he went to Cambridge, Mass., in 1857, as an assistant to Prof. Bond at \$3 a week. In 1862 he had made such progress that he was appointed an aid, and one year later professor in mathematics at the U.S. Naval Observatory, Washington, D.C. This position he held until his retirement in 1891. From 1895 to 1901 he was professor of astronomy at Harvard. At the Naval observatory Hall had the 26 in. equatorial telescope under his charge from 1875 to 1891. His work with it was chiefly in three fields; planetary observations and the orbits of their satellites; observations of double-star orbits; determinations of the stellar parallax. In each of these fields Hall's extensive observations were of great value. His most spectacular achievement was the discovery in 1877 of the two satellites of Mars, whose orbits he calculated. He died at Annapolis, Md., on Nov. 22, 1907.

See G. W. Hill, *Biographical Memoir of Asaph Hall* (1908) which contains a full bibliography of Hall's scientific writings, and A. Hall, *An Astronomer's Wife* (1908), a biography of Mrs. Hall.

HALL, BASIL (1788–1844), British naval officer and traveler, was born at Edinburgh on Dec. 31, 1788, the son of Sir James Hall of Dunglass, the geologist. Basil entered the navy in 1802, and in 1817 became post-captain. His cruise in the sloop “Lyra” in 1816 with Lord Amherst's embassy, to China is described in *An Account of a Voyage of Discovery to the West Coast of Corea and the Great Loochoo Island in the Japan Sea* (1818). In 1824 he published *Extracts from a Journal written on the Coasts of Chili, Peru and Mexico, in the Years 1820–21–22*, and in 1829 *Travels in North America in the Years 1827 and 1828*. His *Fragments of Voyages and Travels* (9 vols.) appeared in three detachments between 1831 and 1840. He died in Haslar hospital, Portsmouth, on Sept. 11, 1844.

HALL, CARL CHRISTIAN (1812–1888), Danish statesman, was born at Christianshavn on Feb. 25, 1812, and was educated for the law. Returned to the *Rigsforsamling* of 1848 as member for the first district of Copenhagen, which he continued to represent in the *Folketing* till 1881, he displayed rare ability as a debater, while his extraordinary tact and temper disarmed opposition. Hall was not altogether satisfied with the fundamental

law of June: but he accepted the existing constitution and sought to unite the best conservative elements of the nation in its defence. Failing to rally the landed aristocracy to the good cause, he determined to organize the middle class into a political party. Hence the "June Union," whose programme was progress and reform in the spirit of the constitution, and at the same time opposition to the *Bondevenner* or peasant party. The "Union" exercised an essential influence on the elections of 1852, and was, in fact, the beginning of the national Liberal party, which found its natural leader in Hall. During the years 1852-54 the burning question of the day was the connection between the various parts of the monarchy. Hall was "eiderdansk" by conviction. He saw in the closest possible union between the kingdom and a Slesvig freed from all risk of German interference the essential condition for Denmark's independence; but he did not think that Denmark was strong enough to carry such a policy through unsupported, and he was therefore inclined to promote it by diplomatic means and international combinations.

Hall first took office in the Bang administration (Dec. 12, 1854) as minister of public worship. In May 1857 he became president of the council after Andrae, Bang's successor, had retired, and in July 1858 he exchanged the ministry of public worship for the ministry of foreign affairs, while still retaining the premiership. Hall's programme, "den Konstitutionelle Helstat," i.e., a single State with a common constitution, was difficult enough in a monarchy which included two nationalities, one of which, to a great extent, belonged to a foreign and hostile jurisdiction. But as this situation had been guaranteed by the Conventions of 1851-52, Hall sought to establish this "Helstat" by the Constitution of Nov. 13, 1863. For the failure of the attempt see DENMARK: History. Hall himself soon became aware of the impossibility of the "Helstat," and his whole policy aimed at making its absurdity patent to Europe, and substituting for it a constitutional Denmark to the Eider which would be in a position to come to terms with an independent Holstein. That this was the best thing possible for Denmark is indisputable, and "the diplomatic Seven Years' War," which Hall in the meantime conducted with all the powers interested in the question, is the most striking proof of his superior statesmanship.

After 1864 Hall's unconquerable faith in the future of his country made him, during those difficult years, a power in the public life of Denmark. In 1870 he joined the Holstein-Holsteinborg ministry as minister of public worship; he passed many useful educational reforms, but on the fall of the administration, in 1873, he retired from public life. He died on Aug. 14, 1888.

See V. C. S. Topsøe, *Polit. Portrætsstudier* (Copenhagen, 1878); S. P. V. Birkedal, *Personlige Oplevelser* (Copenhagen, 1890-91).

HALL, CHARLES FRANCIS (1821-1871), American arctic explorer, was born at Rochester, N.H. His enthusiasm for arctic exploration led him in 1859 to volunteer to the American Geographical Society to "go in search for the bones of Franklin." With the proceeds of a public subscription he was equipped for his expedition and sailed in May 1860 on board a whaling vessel. The whaler being ice-bound, Hall took up his abode in the regions to the north of Hudson bay, where he found relics of Frobisher's 16th century voyages. He published an account of his experiences under the title of *Arctic Researches and Life among the Esquimaux* (1864). Determined to learn more about the fate of the Franklin expedition he returned to the same regions in 1864, and passing five years among the Eskimo was successful in obtaining a number of Franklin relics, as well as information pointing to the exact fate of 76 of the crew, whilst also performing some geographical work of interest. In 1871 he was given command of the North Polar expedition fitted out by the U.S. Government in the "Polaris." Making a remarkably rapid passage up Smith sound at the head of Baffin bay, which was found to be ice-free, the "Polaris" reached on Aug. 30, the lat. of 82° 11', at that time and until the English expedition of 1876 the highest north attained by vessel. He died suddenly on Nov. 8, 1871.

HALL, CHARLES MARTIN (1863-1914), American inventor, was born at Thompson, O., on Dec. 6, 1863, and graduated at Oberlin college in 1885. While still at college he became in-

terested in the problem of devising a cheap process for the reduction of aluminium. Working with such apparatus as the Oberlin laboratory afforded, he invented, eight months after his graduation, the electrolytic process, which forms the basis for the present commercial production of the metal. The next three years were spent perfecting his process and interesting capitalists. In 1889 the Pittsburgh Reduction Company (later the Aluminum Company of America) began to manufacture aluminium and in 1890 Hall was made its vice-president. The invention made aluminium a common article of commerce, for which constantly increasing uses are being found. Hall's death occurred in Daytona, Fla., on Dec. 27, 1914. The fortune resulting from his invention was bequeathed chiefly to educational institutions, Oberlin receiving gifts totalling more than \$3,000,000.

HALL, CHRISTOPHER NEWMAN (1816-1902), English Nonconformist divine, was born at Maidstone on May 22, 1816. He was educated at University college, London, and at Highbury college, and was then appointed pastor of the Albion Congregational Church, Hull. At Hull Newman Hall first began his active work in temperance reform, and in defence of his position wrote *The Scriptural Claims of Teetotalism*. In 1854 he became pastor of Surrey chapel, London, which was superseded by Christchurch, Westminster Bridge Road, for the building of which Newman Hall raised the money. He held his charge for nearly 40 years, resigning in 1892 to devote himself to general evangelical work. Newman Hall visited the United States during the Civil War, and did much to promote a friendly understanding between England and America. A Liberal in politics, and a keen admirer of John Bright, few preachers of any denomination have exercised so far-reaching an influence as the "Dissenters' Bishop," as he came to be termed. He died on Feb. 18, 1902.

See his *Autobiography* (1898).

HALL, EDWARD (c. 1498-1547), English chronicler and lawyer, was a son of John Hall of Northall, Shropshire. Educated at Eton and King's college, Cambridge, he became common serjeant of the city of London and judge of the sheriff's court. He was also M.P. for Bridgnorth. Hall's great work, *The Union of the Noble and Illustre Famelies of Lancastre and York*, commonly called *Hall's Chronicle*, was first published in 1542, and continued by Richard Grafton (q.v.). The value of the *Chronicle* in its early stages is not great, but is very considerable for the reign of Henry VIII. To the student of literature it has the exceptional interest of being one of the prime sources of Shakespeare's historical plays.

See J. Gairdner, *Early Chroniclers of Europe; England* (1879), and the editions of the *Chronicle* by Sir H. Ellis (1809) and C. Whitley (1904).

HALL, FITZEDWARD (1825-1901), American orientalist, was born in Troy, N.Y., on March 21, 1825. He graduated at the Rensselaer Polytechnic institute at Troy in 1842, and entered Harvard in the class of 1846; just before his class graduated he went to India in search of a runaway brother. In Jan. 1850 he was appointed tutor, and in 1853 professor of Sanskrit and English, in the Government college at Benares; in 1855 he was made inspector of public instruction in Ajmere-Merwara and in 1856 in the Central Provinces. He settled in England in 1862 and received the appointment to the chair of Sanskrit, Hindustani and Indian jurisprudence in King's college, London, and to the librarianship of the India Office. He died at Marlesford, Suffolk, on Feb. 1, 1901.

Hall ed. and trans. in the *Bibliotheca Indica*, many oriental works, including *A'tma-bodha* (1852), *Sāṅkhya-pravachana-bhāṣya* (1856), *Vāsavadattā* (1855-59) and the *Dāsa-rūpa* (1865). He also was the author of *A Contribution towards an Index to the Bibliography of the Indian Philosophical Systems* (1859), text-books, and several works on English philology. His valuable collection of oriental mss. he gave to Harvard university.

HALL, GRANVILLE STANLEY (1844-1924), American psychologist and educationalist, was born at Ashfield, Mass., on Feb. 1, 1844, of Puritan ancestry. He graduated from Williams college in 1867, studied in Germany two years, and graduated from Union Theological seminary in 1871. After holding the chair of psychology at Antioch college, 1872-76, he studied under

William James at Harvard and took the degree of Ph.D. in 1878. He then pursued for two years further studies at Berlin, Bonn, Heidelberg and Leipzig, working with Wundt, Helmholtz and other noted investigators. From 1881 to 1888 Hall was professor of psychology at Johns Hopkins university, where his laboratory was the first of its kind in the country, and attracted many able students, among them John Dewey, Joseph Jastrow and J. McKeen Cattell. In 1889 Hall was installed first president and made professor of psychology of the newly formed Clark university, Worcester, Mass., which, under his personal leadership, was devoted, during its first two decades, chiefly to educational research. Because of his varied and interesting investigations, he attained prominence in the educational field, and for thirty years was an important contributor to educational literature. He became widely known as an exponent of the culture-epoch theory, a doctrine set forth in his most influential work, *Adolescence* (1904). Although his methods at times lacked in scientific precision, his contributions to the progress of psychology and education in his time were substantial and stimulating. In 1887 he founded the *American Journal of Psychology*, which he edited until 1921. For long periods he edited also several other scientific and educational journals. He resigned the presidency of Clark university in 1920, but continued active literary work until his death, April 24, 1924.

Hall's numerous published works include: *The Contents of Children's Minds on Entering School* (1894), *Youth—Its Education, Regimen and Hygiene* (1907), *Educational Problems* (1911), *Founders of Modern Psychology* (1912), *Jesus the Christ, in the Light of Psychology* (1917), *Morale: The Supreme Standard of Life and Conduct* (1920), *Recreations of a Psychologist* (1920), *Senescence* (1922), and *Life and Confessions of a Psychologist* (1923).

See G. E. Partridge, *Genetic Philosophy of Education: An Epitome of the Published Writings of G. Stanley Hall* (1912); Louis N. Wilson, *G. Stanley Hall: A Sketch* (1914); and Lorine Pruett, *G. Stanley Hall; a Biography of Mind* (1926).

HALL, ISAAC HOLLISTER (1837-1896), American Orientalist, was born in Norwalk, Connecticut, on December 12, 1837. He graduated at Hamilton College in 1859, was a tutor there in 1859-1863, graduated at the Columbia Law School in 1865, practised law in New York City until 1875 and in 1875-1877 taught in the Syrian Protestant College at Beirut where he discovered a valuable Syriac manuscript of the Philoxenian version of a large part of the New Testament which he published in part in facsimile in 1884. He worked with General di Cesnola in classifying the famous Cypriote collection in the Metropolitan Museum of New York City and was a curator of that museum from 1885 until his death in Mount Vernon, New York, on July 2, 1896.

HALL, SIR JAMES (1761-1832), Scottish geologist and physicist, was born at Dunglass on Jan. 17, 1761. He made a series of experiments to demonstrate the views of James Hutton with regard to intrusive rocks, and was thus the founder of experimental geology. The results of his experiments were brought before the Royal Society of Edinburgh. He was M.P. for Michael, Cornwall, from 1807-12. He died on June 23, 1832, at Edinburgh. He left three sons, of whom the second, Basil (q.v.), was a well known writer of travel books.

HALL, JAMES (1793-1868), American judge and man of letters, was born Aug. 19, 1793. Perhaps the most zealous worker for adequate treatment of the early West in literature, Hall was nevertheless not a native of this section. He was born in Philadelphia, studied law in the East and took a gallant part in the War of 1812 before migrating to the Mississippi Valley "in search of adventure." After being admitted to the bar in Pittsburgh he commenced practice at Shawneetown (Ill.), where he also edited the *Illinois Gazette*. Successively public prosecutor of the circuit, circuit judge, and state treasurer (1827-31), he nevertheless continued his practice and did much editorial work. He died near Cincinnati, July 4, 1868.

Hall is at his best in the short stories contained in *The Soldier's Bride* (1833), *Tales of the Border* (1835), *Legends of the West* (1832), and *The Wilderness and the War-Path* (1846). In parts these are marred by melodrama, but his tales of the tiny French villages show a delicate humour, an imaginative charm

and an ease and grace of style that reveal Hall as a follower of Irving and a significant figure in the development of the American short story.

See W. H. Venable, "Judge James Hall" in *Beginnings of Literary Culture in the Ohio Valley* (1891), and F. L. Pattee, *The Development of the American Short Story* (1923).

HALL, JAMES (1811-1898), American geologist and palaeontologist, was born at Hingham, Mass., on Sept. 12, 1811. Extreme poverty was the lot of his family, and he acquired through his own efforts his early education, which was, however, sufficiently complete to prepare him for admission to the Rensselaer Polytechnic Institute of Troy, New York. Even as a boy he was passionately interested in natural history, and at the time of Silliman's Lowell lectures he walked to Boston and back from Hingham in order to attend them. As a student he collected and determined more than 900 species of plants. He spent his summers and all of his limited finances doing field work. After his graduation from the Rensselaer institute in 1832 he became librarian at the institute, and later in the same year an assistant professor; subsequently he became professor of chemistry, natural science and geology. Stephen Van Rensselaer became interested in Hall and sent him to make geological explorations in the St. Lawrence valley.

In 1836 he was appointed one of four geologists on the geological survey of the State of New York which had been established just before that time. Although the youngest of the group, his is the only one of the four final reports which deals broadly with the problems of the science and has endured with authority as a classic of geological literature.

Eventually Hall became State geologist and director of the Museum of Natural History of Albany. Through various periods when State support was withdrawn from geological work, he carried it on at his own expense. At one time he sold 2,000 ac. of Ohio land in order to gain funds to pay obligations incurred through his work, receiving \$15,000 for the land, which was valued at \$200,000 ten years later. It was only through this sacrifice that the continued publication of the volume of the *Palaeontology of New York* (1847-94) was made possible. These volumes, the results of his chief work, contained descriptions of the invertebrate fossils of New York, in which he dealt with the graptolites, brachiopods, mollusca, trilobites, echini and crinoids of the palaeozoic formations. He was also at one time State geologist of Iowa and afterwards of Wisconsin.

His publications, dating from 1836, include more than 260 scientific papers and 35 books, dealing with numerous phases of geology and palaeontology of the different regions of the United States and Canada, including reports on the geology of Oregon and California (1845), of Utah (1852), Iowa (1859) and Wisconsin (1862). He received the Wollaston medal from the Geological Society of London in 1858.

Hall was regarded as a great teacher as well as collector. In his 86th year he journeyed to St. Petersburg (Leningrad) to take part in the International Geological Congress, and then joined the excursion to the Ural mountains. He died at Echo Hill, Bethlehem, New Hampshire, on Aug. 7, 1898, and was buried at Albany.

His most important publications were: *Palaeontology of New York*, vols. 1-8 (1847-88; vol. 8, in collaboration with J. M. Clarke, of especial importance); *Geology of New York*, part IV. (comprising the survey of the fourth geological district, 1843); with J. M. Clarke *An Introduction to the Study of the Brachiopoda*, part I. (11th annual report of New York State Geologist, 1892); and part II. (13th annual report, 1894). A complete bibliography of his work is given in the *Bulletin of the Geological Society of America*, vol. X. (1898), pp. 436-451. See also "Life and Works of James Hall," by H. C. Hovey, *American Geol.* XXIII. (1899), p. 137 (portraits); "Memoir of James Hall," by John J. Stevenson, *Bull. of Geol. Soc. of America*, vol. X. (1898), pp. 425-435.

HALL, JOSEPH (1574-1656), English bishop and satirist, was born at Bristow park, near Ashby de la Zouch, Leicestershire, on July 1, 1574. He was sent (1589) to Emmanuel college, Cambridge, where he wrote his *Virgideumiarum* (1597), satires written after Latin models. The claim he put forward in the prologue to be the earliest English satirist:—

I first adventure, follow me who list
And be the second English satirist—

gave bitter offence to John Marston, who attacks him in the satires published in 1598. He was presented (1601) by Sir Robert Drury to the living of Halsted, Essex. His devotional writings had attracted the notice of Henry, prince of Wales, who made him one of his chaplains (1608); other preferments followed. In 1616 the king nominated him dean of Worcester, and in 1617 he accompanied James to Scotland, where he defended the five points of ceremonial which the king desired to impose upon the Scots. In the next year he was one of the English deputies at the synod of Dort. In 1624 he refused the see of Gloucester, but in 1627 became bishop of Exeter.

He took an active part in the Arminian and Calvinist controversy in the English Church. He did his best in his *Via media*, *The Way of Peace*, to secure a compromise. In spite of his Calvinistic opinions he maintained that to acknowledge the errors which had arisen in the Catholic Church did not necessarily imply disbelief in her catholicity, and that the Church of England having repudiated these errors should not deny the claims of the Roman Catholic Church on that account. This view commended itself to Charles I. and his episcopal advisers, but Laud sent spies into Hall's diocese to report on the Calvinistic tendencies of the bishop and his lenience to the Puritan and low-church clergy. His defence of the English Church, entitled *Episcopacy by Divine Right* (1640), was twice revised at Laud's dictation. This was followed by *An Humble Remonstrance to the High Court of Parliament* (1640 and 1641), an eloquent and forceful defence of his order, which produced a retort from the syndicate of Puritan divines, who wrote under the name of "Smectymnus," and was followed by a long controversy to which Milton contributed five pamphlets, virulently attacking Hall and his early satires.

In 1641 Hall was translated to the see of Norwich, and in the same year sat on the Lords' Committee on religion. On Dec. 30 he was, with other bishops, brought before the bar of the House of Lords to answer a charge of high treason of which the Commons had voted them guilty. They were finally convicted of an offence against the Statute of Praemunire, and condemned to forfeit their estates, receiving a small maintenance from the parliament. They were immured in the Tower from New Year to Whitsuntide. On his release Hall went to his new diocese at Norwich, the revenues of which he seems for a time to have received, but in 1643, when the property of the "malignants" was sequestrated, Hall had difficulty in securing the maintenance (£400) assigned to the bishop by the parliament and was compelled to retire to Higham, near Norwich, where he spent the time preaching and writing until "he was first forbidden by man, and at last disabled by God." He died on Sept. 8, 1656. Thomas Fuller says: "He was commonly called our English Seneca, for the purenesse, plainnesse and fulnesse of his style. Not unhappy at *Controversies*, more happy at *Comments*, very good in his *Characters*, better in his *Sermons*, best of all in his *Meditations*."

It is by his early work as the censor of morals and the unsparing critic of contemporary literary extravagance and affectations that Hall is best known. *Virgidemiarum. Sixe Bookes. First three Bookes. Of Toothlesse Satyrs.* (1) *Poeticall*, (2) *Academicall*, (3) *Morall* (1597) was followed by an amended edition in 1598, and in the same year by *Virgidemiarum. The three last bookes. Of byting Satyres* (reprinted 1599). If he was not the earliest English satirist, Hall was certainly one of the best. He writes in the heroic couplet, which he manoeuvres with great ease and smoothness. In the first book of his satires (*Poeticall*) he attacks the writers whose verses were devoted to licentious subjects, the bombast of *Tamburlaine* and other tragedies, the laments of the ghosts of the *Mirror for Magistrates*, the metrical eccentricities of Gabriel Harvey and Richard Stanyhurst, the extravagances of the sonneteers, and the sacred poets. In Book II. Satire 6 occurs the well-known description of the trencher-chaplain, who is tutor and hanger-on in a country manor. Book VI. consists of one long satire on the various vices and follies dealt with in the earlier books. If his prose is sometimes antithetical and obscure, his

verse is remarkably free from the quips and conceits which mar so much contemporary poetry.

He also wrote *The King's Prophecie; or Weeping Joy* (1603), a gratulatory poem on the accession of James I.; *Epistles*, both the first and second volumes of which appeared in 1608 and a third in 1611; *Characters of Virtues and Vices* (1608), versified by Nahum Tate (1691); *Solomons Divine Arts . . .* (1609); and, probably, *Mundus alter et idem sive Terra Australis antehac semper incognita . . . lustrata* (1605? and 1607), by "Mercurius Britannicus." *Mundus alter* is an excuse for a satirical description of London, and is said to have furnished Swift with hints for *Gulliver's Travels*. For the arguments in favour of the authorship by Alberico Gentili, see E. A. Petherick, *Mundus alter et idem*, reprinted from the *Gentleman's Magazine* (July 1896). His controversial writings include:—*A Common Apology . . . against the Brownists* (1610); *Episcopacie by Divine Right* (1640); *A Short Answer to the Vindication of Smectymnus* (1641); *A Modest Confutation of . . . (Milton's) Animadversions* (1642).

His devotional works include: *Heaven upon Earth, or of True Peace and Tranquillitie of Mind* (1606), reprinted in John Wesley's *Christian Library* (1819); *The Devout Soul* (1644), often since reprinted; *Christ Mystically* (1647), of which General Gordon was a student, and others.

BIBLIOGRAPHY.—The chief authority for Hall's biography is to be found in his autobiographical tracts: *Observations of some Specialities of Divine Providence in the Life of Joseph Hall, Bishop of Norwich, Written with his own hand*; and his *Hard Measure*, reprinted in Christopher Wordsworth's *Ecclesiastical Biography*. The best criticism of his satires is to be found in Thomas Warton's *History of English Poetry*, vol. iv. pp. 363-409 (ed. Hazlitt, 1871). Editions of Hall's works appeared in 1625, 1627, 1628, 1634, 1662. The first complete *Works* appeared in 1808, ed. by the Rev. Josiah Pratt. See also A. B. Grosart, *The Complete Poems of Joseph Hall . . . with introductions, etc.* (1879); *Satires, etc.* (*Early English Poets*, ed. S. W. Singer, 1824).

HALL, MARSHALL (1790-1857), English physiologist, was born on Feb. 18, 1790, at Basford, near Nottingham, the son of a cotton manufacturer. He studied medicine at Edinburgh, and became resident house physician to the Royal Infirmary. This appointment he resigned after two years to visit the medical schools of Paris, Berlin and Göttingen. He then settled at Nottingham, where he became physician to the General Hospital, and in 1826 removed to London. Hall's principal works are: *Diagnosis* (1817); *Mimoses* (1818), on the affections designated as bilious, nervous, etc.; *Observations on Blood-letting* (1830), and *Experimental Essay on the Circulation of the Blood in the Capillary Vessels* (1831) in which he showed that the blood-channels intermediate between arteries and veins serve the office of bringing the fluid blood into contact with the material tissues of the system. In 1832 he read before the Royal Society a paper "On the inverse ratio which subsists between respiration and irritability in the animal kingdom." His most important work in physiology was concerned with the theory of reflex action, embodied in a paper "On the reflex function of the Medulla Ob-longata and the Medulla Spinalis" (1832), supplemented in 1837 by another "On the true Spinal Marrow, and the Excito-motor System of Nerves." Hall thus became the authority on the multiform deranged states of health referable to an abnormal condition of the nervous system. His "ready method" for resuscitation in drowning and other forms of suspended respiration has saved innumerable lives. He died on Aug. 11, 1857.

A list of his works and details of his "ready method," etc., are given in his *Memoirs* by his widow (1861).

HALL, ROBERT (1764-1831), English Baptist divine, was born on May 2, 1764, at Arnesby near Leicester, where his father, Robert Hall (1728-1791), was pastor of a Baptist congregation. Ending his studies at Aberdeen university he became classical tutor at the Bristol academy, where he spent four years. In 1790 he became pastor of a church at Cambridge, where he remained for 15 years and made a great reputation as a preacher. He died on Feb. 21, 1831.

See *Works of Robert Hall, A.M., with a Brief Memoir of his Life*, by Olinthus Gregory, LL.D., and *Observations on his Character as Preacher* by John Foster (6 vols. 1832).

HALL, SAMUEL CARTER (1800–1889), English journalist, was born at Waterford, the son of an army officer. In 1839 he founded and edited *The Art Journal* in which he exposed the trade in bogus "Old Masters." His wife, Anna Maria Fielding (1800–81), became well known as Mrs. S. C. Hall, for her numerous novels, sketches of Irish life, and plays.

HALL, WILLIAM EDWARD (1835–94), English writer on international law, was born on Aug. 22, 1835, at Leatherhead, Surrey. His father was physician to the king of Hanover, and subsequently to the British legation at Naples, and the boy spent much of his early life abroad. After a distinguished career at Oxford university, he was called to the bar at Lincoln's Inn in 1861. He spent much of his time in travel. He was an early and enthusiastic member of the Alpine club, making several first ascents, notably that of the Lyskamm. His travels took him to Lapland, Egypt, South America and India. In 1874 he published a thin 8vo upon the *Rights and Duties of Neutrals*, and followed it up in 1880 by his *magnum opus*, the *Treatise on International Law*. In 1894 Hall published a useful monograph upon a little-explored topic, "The Foreign Jurisdictions of the British Crown." He died on Nov. 30, 1894.

See T. E. Holland in *Law Quarterly Review*, vol. xi.; and in *Studies in International Law*, p. 302.

HALL or **BAD-HALL** is a small spa, of about 1,400 inhabitants, on a tributary of the river Krems, Upper Austria. Local saline springs rich in bromides and iodides, though long known, have grown in popularity since 1855 when they became the property of the Government and a large new one was opened in 1925. The town is visited yearly by numbers of sufferers for treatment of scrofulous and other malignant skin diseases.

HALL (generally known as **SCHWÄBISCH-HALL**, to distinguish it from the small town of Hall in Tirol and Bad-Hall, a health resort in Upper Austria), a town of Germany, in the republic of Württemberg, situated on the Kocher, and on the railway from Heilbronn to Krailsheim, 35 m. N.E. of Stuttgart. Pop. (1925) 8,978. Hall was early of importance on account of its salt-mines, which were held as a fief of the Empire by the Salzgrafen who had their seat in the castle of Hall. The word Hall or Hal, in some form, with or without a suffix, comes into the name of many ancient towns connected with salt. Later the town belonged to the Knights Templars. It was made a free imperial city in 1276 by Rudolph of Habsburg. In 1802 it came into the possession of Württemberg. The Michaeliskirche dates from the 15th century and has fine mediaeval carving. A short distance south from the town is the castle of Kumburg, formerly a Benedictine abbey, with a church dating from the 12th century. The town is chiefly known for its production of salt, which is converted into brine and piped from Wilhelmshlück mine, 5 m. distant. The industries of the town also include cotton-spinning, tanning and the manufacture of soap, starch, brushes, machines and flat irons.

HALL, a large, undivided room; also an entrance room or passageway affording communication to other parts of a building. Originally the word was limited to the chief room of a feudal house or castle, and was applied even to the entire building, probably because in early north Europe the lord's house consisted of merely one such big room with detached out-buildings. Thus certain early houses on the border between England and Scotland, of which one remains almost intact, in the deanery at Carlisle, consisted merely of a fortified tower with one room to each floor. During the 13th and 14th centuries, as the complexity of life increased, and houses became larger and more complex, the hall still remained as the most important feature. Here was the *daïs* where the lord and his family dined, while the retainers ate in the remaining space. Here guests were received, and here, in the earlier periods, was the house fire, built on stones in the centre of the floor, as in the existing hall of Penshurst place, Kent. The hall retained its importance into the 16th century. Then, as more and more separate small rooms, easier to heat and more private, were gradually added for sleeping, eating and resting, the importance of the hall declined. It became first a ceremonial chamber, and finally merely an entrance way; it is from this that the modern usage as a passage way derives.

The typical Tudor hall was a rectangular room, usually running the entire height of the building with exposed timber trusses. At Mayfield in Sussex (c. 1350), great stone arches take the place of the trusses. At one end a narrow passageway was screened off, serving as a vestibule; the house entrance led into the passage and from there by doors through the screens into the hall. On the opposite side of the passage were the doors into the kitchen, buttery, larder and other service rooms, and above the passage the musician's gallery. At the end of the hall, opposite the screen, was the raised *daïs* (q.v.). The hall was lighted by windows high in the wall, except at the *daïs* end, where there was a bay window, and sometimes two. One or more great fireplaces furnished heat. The hall was usually roofed with timber trusses, although that of Bolsover castle in Derbyshire (late 16th century) is vaulted. Many of the trusses are of great richness and are of the type known as hammerbeam (q.v.), as in the great hall of Hampton Court palace (1534–35) and that of the Middle Temple, London (1562–72).

Halls similar to those of baronial houses were also incorporated as integral parts of other buildings such as colleges and the buildings of the great guilds, which, like many of the houses, took their names from this feature (e.g., Clothworkers' hall, Goldsmiths' hall, the Guildhall, etc.). Of these the finest examples are those of New college (1386) and Christ Church (c. 1525), both at Oxford, and Trinity college, Cambridge (1604). Among the most beautiful domestic examples are Great Chalfeld manor (c. 1450), Ightham Mote (c. 1350), Compton Wynyates (c. 1520), Montacute (between 1580 and 1601), Burton Agnes (1602–10) and Hatfield house (1611).

See J. Nash, *The Mansions of England in the Olden Time* (1839); J. A. Gotch, *Early Renaissance Architecture in England* (1901, new ed. 1914), and *Growth of the English House* (1909); T. Garner and A. Stratton, *Domestic Architecture of England During the Tudor Period* (1911). (T. F. H.)

HALLAM, HENRY (1777–1859), English historian, was the only son of John Hallam, canon of Windsor and dean of Bristol, and was born on July 9, 1777. He was educated at Eton and Christ Church, Oxford, where he graduated in 1799. Called to the bar, he practised for some years on the Oxford circuit; but his tastes were literary, and when, on the death of his father in 1812, he inherited a small estate in Lincolnshire, he gave himself up wholly to the studies of his life. His Whig connections won for him a well-paid and easy post of commissioner of stamps. He supported the abolition of the slave trade; and he was throughout his life a sincere upholder of Whig principles. General sympathy was felt for him when he lost his two brilliant sons, Arthur Henry Hallam (d. 1833), the A.H.H. of Tennyson's *In Memoriam*, and Henry Fitzmaurice Hallam (d. 1850). Hallam was a fellow of the Royal Society and a trustee of the British Museum. He died on Jan. 21, 1859. His great reputation rests on three standard works: *The View of the State of Europe during the Middle Ages* (1818; supplementary note, 1848); *Constitutional History of England* (1827); and *Introduction to the Literature of Europe in the 15th, 16th and 17th Centuries* (1838–39).

The *Middle Ages* is made up of nine long chapters, each of which is a complete treatise. The history of France, of Italy, of Spain, of Germany and of the Greek and Saracenic empires, sketched in rapid and general terms, is the subject of five separate chapters. Others deal with the great institutional features of mediaeval society—the development of the feudal system, of the ecclesiastical system and of the free political system of England. The last chapter sketches the general state of society, the growth of commerce, manners and literature in the middle ages.

The *Constitutional History of England* takes up the subject at the point at which it had been dropped in the *View of the Middle Ages*, viz., the accession of Henry VII., and carries it down to the accession of George III. An unwillingness to excite the prejudices of modern politics, which withheld him from touching perhaps the most interesting period in the history of the Constitution, did not save him from a violent attack by Southey in the *Quarterly Review*, 1828; he was accused "of heaping obloquy on all who supported the established institutions of the country." His chief unfairness was in tacitly assuming the 19th century theory of the

Constitution to be the right theory in previous centuries, and that those who departed from it on one side or the other were in the wrong. But though his work is thus coloured by his opinions, this was not the outcome of a conscious purpose, and he was scrupulously conscientious in collecting and weighing his materials. In this he was helped by his legal training, and the *Constitutional History* remains a standard authority.

Like the *Constitutional History*, the *Introduction to the Literature of Europe* continues one of the branches of inquiry opened in the *View of the Middle Ages*. The great qualities displayed in this work have been universally acknowledged—conscientiousness, accuracy, judgment and enormous reading. In science and theology, mathematics and poetry, metaphysics and law, Hallam is a competent and always a fair if not a profound critic. The bent of his own mind is manifest in his treatment of pure literature and of political speculation—which seems to be inspired with stronger personal interest and a higher sense of power than other parts of his work display.

Hallam is generally described as a "philosophical historian." The description is worthy in that he fixed his attention on results rather than on persons. His conception of history embraced the whole movement of society. But sweeping theories of the government of society, and broad characterizations of particular periods of history had no attraction for him. The view of mankind on which such generalizations are usually based, taking little account of individual character, was highly distasteful to him.

HALLAM, ROBERT (d. 1417), bishop of Salisbury and English representative at the council of Constance, was educated at Oxford, and was chancellor of the university from 1403 to 1405. In the latter year the pope nominated him to be archbishop of York, but the king objected. However, in 1407 he was consecrated by Gregory XII. at Siena as bishop of Salisbury. At the council of Pisa in 1409 he was one of the English representatives. On June 6, 1411, Pope John XXIII. made Hallam a cardinal, but there was some irregularity, and his title was not recognized. At the council of Constance (*q.v.*), which met in Nov. 1414, Hallam was the chief English envoy. In the discussions which led up to the deposition of John XXIII. on May 29, 1415, he had a leading share. With the trials of John Hus and Jerome of Prague he had less concern. Under Henry V.'s direction, he gave the emperor Sigismund vigorous support in the endeavour to secure a reform of the Church, before the council proceeded to the election of a new pope. Hallam died suddenly, on Sept. 4, 1417.

HALLÉ, SIR CHARLES (originally KARL HALLE) (1819–1895), English pianist and conductor, German by nationality, was born at Hagen, Westphalia, on April 11, 1819. He studied under Rink at Darmstadt in 1835, and in 1836 went to Paris, where for twelve years he mixed with Cherubini, Chopin, Liszt, Alfred de Musset, George Sand and other celebrities. He had started a set of chamber concerts with Alard and Franchomme, when the revolution of 1848 drove him from Paris, and he settled, with his wife and two children, in London. His pianoforte recitals, given at first from 1850 in his own house, and from 1861 in St. James's Hall, were for many years an important feature of London musical life. At the Musical Union founded by John Ella, and at the Popular Concerts from their beginning, Hallé was a frequent performer, and from 1853 he was director of the Gentlemen's Concerts in Manchester, where, in 1857, he started the famous Hallé Concerts which have remained in existence since that time. In 1888 he married Madame Norman Neruda, the violinist. In the same year he was knighted; and in 1890 and 1891 he toured with his wife in Australia and elsewhere. He died at Manchester on Oct. 25, 1895. Throughout his career Hallé was an influence of the first importance in English musical life and a consistent upholder of the highest musical ideals.

Lady Hallé, in turn, was one of the finest violinists of her time, being the first woman player to hold her own with the greatest male executants, and for many years she shared the leadership of the famous Monday and Saturday Popular Concerts with Joachim. She was born at Brünn on March 21, 1839, and died in Berlin on April 15, 1911. Queen Alexandra gave her the title of "Violinist to the Queen."

HALLE (known as HALLE-AN-DER-SAALE, to distinguish it from the small town of Halle in Westphalia), a town in the Prussian province of Saxony, situated in a sandy plain on the right bank of the Saale, which here divides into several arms, 21 m. N.W. from Leipzig by the railway to Magdeburg. Pop. (1925) 193,722.

Halle is first mentioned as a fortress erected on the Saale in 806. In 968 Halle, with the valuable salt works, was given by the emperor Otto I. to the newly founded archdiocese of Magdeburg, and in 981 Otto II. gave it a charter as a town. From the first there were separate jurisdictions for the Halloren and the German settlers in the town. The conflict of interests and jurisdictions led to the usual internecine strife during the middle ages, and both resisted the pretensions of the archbishops. In the 13th and 14th centuries it was a member of the Hanseatic League. Its liberty perished, however, as a result of the internal feud between the democratic gilds and the patrician panners. In 1478 a demagogue member of the town council, with his confederates opened the gates to the soldiers of the archbishop. The townsmen were subdued, and to hold them in check the archbishop built the castle of Moritzburg. Notwithstanding the efforts of the archbishops of Mainz and Magdeburg, the Reformation found an entrance into the city in 1522. After the peace of Westphalia in 1648 the city came into the possession of the house of Brandenburg.

Its situation at the junction of railway lines from Berlin, Breslau, Leipzig, Frankfurt-on-Main, the Harz country and Hanover, has developed the commercial and industrial importance of Halle. It consists of the old, inner town and two small towns, Glaucha in the south and Neumarkt in the north. The centre of the town is occupied by the market square, on which stand the mediaeval town hall (restored in 1883) and the Gothic Marienkirche, dating mainly from the 16th century, with two towers connected by a bridge. In the square is a bronze statue of Handel, the composer, a native of Halle. Among the churches, the St. Moritzkirche, dating from the 12th century, with fine wood carvings and sculptures, and the cathedral (belonging since 1689 to the Reformed or Calvinistic church), built in the 16th century are worthy of note. The castle of Moritzburg, formerly the residence of the archbishops of Magdeburg was destroyed by fire in the Thirty Years' War, with the exception of the left wing. The university was founded by the elector Frederick III. of Brandenburg (afterwards king of Prussia), in 1694, was closed by Napoleon in 1806 and again in 1813, but in 1815 was re-established and united with the university of Wittenberg. From the first it has been recognized as one of the principal seats of Protestant theology, originally of the pietistic and latterly of the rationalistic and critical school. It is a famous centre of agricultural research. The salt-springs of Halle which have been known from a very early period, rise within the town and on an island in the Saale. The workmen employed at the salt works are known as the *Halloren*.

Among the industries of Halle are sugar refining, machine building, the manufacture of spirits, malt, chocolate, cocoa, rubber, confectionery, cement, paper, chicory, lubricating and illuminating oil, wagon grease, carriages and playing cards, printing, dyeing and coal mining (soft brown coal). The trade is considerable, the principal exports being machinery, raw sugar and petroleum. Halle is the seat of several important publishing firms. The Bibelanstalt (Bible institution) of von Castein is the central authority for the revision of Luther's Bible, of which it sells annually thousands of copies.

HALLECK, FITZ-GREENE (1790–1867), American poet, was born at Guilford (Conn.), July 8, 1790, and died there Nov. 19, 1867. In collaboration with Joseph Rodman Drake, he contributed the "Croaker Papers" to the *New York Evening Post* in 1819, and on the death of his friend he wrote the beautiful tribute beginning "Green be the turf above thee." This poem, the title poem of *Alnwick Castle* (1827), "Burns," and the schoolboy favourite "Marco Bozzaris" mark him as a poet of slight but genuine gift.

His *Life and Letters* by J. G. Wilson appeared in 1869. His *Poetical Writings* were edited by Wilson in the same year.

HALLECK, HENRY WAGER (1815–1872), American general and jurist, was born at Westernville, Oneida county, N.Y., in 1815. Upon graduating from West Point military academy in 1839 he was appointed to the engineers, and in 1845 he was sent by the Government to visit the principal military establishments of Europe. After his return, Halleck delivered a course of lectures on the science of war, published in 1846 under the title *Elements of Military Art and Science*, a later edition of which was widely used as a text-book by volunteer officers during the Civil War. On the outbreak of the Mexican War in 1846, he served with the expedition to California and the Pacific coast, acting for several years in California as a staff officer, and as secretary of State under the military government, and in 1849 he helped to frame the State Constitution of California. In 1854 Capt. Halleck resigned his commission and took up the practice of law with great success. On the outbreak of the Civil War he returned to the army as a major-general, and in Nov. 1861 he was charged with the supreme command in the western theatre of war.

There can be no doubt that his administrative skill was mainly instrumental in bringing order out of chaos in the hurried formation of large volunteer armies in 1861, but the strategical and tactical successes of the following spring were due rather to the skill and activity of his subordinate generals, Grant, Buell and Pope, than to the plans of the supreme commander. In July, however, he was called to Washington as general-in-chief of the armies. At headquarters his administrative powers were conspicuous, but he proved to be utterly wanting in any large grasp of the military problem; the successive reverses of McClellan, Pope, Burnside and Hooker in Virginia were not infrequently traceable to the defects of the general-in-chief. In March 1864 Grant was appointed to replace him, Halleck becoming chief of staff at Washington. This post he occupied with credit until the end of the war. Halleck's position as a soldier is easily defined by his uniform success as an administrative official, his equally uniform want of success as an officer at the head of large armies in the field, and the popularity of his theoretical writings on war. While his interference with the dispositions of the commanders in the field was often disastrous, his services in organizing and instructing Union forces were of high value. He died at Louisville, Ky., Jan. 9, 1872.

Besides *Military Art and Science*, Halleck wrote *Bitumen, its Varieties, Properties and Uses* (1841); *The Mining Laws of Spain and Mexico* (1859); *International Law* (1861; new ed., 1908); and *Treatise on International Law and the Laws of War, prepared for the use of Schools and Colleges*, abridged from the larger work. He translated Jomini's *Vie politique et militaire de Napoléon* (1864) and de Fooz *On the Law of Mines* (1860). The works on international law mentioned above entitle Gen. Halleck to high rank among the jurists of the 19th century.

See R. N. R. Phelps, *Stanton and Halleck in the Civil War* (1905); J. G. Wilson, "Types and Traditions of the Old Army," in *Journal of Military Service Institute*, vol. xxxvii., pp. 333–356 (1905).

HÄLLEFLINTA (a Swedish word meaning rock-flint), a white, grey, yellow, greenish or pink, fine-grained rock consisting of an intimate mixture of quartz and felspar. Many examples are banded or striated; others contain porphyritic crystals of quartz which resemble those of the felsites and porphyries. Mica, iron oxides, apatite, zircon, epidote and hornblende may also be present in small amount. The more micaceous varieties form transitions to granulite and gneiss. Hälleflinta under the microscope is very finely crystalline, or even cryptocrystalline, resembling the felsitic matrix of many acid rocks. It is essentially metamorphic and occurs with gneisses, schists and granulites, especially in the Scandinavian peninsula, where it is regarded as being very characteristic of certain horizons. Of its original nature there is some doubt, but its chemical composition and the occasional presence of porphyritic crystals indicate that it has affinities to the fine-grained acid intrusive rocks. In this group there may also have been placed metamorphosed acid tuffs and a certain number of adinoles (shales, contact-altered by intrusions of dolerite). The assemblage is not a perfectly homogeneous one but includes both igneous and sedimentary rocks, but the former preponderate. Rocks very similar to the typical Swedish hälleflintas occur in Tirol, in Galicia and eastern Bohemia.

HALLEL, a Jewish liturgical term, including "the great Hallel" or Ps. cxxxvi. and "the Egyptian Hallel," Ps. cxiii.–cxviii., possibly so-called because of Ps. cxiv. (Hebrew "praise," cf. Halleluiah "Praise ye Jah," cognate to Arabic root *hállala*, to sing praises at the new moon or *Hilál*). According to the Talmud (Arachin 10) Hallel was recited on certain festivals. On the new moon, a minor festival, and on the last six days of passover, on account of the drowning of the Egyptians, the Hallel is curtailed. The blessing preceding the Hallel varies, in certain rites, when this curtailing occurs. Some of the Hallel is recited antiphonally. At the conclusion of the Hallel a doxology is pronounced. At the domestic passover service, Hallel is recited, as it was in the Temple days (Pesachim x., 4). Jesus followed this custom (Mark xiv. 26). On tabernacles the *Lulab* (palm branch) is waved during Hallel. Originally the Hallel consisted of Ps. cxiii. (school of Shammai) or cxiv. (school of Hillel). The other psalms were probably added about A.D. 160.

BIBLIOGRAPHY.—On the Hallel generally see S. Singer's *Authorized Daily Prayerbook* (1928, pp. 219 sqq.) and I. Abraham's notes in the annotated edition; I. Elbogen, *Der Jüd. Gottesdienst* (Frankfurt a. M., 1924, s.v. in index); *Jewish Encycl.*, where also music and references to other settings are given.

HALLER, ALBRECHT VON (1708–1777), Swiss anatomist and physiologist, was born at Berne on Oct. 16, 1708. Prevented by ill-health from joining in sports, he developed an amazing precocity. He studied medicine at Tübingen under Camerarius, and then at Leyden under Boerhaave and Albinus, graduating in 1727 with a thesis that proved the so-called salivary duct, claimed as a recent discovery by Coschwitz, to be merely a blood vessel. After visiting London, Oxford and Paris, in 1728 he went to Basle where the awakening of his interests in botany led him to begin a collection of plants which was afterwards the basis of his great work on Swiss flora. About the same time he wrote his poem *Die Alpen*, describing the charm of the simple and idyllic life of the Alpine inhabitants. It was included in the first edition of his *Gedichte* (1732).

In 1730 von Haller began to practise as a physician in Berne, but the fame of his botanical and anatomical researches led George II., in 1736, to offer him the chair of medicine, anatomy, surgery and botany in the newly-founded university of Göttingen, a chair which he held for 17 years, conducting at the same time a monthly journal (the *Göttingische gelehrte Anzeiger*), to which he is said to have contributed some 12,000 articles on almost every branch of knowledge. In 1753 von Haller resigned his chair and returned to Berne, where, during the remaining 21 years of his life, which were largely occupied with various municipal and State duties, he prepared his *Bibliotheca medica*, the botanical, surgical and anatomical parts of which he lived to complete, wrote three philosophical romances—*Usonia* (1771), *Alfred* (1773) and *Fabius and Cato* (1774), expounding his views on various types of government, and produced, among other medical works, the justly-famed *Elementa physiologiae corporis humani* (1757–60). Von Haller died on Dec. 17, 1777.

Among von Haller's most important contributions to medicine may be named his recognition of the mechanism of respiration and the automatism of the heart, his admission of the use of bile in the digestion of fat, his descriptions of the development of the embryo, his work on the anatomy of the organs of generation, of the brain, of the heart and of many imperfectly-known arteries, and above all his classification of the bodily parts as sensible and insensible, irritable and non-irritable, together with his noteworthy demonstration that sensibility and irritability are independent, the former being a property of tissues endowed with nerves, the latter a peculiarity of all muscular tissue, independent of the nerves proceeding to it and surviving in severed parts.

BIBLIOGRAPHY.—Apart from the works mentioned above von Haller's chief writings are *Enumeratio methodica stirpium Helveticarum* (1742); *Icones anatomicae* (1743–54); *Disp. anatomicae Selectiores* (1746–52); *De respiratione experimenta anatomica* (1747); *Opuscula botanica* (1749); *Opuscula pathologica* (1754); an edition of Boerhaave's *Artis medicae principia* (1769) and *Disp. chirurg. collectio* (1777). See J. G. Zimmermann, *Das Leben des Herrn von Haller* (Zürich, 1755), and the detailed biography in L. Hirzel's edition of the *Gedichte* (Frauenfeld, 1882).

HALLER, BERTHOLD (1492-1536), Swiss reformer, was born at Aldingen, Württemberg, and after studying at Pforzheim, where he met Melanchthon, and at Cologne, taught in the gymnasium at Berne. Even before his acquaintance with Zwingli in 1521 he had begun to preach the Reformation, his sympathetic character and his eloquence making him a great force. In 1526 he was at the abortive conference of Baden, and in January 1528 drafted and defended the ten theses for the conference of Berne which established the new religion in that city. He left no writings except a few letters which are preserved in Zwingli's works. He died on Feb. 25, 1536.

See C. Pestalozzi, *Berthold Haller* (Elberfeld, 1861).

HALLEY, EDMUND (1656-1742), English astronomer, was born in London, on Oct. 29, 1656. He was educated at St. Paul's school, London, and at Queen's college, Oxford. He studied astronomy in his schooldays, and in 1676 published a paper on the planetary orbits. Wishing to observe in the southern hemisphere, he embarked for St. Helena in Nov. 1676. Here he catalogued 341 stars, observed a transit of Mercury, and made numerous pendulum observations. Upon his return to England he began a friendship with Newton, which resulted in the publication of the *Principia*, the expense of this work being borne by Halley. He observed the comet of 1682, calculated its orbit, and predicted its return in 1757, this being the first prediction of a comet's return ever made. (See COMET.) In 1703 he was appointed Savilian professor of geometry at Oxford and in 1720 he succeeded Flamsteed as astronomer-royal. Although in his 64th year, he undertook to observe the moon through an entire revolution of her nodes (18 years), and actually carried out his purpose. Halley also detected the proper motions of the stars (1718), the acceleration of the moon's mean motion, and the long inequality of Jupiter and Saturn; and indicated first in 1679, and again in 1716, *Phil. Trans.*, No. 348, a method extensively used in the 18th and 19th centuries for determining the solar parallax by means of the transits of Venus. He died on Jan. 14, 1742.

His principal works are *Catalogus stellarum australium* (London, 1679), the substance of which was embodied in vol. iii. of Flamsteed's *Historia coelestis* (1725); *Synopsis astronomiae cometicae* (Oxford, 1705); *Astronomical Tables* (London, 1752); also 81 miscellaneous papers of considerable interest, scattered through the *Philosophical Transactions*. To these should be added his version from the Arabic (which language he acquired for the purpose) of the treatise of Apollonius *De sectione rationis*, with a restoration of his two lost books *De sectione spatii*, both published at Oxford in 1706; also his fine edition of the *Comics* of Apollonius, with the treatise by Serenus *De sectione cylindri et conici* (Oxford, 1710, folio). His edition of the *Spherics* of Mene-laus was published by his friend Costard in 1758.

Rudolph, *Bulletin of Bibliography*, No. 14 (Boston, 1904); E. F. McPike, "Bibliography of Halley's Comet," *Smithsonian Misc. Collections* (1903); *Notes and Queries*, 9th series, vols. x, xi, xii, 10th series, vol. ii. (E. F. McPike). A collection of manuscripts regarding Halley is preserved among the Rigaud papers in the Bodleian library.

HALLGRÍMSSON, JÓNAS (1807-1844), the chief lyrical poet of Iceland, was born in 1807 at Steinsstaðir in Eyjafjardarsýsla in the north of that island, and educated at the famous school of Bessastaðir and at the University of Copenhagen. He went to Iceland on a geological mission (1837-42) from the Danish Government; and made many interesting scientific observations. But his fame rests on his Icelandic poems and short stories. The study of the German masters and the old classical writers of Iceland opened his eyes to the corrupt state of Icelandic poetry. The misuse of the Eddic metaphors made the lyrical and epical poetry of the day hardly intelligible, and the language of the poets was mixed up with words of German and Danish origin. The great Danish philologist and friend of Iceland, Rasmus Rask, and the poet Bjarni Thórarensen had done much to purify the language, but Jonas Hallgrímsson completed their work by his poems and tales, in a purer language than ever had been written in Iceland since the days of Snorri Sturlason. The excesses of Icelandic poetry were specially seen in the so-called *rímur*, ballads

of heroes, etc., which were fiercely attacked by Jónas Hallgrímsson, who at last succeeded in converting the educated to his view. Most of the principal poems, tales and essays of Jónas Hallgrímsson appeared in the periodical *Fjölnir*, which he began publishing at Copenhagen in 1835, together with Konráð Gíslason, and the patriotic Thómas Saemundsson. When *Fjölnir* at last ceased, its programme and spirit still lived in *Ný Félagsrit* and other patriotic periodicals which took its place. Jónas Hallgrímsson, who died in 1844, is the father of a separate school in Icelandic lyric poetry. He introduced foreign thoughts and metres, but at the same time revived the metres of the Icelandic classical poets. Although his poetical works are all comprised in one small volume, he strikes every string of the old harp of Iceland.

HALLIDAY, ANDREW (ANDREW HALLIDAY DUFF) (1830-1877), British journalist and dramatist, was born at Mar-noch, Banffshire. He was the author, alone and with others, of a great number of farces, burlesques and melodramas, and a peculiarly successful adapter of popular novels for the stage. Of these *Little Em'ly* (1869), his adaptation of *David Copperfield*, had a long run at Drury Lane. Halliday died in London on April 10, 1877.

HALLIWELL-PHILLIPS, JAMES ORCHARD (1820-1889), English Shakespearian scholar, son of Thomas Halliwell, was born in London June 21, 1820 and educated privately and at Jesus college, Cambridge. In 1839 he edited Sir John Mandeville's *Travels*; in 1842 published an *Account of the European MSS. in the Chetham Library*, besides a newly discovered metrical romance of the 15th century (*Torrent of Portugal*). He became best known, however, as a Shakespearian editor and collector. In 1848 he brought out his *Life of Shakespeare*, which passed through several editions; in 1853-65 a sumptuous edition, limited

to 150 copies, of Shakespeare in folio, with full critical notes; in 1863 a *Calendar of the Records at Stratford-on-Avon*; in 1864 a *History of New Place*. After 1870 he devoted his attention to elucidating Shakespeare's life. He exhausted the available records in his *Outlines of the Life of Shakespeare* (privately printed 1881, other eds. 1882, etc.). He was a prime mover in the purchase of New Place for the corporation of Stratford-on-Avon, and in the formation there of the Shakespeare museum. His house, Hollingbury Copse, near Brighton, was full of rare and curious works, many of which he gave to the Chetham library, Manchester, to the town library of Penzance, to the Smithsonian Institution, Washington, and to the library of Edinburgh university. He died on Jan. 3, 1889.

Halliwell-Phillips' works are very numerous. He edited many early English and Elizabethan works for the Percy, Camden and Shakespeare Societies, and prepared the valuable *Dictionary of Old English Plays* (1860).

HALLOWE'EN or **ALL HALLOWS EVE**, the name given to Oct. 31, as the vigil of Halloween or All Saints' Day, now chiefly known as the eve of the Christian festival. It long antedates Christianity. The two chief characteristics of ancient Hallowe'en were the lighting of bonfires and the belief that this is the one night in the year during which ghosts and witches are most likely to wander abroad. History shows that the main celebrations of Hallowe'en were purely Druidical, and this is further

"BOBBING FOR APPLES," (FROM THE LOUTERELL PSALTER)

"It is customary," says Brand, "on this night for young people to dive for apples, or catch at them when stuck upon one end of a kind of hanging beam, at the other extremity of which is fixed a lighted candle, and that with their mouths only, their hands being tied behind their backs"

proved by the fact that in parts of Ireland Oct. 31 is still known as *Oidhche Shamhna*, "Vigil of Saman." This is directly connected with the Druidic belief in the calling together of certain wicked souls on Hallowe'en by Saman, lord of death. On the Druidic ceremonies were grafted some of the characteristics of the Roman festival in honour of Pomona held about Nov. 1, in which nuts and apples, representing the winter store of fruits, played an important part. The custom of lighting Hallowe'en fires survived until recently in the highlands of Scotland and Wales.

For details of the Hallowe'en games and bonfires see Brand's *Antiquities of Great Britain*; Chambers's *Book of Days*; Grimm's *Deutsche Mythologie*, ch. xx. (*Elemente*), ch. xxxiv. (*Aberglaube*); and J. G. Frazer's *Golden Bough*, vol. iii. (See BELTANE and BONFIRE.)

HALLSTATT. The first iron age of Central and Western Europe and the Balkans is known as the Hallstatt period after the place of that name in Upper Austria. It is not the cradle of the earliest iron age culture, but the site where objects characteristic of it were first identified. Here, between 1846-99, upwards of 2,000 graves were found. The majority fall into two groups, an earlier (c. 900-700 B.C.) and a later (c. 700-400 B.C.). Hallstatt became an important settlement in the first iron age. Both cremation and inhumation were practised, the latter slightly preponderating. The cremation graves are on the whole the richer and, viewed in the mass, contain older objects than the inhumation burials, but this should not be pressed too strictly, for the two rites overlapped chronologically. Most of the types of grave-furniture are found elsewhere in phase C and D burials (see below), but objects of a peculiar character occur as well. The pottery unearthed by the earlier excavators was practically all destroyed. Near by lies the prehistoric salt mine where salt was extensively obtained. A number of shafts were sunk, often to a considerable depth, sometimes at a steep angle. Thanks to the preservative nature of the salt, their implements, parts of their clothing and even (at Hallein as well as at Hallstatt) the bodies of the miners themselves have come to light.

Typology and Art.—Reinecke divides the Hallstatt period into four phases, A-D (see EARLY IRON AGE). He equates the first of these with the period of the Urn-field culture. Schumacher regards the latter as comprising the last phase of the bronze and the first of the iron ages. Others hold that Hallstatt A and B are in reality the latest bronze age, and that the iron age did not begin until Hallstatt C. Others regard it as the last period of the bronze age. The fourfold division is adhered to in the following account.

Phase A.—Iron, though known, is very rare, but Villanovan influences are already apparent. The rite is cremation, in cemeteries of flat graves (or under very low mounds). The pottery in south-west Germany is thin-walled, of various forms, some types betraying strong metallic influence. The large urns often contain a number of smaller vessels (fig. 1). Further east (Stillfried, Mariarast, etc.) the Silesian influence (Lusatian B) is noticeable in much of the pottery. Among the metal objects are:—Antennae, Ronzano (fig. 2) and other bronze swords; razors (fig. 3) and knives, compound fibulae, and, in the east harp and simple bow brooches, torcs, pins, the so-called "Old Italian" bronze vessels: cups, vessels with "sun-boat and swans" (fig. 5), etc.

Phase B, if it can be said to have a general chronological significance, is marked by the reassertion of the old bronze age population of South-west Germany over the comparatively newly-come Urnfield peoples. It is confined to the more western regions. The tumulus again becomes common; cremation is the usual rite. The pottery (sometimes polychrome) is extremely well-made and of various forms. The urns are often globular in body and with funnel-shaped necks (fig. 6) and influenced by Hallstatt A and older bronze age forms. The chief metal objects which have been found are the slender bronze Hallstatt sword with winged or slightly scrolled chapes (fig. 7) and the vase-headed pin (fig. 8).

Phase C.—Iron is first in general use. The rite is mixed; the tumulus prevails. The pottery is both polychrome and unpainted (often with polished graphite slip). In the west, the urns are

more onion-shaped than in phase B (fig. 14); the bronze age chip-carving (*Kerbschnitt*) reappears. In the east—Moravia, eastern Austria, etc.—where the culture of D is not represented, this phase probably lasted longer. The urns (graphite or polychrome) have often high conical necks (fig. 12); the so-called "Moon-idols," their horns often ending in beasts' heads, are very characteristic (fig. 13). Among the many metal types are:—long, heavy iron and bronze swords with beautifully scrolled chapes; the winged Hallstatt axe (fig. 11); long bronze girdle-mounts with *répoussé* ornamentation (fig. 13); various types of pins (figs. 9 and 10); fibulae, rare in the west (spiral spectacle and half-moon brooches), in the East, these and other types; bronze vessels (broadly ribbed bucket and other types; chariot-and-horse-harness—among the latter, the pointed tutulus (fig. 17) a type which occurs in the warrior's tomb at Corneto, and gives a synchronism with Italy (see ITALY, IRON AGE).

Phase D.—Not represented in Eastern Austria, etc., but lasts until the appearance of the La Tène period (s.v.) in other areas. The tumulus prevails; the rite is mostly inhumation. The pottery, which is not common, degenerates; the urns are derived from C forms but are less crisp in profile (fig. 19). Among the metal objects are:—the dagger-sword (sometimes one-edged) with "horse-shoe" or antennae hilt; pins are rare, brooches common (the drum, cup (fig. 18), and the later variants of the bow and serpentine fibulae). A variety of ring ornaments: ear- (fig. 16), neck-, arm- and foot-rings; girdle mounts, shorter than in C, sometimes in pierced work (fig. 15). Bronze vessels, among which, the narrowly-ribbed bucket, and in upper Italy and the Veneto-Illyrian zone, situlae with figured motifs in friezes, stylized scenes from every day life. Early archaic Greek vessels appear in the west, Pertuis (fig. 20) Grachwyl, etc. Amber occurs in C and D, gold mostly in D; ivory, lignite, jet and coral are not unknown, the last in D.

Hallstatt art, with the exception of the Veneto-Illyrian "situla style," is severely geometric in feeling; the advances made were on technical rather than aesthetic lines. It reveals indirect connections with the Greek Dipylon art, but developments of older bronze age elements are more prominent. There is a general tendency towards the extravagant, the baroque. The Greek orientaling influence is hardly felt. Even the figural motifs are geometric in feeling as is shown by urns from Oedenburg, and many of the girdle-mounts; these are mainly confined to the Austrian area. The typical bird motif, probably derived from Italy, may perhaps be traced back to late Helladic times in Greece. Plant patterns are very rare and strongly stylized (Urmitz). Among the other motifs are lozenges, triangles, concentric circles, arcs, chevrons, "garlands," herring-bone groups of parallel lines (sometimes grooved), and occasionally the swastika, triskele and meander, etc. Contrasts in colour and the breaking up of smooth surfaces were in favour. The arrangement of figures in pairs is very characteristic. In H₂ pottery we find designs grouped in a circular field around a star or cross, or arranged in bands. Generally speaking, the arrangement consists in mechanical repetitions and a rigid regard for symmetry, rather than in the treatment of the design as an organic whole. Compared with the art of the northern bronze age, or of the La Tène period, the Hallstatt style is lifeless and sterile.

HALLUCINATION, a psychological term which has been the subject of much controversy, and to which, although there is now fair agreement as to its denotation, it is still impossible to give a precise and entirely satisfactory definition (from Lat. *alucinari* or *allucinari*, to wander in mind, Gr. ἀλῦσσειν or ἀλῦειν, from ἀλῆ, wandering). Hallucinations constitute one of the two great classes of all false sense-perceptions, the other class consisting of the "illusions," and the difficulty of definition is clearly to mark the boundary between the two classes. *Illusion* may be defined as the misinterpretation of sense-impression, while *hallucination*, in its typical instances, is the experiencing of a sensory presentation, *i.e.*, a presentation having the sensory vividness that distinguishes perceptions from representative imagery, at a time when no stimulus is acting on the corresponding sense-organ. There is, however, good reason to think that in many cases, possibly in all cases, some stimulation of the sense-organ, coming either from without or from within the body, plays a part in the genesis of the hallucination. This being so, we must be content to leave the boundary between illusions and hallucinations ill-defined, and to regard as illusions *those false perceptions in which impressions made on the sense-organ play a leading part in determining the character of the percept*, and as hallucinations *those in which any such impression is lacking, or plays but a subsidiary part and bears no obvious relation to the character of the false percept*.

As in the case of illusion, hallucination may or may not involve delusion, or belief in the reality of the object falsely perceived. Among the sane the hallucinatory object is frequently recognized at once as unreal or at least as but quasi-real; and it is only the insane, or persons in abnormal states, such as hypnosis, who, when an hallucination persists or recurs, fail to recognize that it corresponds to no physical impression from, or object in, the outer world. Hallucinations of all the senses occur, but the most commonly reported are the auditory and the visual, while those of the other senses seem to be comparatively rare. This apparent difference of frequency is no doubt largely due to the more striking character of visual and auditory hallucinations, and to the relative difficulty of ascertaining, in the case of perceptions of the lower senses, *e.g.*, of taste and smell, that no impression adequate to the genesis of the percept has been made upon the sense-organ; but, in so far as it is real, it is probably due in part to the more constant use of the higher senses and the greater strain consequently thrown upon them, in part also to their more intimate connection with the life of ideas.

The hallucinatory perception may involve two or more senses, *e.g.*, the subject may seem to see a human being, to hear his voice and to feel the touch of his hand. This is rarely the case in spontaneous hallucination, but in hypnotic hallucination the subject is apt to develop the object suggested to him, as present to one of his senses, and to perceive it also through other senses.

Among visual hallucinations the human figure, and among auditory hallucinations human voices, are the objects most commonly perceived. The figure seen always appears localized more or less definitely in the outer world. In many cases it appears related to the objects truly seen in just the same way as a real object; *e.g.*, it is no longer seen if the eyes are closed or turned away, it does not move with the movements of the eyes, and it may hide objects lying behind it, or be hidden by objects coming between the place that it appears to occupy and the eye of the percipient. Visual hallucinations are most often experienced when the eyes are open and the surrounding space is well or even brightly illuminated. Less frequently the visual hallucination takes the form of a self-luminous figure in a dark place or appears in a luminous globe or mist which shuts out from view the real objects of the part of the field of view in which it appears.

Auditory hallucinations, especially voices, seem to fall into two distinct classes: (1) those which are heard as coming from without, and are more or less definitely localized in outer space, (2) those which seem to be within the head or, in some cases, within the chest, and to have less definite auditory quality. It seems probable that the latter are hallucinations involving principally kinaesthetic sensations, sensations of movement of the

organs of speech.

Hallucinations occur under a great variety of bodily and mental conditions, which may conveniently be classified as follows:

I. CONDITIONS WHICH IMPLY NORMAL WAKING CONSCIOUSNESS AND NO DISTINCT DEPARTURE FROM BODILY AND MENTAL SANITY

a. It would seem that a considerable number of perfectly healthy persons occasionally experience, while in a fully waking state, hallucinations for which no cause can be assigned. The census of hallucinations conducted by the Society of Psychical Research showed that about 10% of all sane persons can remember having experienced at least one hallucination while they believed themselves to be fully awake and in normal health. These sporadic hallucinations of waking healthy persons are far more frequently visual than auditory, and they usually take the form of some familiar person in ordinary attire. The figure in many cases is seen, on turning the gaze in some new direction, fully developed and lifelike, and its hallucinatory character may be revealed only by its noiseless movements, or by its fading away *in situ*. A special interest attaches to hallucinations of this type, owing to the occasional coincidence of the death of the person with his hallucinatory appearance. The question raised by these coincidences will be discussed in a separate paragraph below.

b. A few persons, otherwise normal in mind and body, seem to experience repeatedly some particular kind of hallucination. The voice (*δαυμόνιον*) so frequently heard by Socrates, warning or advising him, is the most celebrated example of this type.

II. CONDITIONS MORE OR LESS UNUSUAL OR ABNORMAL BUT NOT IMPLYING DISTINCT DEPARTURE FROM HEALTH

a. A kind of hallucination to which perhaps every normal person is liable is that known technically as "recurrent sensation." This kind is experienced only when some sense-organ has been continuously or repeatedly subjected to some one kind of impression or stimulation for a considerable period; *e.g.*, the microscopist, after examining for some hours one particular kind of object or structure, may suddenly perceive the object faithfully reproduced in form and colour, and lying, as it were, upon any surface to which his gaze is directed. Perhaps the commonest experience of this type is the recurrence of the sensations of movement at intervals in the period following a sea voyage or long railway journey.

b. A considerable proportion of healthy sane persons can induce hallucinations of vision by gazing fixedly at a polished surface or into some dark translucent mass; or of hearing, by applying a large shell or similar object to the ear. These methods of inducing hallucinations, especially the former, have long been practised in many countries as modes of divination, various objects being used, *e.g.*, a drop of ink in the palm of the hand, or a polished finger-nail. The object now most commonly used is a polished sphere of clear glass or crystal (*see* CRYSTAL-GAZING). Hence such hallucinations go by the name of *crystal visions*. The crystal vision often appears as a picture of some distant or unknown scene lying, as it were, in the crystal; and in the picture figures may come and go, and move to and fro, in a perfectly natural manner. In other cases, written or printed words or sentences appear. The percipient, seer or scryer, commonly seems to be in a fully waking state as he observes the objects thus presented. He is usually able to describe and discuss the appearances, successively discriminating details by attentive observation, just as when observing an objective scene; and he usually has no power of controlling them, and no sense of having produced them by his own activity. In some cases these visions have brought back to the mind of the scryer facts or incidents which he could not voluntarily recollect. In other cases they are asserted by credible witnesses to have given to the scryer information, about events distant in time or place, that had not come to his knowledge by normal means. These cases have been claimed as evidence of telepathic communication or even of clairvoyance. But at present the number of well-attested cases of this sort is too small to justify acceptance of this conclusion by those who have only second-

hand knowledge of them.

c. Prolonged deprivation of food predisposes to hallucinations, and it would seem that, under this condition, a large proportion of otherwise healthy persons become liable to them, especially to auditory hallucinations.

d. Certain drugs, notably opium, Indian hemp and mescal predispose to hallucinations, each tending to produce a peculiar type. Thus Indian hemp and mescal, especially the latter, produce in many cases visual hallucinations in the form of a brilliant play of colours, sometimes a mere succession of patches of brilliant colour, sometimes in architectural or other definite spatial arrangement.

e. The states of transition from sleep to waking, and from waking to sleep, seem to be peculiarly favourable to the appearance of hallucinations. The recurrent sensations mentioned above are especially prone to appear at such times, and a considerable proportion of the sporadic hallucinations of persons in good health are reported to have been experienced under these conditions. The name "hypnagogic" hallucinations, first applied by Alfred Maury, is commonly given to those experienced in these transition states.

f. The presentations, predominantly visual, that constitute the principal content of most dreams, are generally described as hallucinatory, but the propriety of so classing them is very questionable. The present writer is confident that his own dream-presentations lack the sensory vividness which is the essential mark of the percept, whether normal or hallucinatory, and which is the principal, though not the only, character in which it differs from the representation or memory-image. It is true that the dream-presentation, like the percept, differs from the representative imagery of waking life in that it is relatively independent of volition; but that seems to be merely because the will is in abeyance or very ineffective during sleep. The wide currency of the doctrine that classes dream-images with hallucinations seems to be due to this independence of volitional control, and to the fact that during sleep the representative imagery appears without that rich setting of undiscriminated or marginal sensation which always accompanies waking imagery, and which by contrast accentuates for introspective reflection the lack of sensory vividness of such imagery.

g. Many of the subjects who pass into the deeper stages of hypnosis (*see* HYPNOSIS) show themselves, while in that condition, extremely liable to hallucination, perceiving whatever object is suggested to them as present, and failing to perceive any object of which it is asserted by the operator that it is no longer present. The reality of these positive and negative hallucinations of the hypnotized subject has been recently questioned, it being maintained that the subject merely gives verbal assent to the suggestions of the operator. But that the hypnotized subject does really experience hallucinations seems to be proved by the cases in which it is possible to make the hallucination, positive or negative, persist for some time after the termination of hypnosis, and by the fact that in some of these cases the subject, who in the post-hypnotic state seems in every other respect normal and wide awake, may find it difficult to distinguish between the hallucinatory and real objects. Further proof is afforded by experiments such as those by which Alfred Binet showed that a visual hallucination may behave for its percipient in many respects like a real object, *e.g.*, that it may appear reflected in a mirror, displaced by a prism and coloured when a coloured glass is placed before the patient's eyes. It was by means of experiments of this kind that Binet showed that hypnotic hallucinations may approximate to the type of the illusion, *i.e.*, that some real object affecting the sense-organ (in the case of a visual hallucination some detail of the surface upon which it is projected) may provide a nucleus of peripherally excited sensation around which the false percept is built up. An object playing a part of this sort in the genesis of an hallucination is known as a "*point de repère*." It has been maintained that all hallucinations involve some such *point de repère* or objective nucleus; but there are good reasons for rejecting this view.

h. In states of ecstasy, or intense emotional concentration of attention upon some one ideal object, the object contemplated

seems at times to take on sensory vividness, and so to acquire the character of an hallucination. In these cases the state of mind of the subject is probably similar in many respects to that of the deeply hypnotized subject and these two classes of hallucination may be regarded as very closely allied.

III. HALLUCINATIONS WHICH OCCUR AS SYMPTOMS OF BOTH BODILY AND MENTAL DISEASES

a. Dr. H. Head has the credit of having shown for the first time, in the year 1901, that many patients, suffering from more or less painful visceral diseases, disorders of heart, lungs, abdominal viscera, etc., are liable to experience hallucinations of a peculiar kind. These "visceral" hallucinations, which are constantly accompanied by headache of the reflected visceral type, are most commonly visual, more rarely auditory. In all Dr. Head's cases the visual hallucination took the form of a shrouded human figure, colourless and vague, often incomplete, generally seen by the patient standing by his bed when he wakes in a dimly lit room. The auditory "visceral" hallucination was in no instance vocal, but took such forms as sounds of tapping, scratching or rumbling, and were heard only in the absence of objective noises. In a few cases the "visceral" hallucination was bisensory, *i.e.*, both auditory and visual.

In all these respects the "visceral" hallucination differs markedly from the commoner types of the sporadic hallucination of healthy persons.

b. Hallucinations are constant symptoms of certain general disorders in which the nervous system is involved, notably of the *delirium tremens*, which results from chronic alcohol poisoning, and of the delirium of the acute specific fevers. The hallucinations of these states are generally of a distressing or even terrifying character. Especially is this the rule with those of *delirium tremens*, and in the hallucinations of this disease certain kinds of objects, *e.g.*, rats and snakes, occur with curious frequency.

c. Hallucinations occasionally occur as symptoms of certain nervous diseases that are not usually classed with the insanities, notably in cases of epilepsy and severe forms of hysteria. In the former disorder, the sensory aura that so often precedes the epileptic convulsion may take the form of an hallucinatory object, which in some cases is very constant in character. Unilateral hallucinations, an especially interesting class, occur in severe cases of hysteria, and are usually accompanied by hemi-anaesthesia of the body on the side on which the hallucinatory object is perceived.

d. Hallucinations occur in a large, but not accurately definable, proportion of all cases of mental disease proper. Two classes are recognized: (1) those that are intimately connected with the dominant emotional state or with some dominant delusion; (2) those that occur sporadically and have no such obvious relation to the other symptoms of disease. Hallucinations of the former class tend to accentuate, and in turn to be confirmed by, the congruent emotional or delusional state; but whether these are to be regarded as primary symptoms and as the cause of the hallucinations, or *vice versa*, it is generally impossible to say. Patients who suffer delusions of persecution are very apt to develop later in the course of their disease hallucinations of the voices of their persecutors; while in other cases hallucinatory voices, which are at first recognized as such, come to be regarded as real and in these cases seem to be factors of primary importance in the genesis of further delusions. Hallucinations occur in almost every variety of mental disease, but are commonest in the forms characterized by a cloudy dream-like condition of consciousness, and in extreme cases of this sort the patient (as in the delirium of chronic alcohol-poisoning) seems to move waking through a world consisting largely of the images of his own creation, set upon a background of real objects.

In some cases hallucinations are frequently experienced for long periods in the absence of any other symptom of mental disorder, but these no doubt usually imply some morbid condition of the brain.

Physiology of Hallucination.—There has been much discussion as to the nature of the neural process in hallucination. It

is generally and rightly assumed that the hallucinatory perception of any object has for its immediate neural correlate a state of excitement which, as regards its characters and its distribution in the elements of the brain, is entirely similar to the neural correlate of the normal perception of the same object. The hallucination is a perception, though a false perception. In the perception of an object and in the representation of it, introspective analysis discovers a number of presentative elements. In the case of the representation these elements are memory images only (except perhaps in so far as actual kinaesthetic sensations enter into its composition); whereas, in the case of the percept, some of these elements are sensations, sensations which differ from images in having the attribute of sensory vividness; and the sensory vividness of these elements lends to the whole complex the sensory vividness or reality, the possession of which character by the percept constitutes its principal difference from the representation. Normally, sensory vividness attaches only to those presentative elements which are excited through stimulations of the sense-organs. The normal percept, then, owes its character of sensory reality to the fact that a certain number of its presentative elements are sensations peripherally excited by impressions made upon a sense-organ. The problem is, then, to account for the fact that the hallucination contains presentative elements that have sensory vividness, that are sensations, although they are not excited by impressions from the external world falling upon a sense-organ. Most of the discussions of this subject suffer from the neglect of this preliminary definition of the problem. Many authors, notably W. Wundt and his disciples, have been content to assume that the sensation differs from the memory-image only in having a higher degree of intensity; from which they infer that its neural correlate in the brain cortex also differs from that of the image only in having a higher degree of intensity. For them an hallucination is therefore merely a representation whose neural correlate involves an intensity of excitement of certain brain-elements such as is normally produced only by peripheral stimulation of sensory nerves in the sense-organs. But this view, so attractively simple, ignores an insuperable objection. Sensory vividness is not to be identified with superior intensity; for while the least intense sensation has it, the memory image of the most intense sensation lacks it completely. And, since intensity of sensation is a function of the intensity of the underlying neural excitement, we may not assume that sensory vividness is also the expression in consciousness of that intensity of excitement. If Wundt's view were true a progressive diminution of the intensity of a sensory stimulus should bring the sensation to a point in the scale of diminishing intensity at which it ceases to be sensation, ceases to have sensory vividness and becomes an image merely. But this is not the case; with diminishing intensity of stimulation, the sensation declines to a minimal intensity and then disappears from consciousness. This objection applies not only to Wundt's view of hallucinations, but also to H. Taine's explanation of them by the aid of his doctrine of "reductives," for this too identifies sensory vividness with intensity. (H. Taine, *De l'intelligence*, tome i. p. 108.)

Another widely current explanation is based on the view that the representation and the percept have their anatomical bases in different element-groups or "centres" of the brain, the "centre" of the representation being assigned to a higher level of the brain than that of the percept (the latter being sometimes assigned to the basal ganglia of the brain, the former to the cortex). It is then assumed that while the lower perceptual centre is normally excited only through the sense-organ, it may occasionally be excited by impulses playing down upon it from the corresponding centre of representation, when hallucination results.

This view also is far from satisfactory, because the great additions recently made to our knowledge of the brain tend very strongly to show that both sensations and memory-images have their anatomical bases in the same sensory areas of the cerebral cortex; and many considerations converge to show that their anatomical bases must be, in part at least, identical.

The views based on the assumptions of complete identity, and of complete separateness, of the anatomical bases of the percept

and of the representation are then alike untenable; and the alternative—that their anatomical bases are in part identical, in part different, which is indicated by this conclusion—renders possible a far more satisfactory doctrine. We have good reason to believe that the neural correlate of sensation is the transmission of the nervous impulse through a sensori-motor arc of the cortex, made up of a chain of neurones; and the view suggests itself that the neural correlate of the corresponding memory-image is the transmission of the impulse through a part only of this chain of cortical elements, either the efferent motor part of this chain or the afferent sensory part of it. Prof. W. James's theory of hallucinations is based on the latter assumption. He suggests that the sensory vividness of sensation and of the percept is due to the discharge of the excitement of the chain of elements in the forward or motor direction; and that, in the case of the image and of the representation, the discharge takes place, not in this direction through the efferent channel of the centre, but laterally into other centres of the cortex. Hallucination may then be conceived as caused by obstruction, or abnormally increased resistance, of the paths connecting such a cortical centre with others, so that, when it becomes excited in any way, the tension or potential of its charge rises, until discharge takes place in the motor direction through the efferent limbs of the sensori-motor arcs which constitute the centre.

It is a serious objection to this view that, as James himself, in common with most modern authors, maintains, every idea has its motor tendency which commonly, perhaps always, finds expression in some change of tension of muscles, and in many cases issues in actual movements. Now if we accept James's theory of hallucination, we should expect to find that whenever a representation issues in bodily action it should assume the sensory vividness of an hallucination; and this, of course, is not the case.

The alternative form of the view that assumes partial identity of the anatomical bases of the percept and the representation of an object, would regard the neural correlate of the sensation as the transmission of the nervous impulse throughout the length of the sensori-motor arc of the cortex, from sensory inlet to motor outlet; and that of the image as its transmission through the efferent part of this arc only; that is to say, in the case of the image, it would regard the excitement of the arc as being initiated at some point between its afferent inlet and its motor outlet, and as spreading, in accordance with the law of forward conduction, towards the motor outlet only, so that only the part of the arc distal or efferent to this point becomes excited.

This view of the neural basis of sensory vividness, which correlates the difference between the sensation and the image with the only known difference between their physiological conditions, namely the peripheral initiation of the one and the central initiation of the other, enables us to formulate a satisfactory theory of the physiology of hallucinations.

The anatomical basis of the perception and of the representation of any object is a functional system of nervous elements, comprising a number of sensori-motor arcs, whose excitement by impulses ascending to them by the sensory paths from the sense-organs determines sensations, and whose excitement in their efferent parts only determines the corresponding images. In the case of perception, some of these arcs are excited by impulses ascending from the sense-organs, others only by the spread of the excitement through the system from these peripherally excited arcs; while, in the case of the representation, all alike are excited by impulses that reach the system from other parts of the cortex and spread throughout its efferent parts only to its motor outlets.

If then impulses enter this system by any of the afferent limbs of its sensori-motor arcs, the presentation that accompanies its excitement will have sensory vividness and will be a true perception, an illusion, or an hallucination, according as these impulses have followed the normal course from the sense-organ, or have been diverted, to a lesser or greater degree, from their normal paths. If any such neural system becomes abnormally excitable, or becomes excited in any way with abnormal intensity, it is thereby rendered a path of exceptionally low-resistance capable of diverting to itself, from their normal path, any streams of

impulses ascending from the sense-organ; which ascending impulses, entering the system by its afferent inlets, excite sensations that impart to the presentation the character of sensory vividness; the presentation thus acquires the character of a percept in spite of the absence of the appropriate impression on the sense-organ, and we call it an hallucination.

This view renders intelligible the *modus operandi* of many of the predisposing causes of hallucination; e.g., the pre-occupation with certain representations of the ecstatic, or of the sufferer from delusions of persecution: the intense expectation of a particular sense impression, the generally increased excitability of the cortex in states of delirium; in all these conditions the abnormally intense excitement of the cortical systems may be supposed to give them an undue directive and attractive influence upon the streams of impulses ascending from the sense-organs, so that sensory impulses may be diverted from their normal paths. Again, it renders intelligible the part played by chronic irritation of a sense-organ, as when chronic irritation of the internal ear leads on to hallucinations of hearing; perhaps also the chronic irritation of sensory nerves that must accompany the states of visceral disease, shown by Head to be so frequently accompanied by a liability to hallucinations: for any such chronic irritation supplies a stream of disorderly impulses rising constantly from the sense-organ, for the reception of which the brain has no appropriate system, and which, therefore, readily enters any organized cortical system that at any moment constitutes a path of low-resistance. A similar explanation applies to the influence of fixed gazing upon a crystal, or the placing of a shell over the ear, in inducing visual and auditory hallucinations. The "recurrent sensations" experienced after prolonged occupation with some one kind of sensory object may be regarded as due to an abnormal excitability of the cortical system concerned, resulting from its unduly prolonged exercise. The hypothesis renders intelligible also the liability to hallucination of persons in the hysterical and hypnotic states, in whose brains the cortical neural systems are in a state of partial dissociation which renders possible an unduly intense and prolonged excitement of some one system at the expense of all other systems (*cf.* HYPNOTISM).

Coincidental Hallucinations.—It would seem that, in well-nigh all countries and in all ages, apparitions of persons known to be in distant places have been occasionally observed. Such appearances have usually been regarded as due to the presence, before the bodily eye of the seer, of the ghost, wraith, double or soul of the person who thus appears; and, since the soul has been very commonly supposed to leave the body, permanently at death and temporarily during sleep, trance or any period of unconsciousness, however induced, it was natural to regard such an appearance as evidence that the person whose wraith was thus seen was in some such condition. Such apparitions have probably played a part, second only to that of dreams, in generating the almost universal belief in the separability of soul and body.

In many parts of the world traditional belief has connected such apparitions more especially with the death of the person so appearing, the apparition being regarded as an indication that the person so appearing has recently died, is dying or is about to die. Since death is so much less common an event than sleep, trance, or other form of temporary unconsciousness, the wide extension of this belief suggests that such apparitions may coincide in time with death, with disproportionate frequency. The belief in the significance of such apparitions still survives in civilized communities, and stories of apparitions coinciding with the death of the person appearing are occasionally reported in the newspapers, or related as having recently occurred. The Society for Psychical Research has sought to find grounds for an answer to the question "Is there any sufficient justification for the belief in a causal relation between the apparition of a person at a place distant from his body and his death or other exceptional and momentous event in his experience?" The problem was attacked in a thoroughly scientific spirit, an extensive inquiry was made, and the results were presented and fully discussed in two large volumes, *Phantasms of the Living*, published in the year 1886, bearing on the title-page the names of Edmund Gurney,

F. W. H. Myers and F. Podmore. Of the three collaborators Gurney took the largest share in the planning of the work, in the collection of evidence, and in the elaboration and discussion of it.

Gurney set out with the presumption that apparitions, whether coincidental or not, are hallucinations in the sense defined above; that *they are false perceptions* and are not excited by any object or process of the external world acting upon the sense-organs of the percipient in normal fashion; that they do not imply the presence, in the place apparently occupied by them, of any wraith or any form of existence emanating from, or specially connected with, the person whose phantasm appears. This initial assumption was abundantly justified by an examination of a large number of cases for it, which showed that, in all important respects, most of these apparitions of persons at a distance, whether coincidental or not, were similar to other forms of hallucination.

The acceptance of this conclusion does not, however, imply a negative answer to the question formulated above. The Society for Psychical Research had accumulated an impressive and, to almost all those who had first-hand acquaintance with it, a convincing mass of experimental evidence of the reality of telepathy (*q.v.*), the influence of mind on mind otherwise than through the recognized channels of sense. The successful experiments had for the most part been made between persons in close proximity, in the same room or in adjoining rooms; but they seemed to show that the state of consciousness of one person may induce directly (*i.e.*, without the mediation of the organs of expression and sense-perception) a similar state of consciousness in another person, especially if the former, usually called the "agent," strongly desired or "willed" that this effect should be produced on the other person, the "percipient."

The question formulated above thus resolved itself for Gurney into the more definite form, "Can we find any good reason for believing that coincidental hallucinations are sometimes veridical, that the state of mind of a person at some great crisis of his experience may telepathically induce in the mind of some distant relative or friend an hallucinatory perception of himself?" It was at once obvious that, if coincidental apparitions can be proved to occur, this question can only be answered by a statistical inquiry; for each such coincidental hallucination, considered alone, may always be regarded as most educated persons of the present time have regarded them, namely, as merely accidental coincidences. That the coincidences are not merely accidental can only be proved by showing that they occur more frequently than the doctrine of chances would justify us in expecting. Now, the death of any person is a unique event, and the probability of its occurrence upon any particular day may be very simply calculated from the mortality statistics, if we assume that nothing is known of the individual's vitality. On the other hand, hallucinatory perceptions of persons, occurring to sane and healthy individuals in the fully waking state, are comparatively rare occurrences, whose frequency we may hope to determine by a statistical inquiry. If, then, we can obtain figures expressing the frequency of such hallucinations, we can deduce, by the help of the laws of chance, the proportion of such hallucinations that may be expected to coincide with (or, for the purposes of the inquiry, to fall within twelve hours of) the death of the person whose apparition appears, if no causal relation obtains between the coinciding events. If, then, it appears that the proportion of such coincidental hallucinations is greater than the laws of probability will account for, a certain presumption of a causal relation between the coinciding events is thereby established; and the greater the excess of such coincidences, the stronger does this presumption become. Gurney attempted a census of hallucinations in order to obtain data for this statistical treatment, and the results of it, embodied in *Phantasms of the Living*, were considered by the authors of that work to justify the belief that some coincidental hallucinations are veridical. In the year 1889 the Society for Psychical Research appointed a committee, under the chairmanship of the late Henry Sidgwick, to make a second census of hallucinations on a more extensive and systematic plan than the first, in order that the important conclusion reached by the authors of *Phantasms of the Living* might be put to the severer test rendered

possible by a larger and more carefully collected mass of data. Seventeen thousand adults returned answers to the question, "Have you ever, when believing yourself to be completely awake, had a vivid impression of seeing or being touched by a living being or inanimate object, or of hearing a voice; which impression, so far as you could discover, was not due to any external physical cause?" Rather more than two thousand persons answered affirmatively, and to each of these were addressed careful inquiries concerning their hallucinatory experiences. In this way it was found that of the total number, 381 apparitions of persons living at the moment (or not more than twelve hours dead) had been recognized by the percipients, and that, of these, 80 were alleged to have been experienced within twelve hours of the death of the person whose apparition had appeared. A careful review of all the facts, conditions and probabilities, led the committee to estimate that the former number should be enlarged to 1,300 in order to make ample allowance for forgetfulness and for all other causes that might have tended to prevent the registration of apparitions of this class. On the other hand, a severe criticism of the alleged death-coincidences led them to reduce the number, admitted by them for the purposes of their calculation, to 30. The making of these adjustments gives us about 1 in 43 as the proportion of coincidental death-apparitions to the total number of recognized apparitions among the 17,000 persons reached by the census. Now the death-rate being just over 19 per thousand, the probability that any person taken at random will die on a given day is about 1 in 19,000; or, more strictly speaking, the average probability that any person will die within any given period of twenty-four hours duration is about 1 in 19,000. Hence the probability that any other particular event, having no causal relation to his death, but occurring during his lifetime (or not later than twelve hours after his death) will fall within the same twenty-four hours as his death is 1 in 19,000; i.e., if an apparition of any individual is seen and recognized by any other person, the probability of its being experienced within twelve hours of that individual's death is 1 in 19,000, if no causal relation obtains between the two events. Therefore, of all recognized apparitions of living persons, 1 only in 19,000 may be expected to be a death-coincidence of this sort. But the census shows that of 1,300 recognized apparitions of living persons 30 are death-coincidences and that is equivalent to 440 in 19,000. Hence, of recognized hallucinations, those coinciding with death are 440 times more numerous than we should expect, if no causal relation obtained; therefore, if neither the data nor the reasoning can be destructively criticized, we are compelled to believe that some causal relation obtains; and, since good evidence of telepathic communication has been experimentally obtained, the least improbable explanation of these death-apparitions is that the dying person exerts upon his distant friend some telepathic influence which generates an hallucinatory perception of himself.

These death-coincidences constitute the main feature of the argument in favour of telepathic communication between distant persons, but the census of hallucinations afforded other data from which a variety of arguments, tending to support this conclusion, were drawn by the committee; of these the most important are the cases in which the hallucinatory percept embodied details that were connected with the person perceived and which could not have become known to the percipient by any normal means. The committee could not find in the results of the census any evidence sufficient to justify a belief that hallucinations may be due to telepathic influence exerted by personalities surviving the death of the body.

The critical handling of the cases by the committee seems to be above reproach. Those who do not accept their conclusion based on the death-coincidences must direct their criticism to the question of the reliability of the reports of these cases. It is to be noted that, although only those cases are reckoned in which the percipient had no cause to expect the death of the person whose apparition he experienced, and although, in nearly all the accepted cases, some record or communication of the hallucination was made before hearing of the death, yet in very few cases was any contemporary written record of the event

forthcoming for the inspection of the committee. (W. McD.)

HALLUIN, a frontier town of northern France, in the department of Nord, near the Lys, 14 m. N. by E. of Lille by rail. Pop. (1926) 11,012. The family of Halluin, which became extinct in the 14th century, is mentioned in the 13th century. Halluin has a Gothic church. The manufactures comprise linen and cotton goods, chairs and rubber goods, and brewing and tanning are carried on; there is a board of trade arbitration.

HALM, CARL FELIX (1809-1882), German classical scholar and critic, was born at Munich on April 5, 1809, and died there on Oct. 5, 1882. He is known chiefly as the editor of Cicero. He also edited a number of other classical texts for the Teubner series, the most important of which are Tacitus (4th ed., 1883); *Rhetores Latini minores* (1863); Quintilian (1868); Sulpicius Severus (1866); Minucius Felix together with Firmicus Maternus *De errore* (1867); Salvianus (1877) and Victor Vitensis's *Historia persecutionis Africanae provinciae* (1878).

See articles by W. Christ and G. Laubmann in *Allgemeine deutsche Biographie* and by C. Bursian in *Biographisches Jahrbuch*; and J. E. Sandys, *Hist. of Classical Scholarship*, iii, 195 (1908).

HALMA (Greek for "jump"), a table game, invented in 1883 by George H. Monks, of Boston, Massachusetts. It is played on a board divided into 256 squares, with wooden men resembling chess pawns. In the two-handed game 19 men are employed on each side, coloured respectively black and white; in the four-handed each player has 13, the men being coloured white, black, red and green. At the beginning of the game the men are drawn up in triangular formation in the enclosures, or yards, diagonally opposite each other in the corners of the board. The object of each player is to get all his men into his enemy's yard, the player winning who first accomplishes this. The moves are made alternately, the mode of progression being by a step, from one square to another immediately adjacent, or by a jump (whence the name) which is the jumping of a man from the square it occupies over the man just next to it, to an empty square just beyond. There may be two or more jumps in the same play, in case the situation admits it. This corresponds to jumping in draughts (checkers), except that in Halma, the hop may be in any direction, over friendly as well as hostile men, and the men jumped over are not taken but remain on the board.

See Hoffmann, *Card and Table Games* (London, 1903); R. F. Foster, *Foster's Complete Hoyle* (1928).

HALMAHEIRA ("great land"; also Jilolo or Gilolo), an island of the Dutch East Indies, belonging to the residency of Ternate, lying under the equator and about 128° E. Its shape is extremely irregular, resembling that of the island of Celebes. It consists of four peninsulas so arranged as to enclose three great bays (Kayu, Bicholi, Weda), all opening towards the east, the northern peninsula being connected with the others by an isthmus only 5 m. wide. On the western side of the isthmus lies another bay, that of Dodinga, in the mouth of which are situated the two islands Ternate and Tidore, whose political importance exceeds that of the larger island (see these articles). Of the four peninsulas of Halmaheira the northern and the southern are reckoned to the sultanate of Ternate, the north-eastern and south-eastern to that of Tidore; the former having 11, the latter three districts. The distance between the extremities of the northern and southern peninsulas, measured along the curve of the west coast, is about 240 m.; and the total area of the island is 6,500 sq.m. Knowledge of the island is very incomplete. It appears that the four peninsulas are traversed in the direction of their longitudinal axis by mountain chains 3,000 to 4,000 ft. high, covered with forests rich in a great variety of trees, without a central chain at the nucleus of the island whence the peninsulas diverge. The mountain chains, from which spurs extend to the coast, are frequently interrupted by plains, such as those of Weda and Kobi. The northern part of the mountain chain of the northern peninsula is volcanic, its volcanoes continuing the line of those of Makian, Ternate and Tidore. The mountains along the western coast are volcanic, and at least one, Gam Kenora (4,922 ft.), is active. Coral formations on heights in the interior would indicate oscillations of the land in several periods, but a detailed

geology of the island is wanting. There are numerous rivers, of which the chief are the Taliabu and the Kaili, but none are of great importance, and there are several lakes. Near Weda is a beautiful stalactite grotto—the Grotto of Sagea—which has been likened to the famous Blue Grotto of Capri. To the north-east of the northern peninsula is the considerable island of Morotai (635 sq.m.), which is more than 50 m. long and from 13 to 26 m. wide, with mountains reaching 3,000 ft. (the Sabotai range), and several rivers, and to the west of the southern peninsula the more important island of Bachian (*q.v.*) among others. Galela is a considerable settlement, situated on a bay of the same name on the north-east coast, in a well-cultivated plain which extends southward and inland. Vegetation is prolific. Rice is grown by the natives, but the sago tree is of far greater importance to them. Damsar is collected and coco-nuts are also grown, and the forests yield wild nutmeg and ironwood (*Nania vera*). The sea yields trepang and pearl shells. A little trade is carried on by the Chinese and Macassars of Ternate, who, crossing the narrow Isthmus of Dodinga, enter the Bay of Kayu on the east coast. The chief town is Patani, with probably not more than 2,000 inhabitants, and ports of call for vessels of the Royal Mail Packet Company are Galela, Tobela, Kayu, Weda and Patani, together with Wajibula in Morotai. The total population with Morotai is 102,340.

The inhabitants are mostly of immigrant Malayan stock. In the northern peninsula, which is the most thickly populated, are found people akin to the Papuan-Malay type, and a tribe around Galela who are Polynesian in physique, possibly remnants, much mixed by subsequent crossings with the Papuan indigenes, of the Caucasian hordes emigrating in prehistoric times across the Pacific. M. Achille Raffray gives a description of them in *Tour du Monde* (1879) where photographs will be found. "They are as unlike the Malays as we are, excelling them in tallness of stature and elegance of shape, and being perfectly distinguished by their oval face, with a fairly high and open brow, their aquiline nose and their horizontally placed eyes. Their beards are sometimes thick; their limbs are muscular; the colour of their skins is cinnamon brown. Spears of iron-wood, abundantly barbed, and small bows and bamboo arrows free from poison are their principal weapons." They are further described as having temples (*sabuas*) in which they suspend images of serpents and other monsters, as well as the trophies procured by war. They believe in a better life hereafter, but have no idea of a hell or a devil, their evil spirits only tormenting them in the present state.

The people in the Tidore part of the island, as the result of keen propaganda of the sultans of Tidore, are all Mohammedans, but in the Ternate division the aborigines are largely pagan. These people have crisp, wavy hair, a skin even lighter than that of the average Malay, and the men are strongly built and well made, though the women are thick-set and ugly. They are true forest people, some nomads, living only in shelters. A loin-cloth, with headdress, is their only covering. The sago and areca palm give them food and drink. They fish, hunt and cultivate the land in a simple style. Head-hunters in the past, they are a gentle and willing race now, but prone to violence from motives of revenge. Many indigenous dialects are spoken and on the coast Ternatan is largely used. Morotai has several Mohammedans and a few Christians among its population. The pagan people collect forest products and natives of Galelo in Halmahera visit Morotai to seek sago, and to fish.

The Portuguese and Spaniards were better acquainted with Halmahera than with many other parts of the archipelago; they sometimes called it Batu China, and sometimes Moro. It was circumnavigated by one of their vessels in 1525, and the general outline of the coasts is correctly given in their maps at a time when separate portions of Celebes, such as Macassar and Menado, are represented as distinct islands. The name (Jilolo) was really that of a native State, the sultan of which had the chief rank among the princes of the Moluccas before he was supplanted by the sultan of Ternate about 1380. His capital, Jilolo, lay on the west coast, on the first bay to the north of that of Dodinga. The Dutch obtained a footing in Halmahera with the aid of their

ally, the sultan of Ternate, and when they severed relations with this chief in 1683, the lands in Halmahera under the suzerainty of Ternate, came under Dutch influence, and by their treaty of 1660 with the sultan of Tidore, they had become overlords of all Tidorese fiefs, which opened up to them that part of Halmahera under Tidorese influence. In 1876 Danu Hassan, a descendant of the sultans of Jilolo, raised an insurrection in the island for the purpose of throwing off the authority of the sultans of Tidore and Ternate; and his efforts would probably have been successful but for the intervention of the Dutch. In 1878 a Dutch expedition was directed against the pirates in Tobolai, who were virtually extirpated.

HALMSTAD, a seaport of Sweden, chief town of the district (*län*) of Halland, on the east shore of the Cattegat, 76 m. S.S.E. of Gothenburg by the railway to Helsingborg. Pop. (1925) 23,171. Mention of the church of Halmstad occurs as early as 1462, and the fortifications are mentioned first in 1225. The latter were demolished in 1734. There were formerly Dominican and Franciscan monasteries in the town. The oldest town-privileges date from 1307 and it appears to have been frequently chosen as the meeting-place of the rulers and delegates of the three northern kingdoms. Under the union of Kalmar it was appointed to be the place for the election of a new Scandinavian monarch whenever necessary. Until 1660, when it was ceded to Sweden, the *län* of Halland formed part of the territory of Denmark in Sweden. The town lies at the mouth of the river Nissa, having a harbour (20 ft. depth) and roads giving safe anchorage. In the neighbourhood there are quarries of granite, which is exported chiefly to Germany. Other industries are engineering, shipbuilding and brewing, and there are cloth, jute, hat, wood-pulp and paper factories. The principal exports are granite, timber and matches; and butter through Helsingborg and Gothenburg. The imports are coal, machinery, manures, jute and cloth. Potatoes are largely grown in the district, and the salmon fisheries are valuable. The castle is the residence of the governor of the province. There are both mineral and sea-water baths in the neighbourhood.

HALO, in physical science a luminous circle, with various auxiliary features, surrounding the sun or moon. The word is derived from the Greek *ἅλως*, a threshing-floor and used to denote the disc of the sun or moon, probably on account of the circular path traced out by the oxen threshing the corn. It was later used for any luminous ring, such as that encircling the sun or moon, or portrayed about the heads of saints.

A halo is caused by the ice-crystals in the atmosphere producing reflection and refraction of the light. The optical phenomena produced by atmospheric water and ice may be classified according to the relative positions of the luminous ring and the source of light. *Halos* and *coronae*, or "glories," encircle the luminary; *rainbows*, *fog-bows*, *mist-halos*, *anthelia* and *mountain-spectres* have their centres at the anti-solar point. Halos are at definite distances (22° and 46°) from the centre of illumination, and when coloured have red on the *inside*, being caused by refraction; coronae surround the sun at variable distances but always nearer than 22° and the red colour appears on the *outside*—the result of diffraction.

Coronae are of frequent occurrence, but the halo, particularly of well-developed form, is rare except in polar regions. Here they attain great brilliance and complexity. (For illustrations of various types of halos see Met. Office *Observer's Handbook*.) The phenomenon of a halo, solar or lunar, as seen from the earth, is represented in fig. 1; fig. 2 is a diagrammatic sketch showing the appearance as viewed from the zenith; though only in very exceptional circumstances are all the parts visible. Encircling the luminary (S), are two circles, the "inner halo" (I) and the "outer halo" (O), having radii of about 22° and 46°, and usually exhibiting confused spectrum colours with a decided red tint on the inside. Passing through the luminary and parallel to the horizon, there is a luminous white ring, the *parhelic circle* (P), on which a number of images of the sun or moon appear (four of these are indicated on the figures by means of the letter *p*) but the images at 46° are very rare. The most brilliant are situated at the intersections of the inner halo and the parhelic circle and are known

as *parhelia*, or "mock-suns" (Gr. παρά, beside, and ἥλιος, the sun), or as *paraslenae*, "mock-moons" (Gr. σελήνη, the moon). The parhelia are most brilliant when the sun is low; as it rises they pass slightly outside the halo and exhibit flaming tails. The other images on the parhelic circle are the *parantheia* (*q*) and the *anthelion* (*a*) (Gr. ἀντί, opposite). Paranthelia are situated at from 90° to 140° of parhelic arc from the sun while the anthelion is at

FIG. 1.—PHENOMENON OF A HALO, SOLAR OR LUNAR, AS SEEN FROM THE EARTH. FIG. 2.—SHOWING THE APPEARANCE AS VIEWED FROM THE ZENITH. SEE TEXT FOR REFERENCES

the anti-solar point and is a patch of white light often exceeding in size the apparent diameter of the sun. From the parhelia of the inner halo two arcs (L) curve towards the outer halo. These "arcs of Lowitz" were first described in 1794 by Johann Tobias Lowitz (1757–1804). Arcs (T), tangential to the visible upper and lower parts of each halo, also occur, and in the case of the inner halo they may be prolonged and joined to form a luminous closed curve, quasi-elliptical in shape.

The explanation of halos originated with René Descartes, who correctly ascribed their formation to the effects of ice-crystals. This theory was adopted by Edmé Mariotte, Henry Cavendish and Thomas Young, who explained the various parts of the halo, though sometimes in a somewhat arbitrary manner. Subsequently J. G. Galle and A. Bravais completely demonstrated the general validity of the theory. Bravais' memoir, published in the *Journal de l'École royale polytechnique* (1847), still ranks as the classic on halos.

Ice-crystals exist only in high clouds; the type usually associated with halos is the cirro-nebula. In this the normal form of ice-crystal is an upright hexagonal prism either elongated as a needle or flattened like a thin plate. Three refracting angles become possible: 120° between two adjacent prism faces, 60° between two alternate prism faces, and 90° between a prism face and the base. If innumerable numbers of such crystals fall in any manner between the observer and the sun, there will always be some prisms whose alternate faces are traversed by a ray of light, and this would be refracted. Mariotte showed that the inner halo represented by the crowding together of refracted rays is the position of minimum deviation. This approximately equals the minimum deviation (22°) produced by an ice prism whose refractory angle is 60° . As the angle of minimum deviation is smaller for the less refrangible red rays than for the violet, the halo will be coloured red on the inside. Henry Cavendish similarly explained the halo of 46° as being the result of refraction by faces inclined at 90° . The impurity of the colours, chiefly consequent on oblique refraction, results in a well-marked red tint with but mere traces of green and blue, while the external ring of each halo is nearly white; the 46° halo is broader and less luminous.

The two halos admit of explanation without assigning any particular arrangement to the ice-crystals. Nevertheless, certain distributions will predominate, for the crystals will tend to fall so as to offer the least resistance to their motion, a needle-shaped crystal tending to keep its axis vertical, a plate-shaped crystal to keep its axis horizontal. Young explained the parhelic circle as caused by reflection from the vertical faces of the long prisms

and the bases of the short ones. If the vertical faces become very numerous, the eye will perceive a white horizontal circle. Reflection from an excess of horizontal faces gives rise to a luminous vertical circle passing through the sun, but this appearance is of infrequent occurrence.

The parhelia, according to Mariotte, are caused by refraction through a pair of alternate faces of a vertical prism. When the sun is on horizon the rays fall upon the principal section of the prisms; the minimum deviation for such rays is 22° , and consequently the parhelia are not only on the inner halo, but also on the parhelic circle. As the sun rises, the rays enter the prisms more and more obliquely, and the angle of minimum deviation increases; but, since the emergent ray and the incident ray make the same angle with the refracting edge, the parhelia will remain on the parhelic circle, but gradually recede from the inner halo. The different values of the angle of minimum deviation for differently coloured rays will give rise to spectrum colours, the red being nearest the sun, while farther away the overlapping of the spectra produces a long luminous white tail sometimes extending for a space of nearly 20° . The "arcs of Lowitz" have been explained by Galle and Bravais as consequent on small oscillations of the vertical prisms, but the theory has only been imperfectly verified.

The tangential arcs were explained by Young as being caused by thin plates with their axes horizontal, refraction taking place through alternate faces. If there are many of these plates then their axes will lie in all possible horizontal directions and consequently give rise to a continuous series of parhelia which touch externally in the inner halo, both above and below, and under certain conditions (such as the requisite altitude of the sun) form two closed elliptical curves; generally, however, only the upper and lower portions are seen. The tangential arcs to the halo of 46° are due to refraction through faces inclined at 90° ; these arcs occur more frequently and are of greater brilliance than the 22° arcs.

The *parantheia* (*a*) may be caused by two internal or two external reflections. A pair of equilateral triangular prisms having a common face, or a stellate crystal formed by the symmetrical interpenetration of two equilateral triangular prisms, permits of two internal reflections by faces inclined at 120° (producing a total deviation of 240°), and so gives rise to two white images of the sun each at an angular distance of 120° from it. Double internal reflection by an equilateral triangular prism would form a single coloured image on the parhelic circle at about 98° from the sun. The 120° and 98° angular distances result only when the sun is on the horizon; they increase as it rises.

The *anthelion* may be explained as being caused by two internal reflections of the solar rays by a hexagonal lamellar prism of ice having its axis horizontal and one of the diagonals of its base vertical. The emerging rays are parallel to their original direction and form a bright patch of light on the parhelic circle diametrically opposite to the sun. (See also MIRAGE.)

HALOGENS. This term is applied to fluorine, chlorine, bromine and iodine, on account of the great similarity of their sodium salts to ordinary sea-salt (Gr. ἅλς, salt, and γεννᾶν, to produce). These four elements show a great resemblance to one another in their general chemical behaviour, and in that of their compounds, whilst their physical properties show a gradual transition. Thus, as the atomic weight increases, the state of aggregation under ordinary conditions changes from that of a gas in the case of fluorine and chlorine, to that of a liquid (bromine) and finally to that of the solid (iodine). The halogen of lower atomic weight can displace one of higher atomic weight from its hydrogen compound, or from the salt derived from such hydrogen compound, while, on the other hand, the halogen of higher atomic weight can displace that of lower atomic weight, from the halogen oxy-acids and their salts; thus iodine will liberate chlorine from potassium chlorate, and also from perchloric acid. All four of the halogens unite with hydrogen, but the affinity for hydrogen decreases as the atomic weight increases, hydrogen and fluorine uniting explosively at very low temperatures (even at -253° , where all other chemical action has apparently ceased), and in

the dark, whilst hydrogen and iodine unite only with difficulty and even then the resulting compound is very readily decomposed by heat. The hydrides of the halogens are all colourless, strongly fuming gases, readily soluble in water to give a strongly acid solution: they react readily with basic oxides, forming in most cases well-defined crystalline salts which resemble one another very strongly. On the other hand the stability of the known oxygen compounds increases with the atomic weight; thus iodine pentoxide is, at ordinary temperatures, a well-defined crystalline solid, which is decomposed only when heated strongly, whilst chlorine monoxide, chlorine peroxide, and chlorine heptoxide are unstable, even at ordinary temperatures, decomposing at the slightest shock. Binary compounds of bromine and oxygen have not yet been isolated. In some respects there is a very marked difference between fluorine and the other members of the group, for, whilst sodium chloride, bromide and iodide are readily soluble in water, sodium fluoride is much less soluble; again, silver chloride, bromide and iodide are practically insoluble in water, whilst, on the other hand, silver fluoride is appreciably soluble in water. Further, although calcium fluoride is practically insoluble in water, the other halides of calcium are very soluble. Again, fluorine shows a great tendency to form double salts which have no counterpart among the compounds formed by the other members of the family.

All four halogens apparently possess seven valency electrons, and by combination they strive to obtain the stable 8-electron grouping, thereby becoming negatively charged.

HALOPHYTES, a general name used in botany to denote plants growing in salt marshes and similar environments with a high salt content. Such plants show adaptations for conservation of water. (See PLANTS: *Ecology*; *XEROPHYTE*.)

HALPHEN, LOUIS (1880–), French historian, was born in Paris on Feb. 4, 1880. He was educated at Versailles and in Paris, and since 1910 has been professor at Bordeaux. His chief publications are, *Le Comté d'Anjou au XI^e siècle* (1906), *Etudes sur l'administration de Rome au Moyen Age* (1907); *Paris sous les premiers Capétiens 987–1223* (1909); *Le règne de Charles le Chauve* (1909, with F. Lot); *L'histoire en France depuis cent ans* (1914); *Etudes critiques sur l'histoire de Charlemagne* (1921) and an edition with translation of the Life of Charlemagne by Eginhardus (1923). Halphen has also directed several series, the most recent being *Peuples et civilisation, histoire générale depuis l'antiquité jusqu'à nos jours* (1925 seq.).

HALS, FRANS (1580?–1666), Dutch painter, was born at Antwerp according to the most recent authorities in 1580 or 1581, and died at Haarlem in 1666. As a portrait painter second only to Rembrandt in Holland, he displayed extraordinary talent and quickness in the exercise of his art coupled with improvidence in the use of the means which that art secured to him. He brought up and supported a family of ten children with success till 1652, when the forced sale of his pictures and furniture, at the suit of a baker to whom he was indebted for bread and money, brought him to absolute penury. The inventory of the property seized on this occasion only mentions three mattresses and bolsters, an armoire, a table and five pictures. This humble list represents all his worldly possessions at the time of his bankruptcy. Subsequently to this he was reduced to still greater straits, and his rent and firing were paid by the municipality, which afterwards gave him (1664) an annuity of 200 florins. We may admire the spirit which enabled him to produce some of his most striking works in his unhappy circumstances. Hals's pictures illustrate the various strata of society into which his misfortunes led him. His banquets or meetings of officers, of sharpshooters, and gildsmen are the most interesting of his works. But they are not more characteristic than his low-life pictures of itinerant players and singers. His portraits of gentlefolk are true and noble, but hardly so expressive as those of fishwives and tavern heroes. His first master at Antwerp was probably van Noort, as has been suggested by M. G. S. Davies, but on his removal to Haarlem Frans Hals entered the atelier of van Mander, the painter and historian, of whom he possessed some pictures which went to pay the debt of the baker already alluded to.

In every form of his art we can distinguish his earlier style from

that of later years. It is curious that we have no record of any work produced by him in the first decade of his independent activity, save an engraving by Jan van de Velde after a lost portrait of "The Minister Johannes Bogardus," who died in 1614. The earliest works by Frans Hals that have come down to us, "Two Boys Playing and Singing" in the gallery of Cassel, and a "Banquet of the officers of the 'St. Joris Doele'" or Arquebusiers of St. George (1616) in the museum of Haarlem, exhibit him as a careful draughtsman capable of great finish, yet spirited withal. His flesh, less clear than it afterwards becomes, is pastose and burnished. Later he becomes more effective, displays more freedom of hand, and a greater command of effect. At this period we note the beautiful full-length of "Madame van Beresteyn" at the Louvre in Paris, and a splendid full-length portrait of "Willem van Heythuysen" leaning on a sword in the Liechtenstein collection at Vienna. Both these pictures are equalled by the other "Banquet of the officers of the Arquebusiers of St. George" (with different portraits) and the "Banquet of the officers of the 'Cloveniers Doelen'" or Arquebusiers of St. Andrew of 1627 and an "Assembly of the officers of the Arquebusiers of St. Andrew" of 1633 in the Haarlem Museum. A picture of the same kind in the town hall of Amsterdam, with the date of 1637, suggests some study of the masterpieces of Rembrandt, and a similar influence is apparent in a picture of 1641 at Haarlem, representing the "Regents of the Company of St. Elizabeth" and in the portrait of "Maria Voogt" at Amsterdam. But Rembrandt's example did not create a lasting impression on Hals. He gradually dropped more and more into grey and silvery harmonies of tone; and two of his canvases, executed in 1664, "The Regents and Regentesses of the Oudemanshuis" at Haarlem, are masterpieces of colour, though in substance all but monochromes. In fact, ever since 1641 Hals had shown a tendency to restrict the gamut of his palette, and to suggest colour rather than express it. This is particularly noticeable in his flesh tints which from year to year became more grey, until finally the shadows were painted in almost absolute black, as in the "Tymane Oosdorp," of the Berlin Gallery. As this tendency coincides with the period of his poverty, it has been suggested that one of the reasons, if not the only reason, of his predilection for black and white pigment was the cheapness of these colours as compared with the costly lakes and carmines.

As a portrait painter Frans Hals had scarcely the psychological insight of a Rembrandt or Velazquez, though in a few works, like the "Admiral de Ruyter," in Earl Spencer's collection, the "Jacob Olycan" at the Hague Gallery, and the "Albert van der Meer" at Haarlem town hall, he reveals a searching analysis of character which has little in common with the instantaneous expression of his so-called "character" portraits. In these he generally sets upon the canvas the fleeting aspect of the various stages of merriment, from the subtle, half ironic smile that quivers round the lips of the curiously misnamed "Laughing Cavalier" in the Wallace Collection to the imbecile grin of the "Hille Bobbe" in the Berlin Museum.

Though a visit to Haarlem town hall, which contains the five enormous Doelen groups and the two Regenten pictures, is as necessary for the student of Hals's art as a visit to the Prado in Madrid is for the student of Velazquez, good examples of the Dutch master have found their way into most of the leading public and private collections. In the British isles, besides the works already mentioned, portraits from his brush are to be found at the National Gallery, the Edinburgh Gallery, the Glasgow Corporation Gallery, Hampton Court, Buckingham Palace, Devonshire House, the collections of Lord Northbrooke, Lord Ellesmere and Lord Spencer and in the Lord Iveagh bequest at Kenwood House. At Amsterdam is the celebrated "Flute Player," once in the Dupper collection at Dort; at Brussels, the patrician "Heythuysen"; at the Louvre, "Descartes"; at Dresden, the painter "Van der Vinne." Hals's sitters were taken from every class of society—admirals, generals and burgomasters pairing with merchants, lawyers, clerks. To register all that we find in public galleries would involve much space. There are eight portraits at Berlin, six at Cassel, five at St. Petersburg, six at the Louvre, two at Brussels, five at Dresden, two at Gotha. In private collections, chiefly in Paris, Haarlem and

Vienna, we find an equally important number.

For two centuries after his death Frans Hals was held in such poor esteem that some of his paintings, which are now among the proudest possessions of public galleries, were sold at auction.

The earliest record of a sale of a Frans Hals in Great Britain is that of 1769 when "A Music Conversation" was bought from the Schaub Collection for £28 by Lord Byron. The portrait of "Johannes Aeronius" now at the Berlin Museum realized five shillings at a sale in 1786. In 1885, £1,000 was still considered a very high price for a work by the master; but in 1913 a picture by him only 11 in. x 8 in., "Portrait of a Lady," fetched £5,985, while in 1908 the fine large family group from the collection of Lord Talbot of Malahide was acquired by the National Gallery for £25,000. The outcry at the time against this high price has since proved unworthy, for in 1919 at the Drummond sale a much smaller picture, "Portrait of Cozmans," made as much as £26,775. Of the master's numerous family none has left a name except FRANS HALS THE YOUNGER, born about 1622, who died in 1669. His pictures represent cottages and poultry; and the "Vanitas" at Berlin, a table laden with gold and silver dishes, cups, glasses and books, is one of his finest works and deserving of a passing glance.

Quite in another form, and with much of the freedom of the elder Hals, DIRK HALS, his brother (born at Haarlem, died 1656), is a painter of festivals and ball-rooms. But Dirk had too much of the freedom and too little of the skill in drawing which characterized his brother. He remains second on his own ground to Palamedes. A fair specimen of his art is a "Lady playing a Harpsichord to a Young Girl and her Lover" in the van der Hoop collection at Amsterdam, now in the Ryks Museum. More characteristic, but not better, is a large company of gentle-folk rising from dinner, in the Academy at Vienna.

Vosmaer, *Etchings after Frans Hals* (Leyden, 1873); Percy Rendell Head, *Sir Anthony Van Dyck and Frans Hals* (London, 1879); D. Knackfuss, *Frans Hals* (Leipzig, 1896); G. S. Davies, *Frans Hals* (London, 1902). W. Bode and M. Binder, *Franz Hals, sein Leben und seine Werke* (Berlin, 1914).

HALSBURY, HARDINGE STANLEY GIFFARD, 1ST EARL OF (1823-1921), English lord chancellor, son of Stanley Lees Giffard, LL.D., was born in London on Sept. 3, 1823. He was educated at Merton college, Oxford, and was called to the bar at the Inner Temple in 1850, joining the North Wales and Chester Circuit. Afterwards he had a large practice at the central criminal court and the Middlesex sessions, and he was for several years junior prosecuting counsel to the Treasury. He was engaged in most of the celebrated trials of his time, including the Overend and Gurney and the Tichborne cases. He became queen's counsel in 1865, and a bencher of the Inner Temple. Giffard twice contested Cardiff in the Conservative interest, in 1868 and 1874, but he was still without a seat in the House of Commons when he was appointed solicitor-general by Disraeli in 1875 and received the honour of knighthood. In 1877 he succeeded in obtaining a seat, when he was returned for Launceston, which borough he continued to represent until his elevation to the peerage in 1885. He was then created Baron Halsbury and appointed lord chancellor, thus forming an exception to the rule that no criminal lawyer ever reaches the woolsack. Lord Halsbury resumed the position in 1886 and held it until 1892 and again from 1895 to 1905, his tenure of the office, broken only by the brief Liberal ministries of 1886 and 1892-95, being longer than that of any lord chancellor since Lord Eldon. In 1898 he was created earl of Halsbury and Viscount Tiverton. Among Conservative lord chancellors Lord Halsbury must always hold a high place, his grasp of legal principles and mastery in applying them being pre-eminent among the judges of his day. He died in London on Dec. 11, 1921.

HALSEY, SIR LIONEL (1872-), G.C.V.O. (1920), K.C.I.E. (1922), G.C.M.G. (1925), British admiral, was born on Feb. 26, 1872, son of the Rt. Hon. Sir Frederick Halsey of Gadesden. He was educated at Stubbington House, Fareham. He entered the navy, joining H.M.S. Britannia in 1885, and was one of those who served in the defence of Ladysmith (1899-1900). For his services in the defence he was promoted commander in

1901. He was promoted captain (1905), and after the outbreak of the World War was in command of H.M.S. "New Zealand" in the actions in the Heligoland fight (1914), and at the Dogger Bank (1915). At the battle of Jutland he served in H.M.S. "Iron Duke." In 1917 he was promoted rear-admiral, and appointed third sea lord, and from 1918 to 1919 commanded the Royal Australian navy. He acted as chief of staff to the Prince of Wales during his tours in Canada (1919), Australia and New Zealand (1920) and India and Japan (1921-22), being promoted vice-admiral in 1921. He retired in 1922, and was given the rank of admiral in 1926. In 1920 he was appointed comptroller and treasurer to the Prince of Wales.

HALSTEAD, a market-town added to the borough of Harwich in 1917, in the Harwich parliamentary division of Essex, England, on the Colne, 17 m. N.N.E. from Chelmsford. Pop. (1921) 5,923. The church of St. Andrew is mainly Perpendicular. The grammar school dates from 1594. There are large silk and crape works. Two miles north of Halstead is Little Maplestead, where the church is the latest in date of the four churches with round naves extant in England, being of 12th-century foundation, but showing early Decorated work. The chancel, which is without aisles, terminates in an apse. Three m. N.W. from Halstead are the large villages of Sible Hedingham and Castle Hedingham. At the second is the Norman keep of the De Veres, of whom Aubrey de Vere held the lordship from William I. The keep dates from the end of the 11th century, and exhibits much Norman work. The church of St. Nicholas, Castle Hedingham, is Norman, Transitional and Early English.

HALT. Lame, crippled; also a verb meaning to limp. "String-halt" or "spring-halt" is a nervous disorder affecting the muscles of the hind legs of horses.

HALUNTUM, an ancient city of Sicily (Gr. Ἀλόντιον, mod. S. Marco d'Alunzio), 6 m. from the north coast and 25 m. E.N.E. of Halaesa. It was probably of Sicel origin, though its foundation was ascribed to some of the companions of Aeneas. It suffered considerably at the hands of Verres. The abandoned church of S. Mark, just outside the modern town, is built into the cella of an ancient Greek temple, which measures 62 ft. by 18.

HALYBURTON, JAMES (1518-1589), Scottish reformer, was one of the lords of the congregation in 1557, and commanded the contingents sent by Forfar and Fife against the queen regent in 1559. He took part in the defence of Edinburgh, and in the battles of Langside (1568) and Restalrig (1571), where he was captured by Mary's troops. He represented Morton at the conference of 1578, and was one of the royal commissioners to the General Assembly in 1582 and again in 1588.

HALYBURTON, THOMAS (1674-1712), Scottish divine, was born at Dupplin, near Perth, on Dec. 25, 1674. His father, one of the ejected ministers, having died in 1682, he was taken by his mother in 1685 to Rotterdam to escape persecution. In 1696 he graduated at the University of St. Andrews and in 1700 he was ordained minister of the parish of Ceres. In 1710 he became professor of theology in St. Leonard's college, St. Andrews. He died from the effects of overwork in 1712.

The works by which he continues to be known were all of them published after his death. Wesley and Whitefield were accustomed to commend them to their followers. They were published as follows: *Natural Religion Insufficient, and Revealed Religion Necessary, to Man's Happiness in his Present State* (1714), an able statement of the orthodox Calvinistic criticism of the deism of Lord Herbert of Cherbury and Charles Blount; *Memoirs of the Life of Mr. Thomas Halyburton* (1715), three parts by his own hand, the fourth from his diary by another hand; *The Great Concern of Salvation* (1721), with a word of commendation by I. Watts; *Ten Sermons Preached Before and After the Lord's Supper* (1722); *The Unpardonable Sin Against the Holy Ghost* (1784).

HAM is the name of Noah's second son. It is true that, contrary to the prevailing tradition, he appears in Gen. ix. 24 as the youngest of Noah's three sons, but close examination of this story makes it clear that here the name Ham has replaced an original Canaan. The table of nations in Gen. x. represents Ham as the ancestor of Cush (=Ethiopia), Mizraim (=Egypt), Put, and Canaan, that is, of the original inhabitants of Palestine and the peoples to the south-west. Ham appears also as a place-name

Gen. xiv. 5, and as the designation of a people or place, 1 Chron. iv. 40; both references are obscure. See the *Cambridge Ancient History*, vol. 1, p. 184 *seq.*

HAM, a small town of northern France, in the department of Somme, 36 m. E.S.E. of Amiens on the Northern railway between that city and Laon. Pop. (1906) 2,786. It stands on the Somme, dominated by a castle which was built in the 10th century, now in ruins. The castle of Ham has frequently been used as a state prison both in ancient and modern times, and the list of prisoners include Joan of Arc, Louis of Bourbon, the ministers of Charles X., Louis Napoleon, and Generals Cavaignac and Lamoricière. During 1870-1871 Ham was several times captured and recaptured by the belligerents. From the 9th century onwards it was the seat of a lordship which, after the extinction of its hereditary line, passed in succession to the houses of Coucy, Enghien, Luxembourg, Rohan, Vendôme and Navarre, and was finally united to the French crown on the accession of Henry IV. The church, damaged during the war 1914-1918, includes 12th century effigies of the Lords of Ham in its ancient crypt. Ham is at an important position on the Somme and suffered greatly during the campaign on the Western front in 1914-1918, especially during the retreat in the spring of 1917. It was in this vicinity that tanks were first used.

HAM. The thigh and hind leg of a pig is termed the gammon, but when cut from the carcase and separately cured it is termed the ham. As in the case of bacon (*q.v.*) there are different methods of curing, but the variety of methods by which hams are cured is much larger. When home curing of bacon and hams in farm houses was common every housewife had her own special recipe for pickling, curing and, generally, smoking hams. Now that the operation is done commercially on a large scale there is general uniformity of system. One or two special methods of curing have established a trade in a particular kind and quality of ham. Among them are the York ham in England, the Brandenburg ham in Germany, and the peach-fed ham in America.

No statistics are available of the production of hams but the quantity and value imported into Great Britain and Northern Ireland are ascertainable from the trade accounts. Practically the whole of the imports come from Canada and the United States. The following were the imports in 1927, the pre-war average being added for comparison:

Great Britain: Imports of Ham

	1927		1909-13	
	Quantity	Value	Quantity	Value
	Cwts.	£	Cwts.	£
U.S.A.	716,104	3,718,803	841,442	2,637,361
Canada	133,703	715,216	63,623	211,610
Other countries	52,729	275,835	6,102	22,173
	902,536	4,709,854	911,167	2,871,144

It is noteworthy that while the importation of hams into Great Britain is less than in 1909-13 that of bacon has increased by about 4 million cwt. The reduction has been especially marked since 1923 when 1½ million cwt. of hams were imported. It appears probable that there has been an increase in British home production, but no statistical evidence can be cited in proof of this fact.

(R. H. R.)

United States.—In the United States the term "ham" is applied to the fresh or cured thigh of the hog. The hams are cut from the rest of the side, trimmed and cured in a pickle made of salt, sugar and a nitrate or nitrite. After pickling and soaking, the ham is smoked with fumes from hard-wood or from sawdust. Hams also are sold and consumed to some extent in the fresh state.

Production.—The production of ham in the United States runs into millions of pounds annually. An average hog will yield approximately 13% of its live weight in ham. Figuring an estimated average weight of 14 lb. per ham, the production of hams in the United States, both fresh and cured, probably exceeds 1,600,000 lb. annually. (This includes farm production.)

Exports of Ham.—Exports of ham and bacon from the United States during the period from 1910 to 1913 ranged from approximately 150,000,000 lb. to 200,000,000 pounds. In 1927, exports of hams and shoulders totalled 122,613,240 lb., valued at approximately \$25,319,569. During the World War, exports of hams greatly increased. During one year they reached the total of approximately three quarters of a billion pounds. Most of the hams exported from the United States are sent to the United Kingdom. A few are shipped to the Netherlands, France and Belgium and also to Central and South American countries.

Marketing.—After smoking, the ham is chilled and then wrapped in a grease-proof paper, then in an absorbent paper, and finally in an attractively coloured and printed parchment paper covering for sale in the retail meat shop. Some hams are sold unwrapped but practically all hams are branded on the skin side with a trademark.

As is the case with bacon, both fresh and cured hams are traded in extensively on the Chicago Board of Trade and also are sold by one packer to another. Most trading is done in carload lots. The processing and marketing of hams is handled at many points in much the same way as bacon (*q.v.*).

The practice of skinning hams at the point of production is growing in the United States. Skinning involves removal of the skin and sometimes portions of the fat from the upper part of the ham.

Uses and Food Value of Ham.—Ham is one of the most popular dishes in the American dietary. This undoubtedly is due to the fact that it is very palatable and that it may be prepared easily in a variety of ways. The whole or half ham and the butt and shank may be baked or boiled; slices may be broiled or fried. It is also used extensively as a sandwich meat. From nutritional and other standpoints, ham offers some rather obvious reasons for being popular. Fresh meats must be consumed within a short space of time; cured meats can be kept in good condition for great lengths of time. Again, ham offers a pleasing contrast in flavour to fresh meats.

Besides the points just enumerated, there is the additional virtue that ham is one of the products of a very economical meat-producing animal. The hog is one of the most economical of all food-producing animals when measured in terms of the yield received from a given outlay of feed consumed by the animal. Ham is one of the most nutritious of meat foods. It furnishes large quantities of the highest quality protein. Proteins differ in their value as food for human beings according to the kind and amount of the various smaller chemical compounds, known as amino acids, of which they are constituted. As a rule, animal proteins are superior to vegetable proteins in this respect. The flesh of meat-producing animals—and this includes ham—is one of the best sources of this protein.

Readily available energy is also supplied by ham. The amount depends upon the fatness of the ham and upon the relative amount of this fat eaten. For example, lean ham may furnish about 1,200 calories and fat ham may furnish as much as 2,600 calories per pound of substance eaten. Ham is a good source of many of the mineral elements needed for adequate nutrition. Many of these mineral elements are furnished in adequate amounts in any usual diet. Those most apt to be deficient are, in the relative order of their importance: calcium, iron, iodine and phosphorus. Ham, along with muscle meats in general, is a good source of iron and phosphorus. The iodine content will depend upon whether the hog has been fed on crops grown on land that has not had its store of iodine depleted. The supply of calcium in ham is rather small.

As a source of the vitamins, ham qualifies for a place on the menu. Its content of vitamin A may be quite low, but it also may be high if the animal from which it came has been fed on feeds rich in this vitamin. According to the work of investigators in the U.S. Department of Agriculture, lean pork is an important source of vitamin B and compares rather favourably with such excellent vitamin foods as liver and kidney. Even when the pork is cured, smoked and cooked its content of this vitamin is high. Ham, therefore, is a good source of vitamin B.

Since ham is not eaten unless it is well cooked, it can not be counted as a source of vitamin C. However, it is rich in both the pellagra-preventing vitamin (G) and the vitamin needed for the normal functioning of the reproductive process in animals (vitamin E).

(W. HA.)

HAMA, an ancient Hittite city, built on both banks of the Orontes, now a centre of commerce for the Bedouin: pop. 51,000 (about 6,000 Christians). The citadel hill, which is partly artificial, rises to a height of about 130 feet. European competition has seriously affected the silk, woollen and cotton manufactures for which the city was formerly noted. It has connection by rail through Aleppo with the Constantinople-Baghdad railway on the north, and through Homs with the Beirut-Damascus railway on the south. Interesting and peculiar to Hama are the vast water wheels (*na'ura*) which raise the water to the higher levels for irrigation. In the 14th century there were over 30 of these wheels; now only nine.

History.—Hama was an early Hittite settlement and is the most southerly place where Hittite inscriptions have been found. Lying athwart the Assyrian road to the west lands it fell a prey to Shalmanassar II. (854 and 849 B.C.) to Tiglath Pileser III. (738 B.C.), and to Sargon (720 B.C.). According to 2 Kings, xvii., 24, a portion of its inhabitants was transported to northern Israel.

In the Hellenistic period Hama received the name Epiphania in honour of Antiochus (iv.) Epiphanes. It surrendered to the Mohammedans (A.D. 638) and its Christian basilica was transformed into a mosque (the Great Mosque). It was captured by the Crusaders (1108), retaken by the Mohammedans (1115), and occupied by Saladin (1187). During the 12th century it suffered severely from earthquakes. The famous Arab geographer, Abu'l-Fida (14th century), was its prince and under him the city enjoyed great prosperity.

(E. Ro.)

HAMADAN, a province and town of Persia. The province is bounded north by Kazvin and Khamseh, west by Kermanshah, south by Malayer and Iraq and east by Tehran provinces. It has many well watered plains producing much grain. Before the World War there were extensive plantations of trees but much timber was cut down during the Turkish occupation. The population is estimated at 350,000, more than one half being Turkistanis of the Karaguzlu (now a quite sedentary people) and Shamlu tribes. The revenue in 1926-27 amounted to 5,560,429 krans.

Hamadan the chief town of the province is situated some 180 m. W.S.W. of Tehran, on the Kazvin-Kermanshah motor road, at an elevation of over 6,000 ft., near the foot of the Mount Alvand, whose granite peak has an altitude of 11,900 feet. It is one of the principal trade and distributing centres of Persia, being at the meeting point of a number of roads, some of which, including that to Sultanabad, were made passable for motor traffic during and after the World War. The population was estimated in 1919 at 70,000, of whom one-fourth were Turks or of Turkish origin, the remainder being Persians, Jews (some 4,000) with a sprinkling of Armenians. The bazars are extensive and well stocked, but the streets of the town are narrow and tortuous. Hamadan is the seat of the leather, shell-lac and gall-nut trade of Persia, and a centre of the important rug industry. An authority states that one-eighth of the population lives and works in the tanneries, and hides are imported from all over Persia. The climate of Hamadan is described as pleasant; but the winters are long and severe with heavy falls of snow.

Hamadan is the Ecbatana of the classical authors (*q.v.*). According to a tradition Darius rebuilt the city which had long lain in ruins in order to have a safe asylum for his family and treasures during the war with Alexander. Whether the later citadel of Hamadan actually dated back to such early times must remain uncertain; but it is certain that it was destroyed by Agha Muhammad Khan in 1789 and that the remains, now called Al Musalla, are to be seen outside the town. Another monument of ancient times is the Bab al Asad (Lion gate) which was adorned by a colossal figure of a lion. In A.D. 931 the Bab was destroyed and the lion thrown down, and to this day the inhabitants esteem a figure of a lion lying outside the town as a talisman against

hunger and cold. As a centre of a well populated district, Hamadan developed at a very early period, and is said to have been four parasangs (16 m.) in length. Jews are attracted to the town not only by the favourable conditions of trade, but also by the alleged tombs of Mordecai and Esther, in an insignificant domed building in the middle of the town, to which Jews from other countries as well make a pilgrimage. Hamadan also boasts the tomb of the celebrated philosopher Avicenna (Abu Ali ibn Sina) who died there in 1037.

HAMADHĀNĪ [ABŪ-L FADL AḤMAD IBN UL-ḤUSAIN UL-HAMADHĀNĪ] (967-1007), Arabian writer, known as Badi' uz-Zamān (the wonder of the age), was born and educated at Hamadhān. After 990 he travelled in Jorjān, Nishapur, Khorasan and Sijistān, and finally settled in Herāt under the protection of the vizir of Mahmūd, the Ghaznevid sultan. He was renowned for a remarkable memory and for fluency of speech, as well as for the purity of his language. He was one of the first to renew the use of rhymed prose both in letters and *maqāmas*. (See ARABIA: *Literature*, section "Belles Lettres.")

His letters were published at Constantinople (1881), and with commentary at Beirut (1890); his *maqāmas* at Constantinople (1881), and with commentary at Beirut (1889). S. de Sacy has edited six of the *maqāmas* with French trans. in *Chrestomathie arabe*, vol. iii. (2nd ed., 1827). See also A. von Kremer's *Culturgeschichte des Orients*, ii. (Vienna, 1877).

HAMANDRYAS (*Papio hymandryas*), a name for the sacred baboon of the ancient Egyptians, inhabiting Arabia and Abyssinia. (See BABOON, PRIMATES.)

HAMANN, JOHANN GEORG (1730-1788), German writer on philosophy and theology, was born at Königsberg, Prussia on Aug. 27, 1730, of poor parents. During his restless life he experienced poverty and profound mental struggles. In 1767 he was made translator in the Königsberg office, and ten years later became a storekeeper in a mercantile house. In 1784 the failure of some commercial speculations reduced his means, and about the same time he was dismissed with a small pension from his situation. The kindness of friends, however, enabled him to spend some time with Jacobi at Pempelfort and with Buchholz at Walbergen where he was seized with illness, and died on June 21, 1788.

Hamann's works resemble his life and character. His hatred of system, incapacity for abstract thinking, and intense personality rendered it impossible for him to do more than utter the disjointed, oracular, obscure dicta which gained for him the name of "Magus of the North." His fundamental thought is the unsatisfactoriness of abstraction. Attacking his friend, Kant, for separating matter and form, and sense and understanding, he contends that reason, apart from tradition, belief and experience, only exhibits the contradictions in life. Belief is the groundwork of knowledge and life should be taken as a whole. Hamann used to refer to Bruno's conception of the identity of contraries as representing his own thought.

BIBLIOGRAPHY.—Hamann's works were published by F. Roth (1821-42), by C. H. Gildemeister (6 vols., 1851-73 including a biography), and by M. Petri, *Hamanns Schriften u. Briefe*, 4 vols. (1872-73). See also J. Poel, *Hamann, der Magus im Norden* (2 vols., 1874); J. Claassen, *Hamanns Leben und Werke* (1885); H. Weber, *Hamann u. Kant* (1904), and *Neue Hamanniana* (1905); R. Unger, *Hamann u. die Aufklärung* 2 vols. (Halle, 1925). A comprehensive essay on Hamann is found in Hegel's *Vermischte Schriften*, ii. (*Werke*, Bd. xvii.). On Hamann's influence on German literature, see J. Minor, *J. G. Hamann in seiner Bedeutung für die Sturm- und Drang-Periode* (1881).

HAMAR or STOREHAMMER (GREAT HAMAR), a town of Norway in Hedemarken amt (county), 78 m. by rail N. of Oslo. Pop. (1927), 6,003. It is pleasantly situated between two bays of Lake Mjøsen, and is the junction of the railways to Trondhjem and to Otta in Gudbrandsdal. The existing town was laid out in 1849, and made a bishop's see in 1864. Near the same site there

stood an older town, which, together with a bishop's see, was founded in 1152 by the Englishman Nicholas Breakspeare (afterwards Pope Adrian IV.); but both town and cathedral were destroyed by the Swedes in 1567, though ruins of the latter still exist. The town is a centre for the richest agricultural district in Norway, and has condensed milk factories. It has also steel and iron industries, including the manufacture of railway engines.

HAMĀSA (HAMĀSAH), the name of a famous Arabian anthology compiled by Ḥabīb ibn Aus at-Tā'ī, surnamed Abū Tammām. (See **ABŪ TAMMĀM**.) The collection is so called from the title of its first book, containing poems descriptive of constancy and valour in battle, patient endurance of calamity, steadfastness in seeking vengeance, manfulness under reproach and temptation, all which qualities make up the attribute called by the Arabs *hamāsah* (briefly paraphrased by at-Tibrizī as *ash-shiddah fi-l-amr*). It consists of ten books or parts, containing in all 884 poems or fragments of poems, and named respectively—(1) *al-Ḥamāsa*, 261 pieces; (2) *al-Marāthī*, "Dirges," 169 pieces; (3) *al-Adab*, "Manners," 54 pieces; (4) *an-Nasīb*, "The Beauty and Love of Women," 139 pieces; (5) *al-Hijā*, "Satires," 80 pieces; (6) *al-Adyāf wa-l-Madīḥ*, "Hospitality and Panegyric," 143 pieces; (7) *aṣ-Ṣifāt*, "Miscellaneous Descriptions," 3 pieces; (8) *as-Sair wa-n-Nu'ās*, "Journeying and Drowsiness," 9 pieces; (9) *al-Mulāḥ*, "Pleasantries," 38 pieces; and (10) *Madhammat-an-nisā*, "Dispraise of Women," 18 pieces. The poems are for the most part fragments selected from longer compositions. They are taken from the works of Arab poets of all periods down to that of Abū Tammām himself (the latest ascertainable date being A.D. 832), but chiefly of the Ante-Islamic time (*Jāhiliyyūn*), of the early days of Al-Islām (*Mukhadḍimūn*), and of the reigns of the Omayyad caliphs, A.D. 660-749 (*Islāmiyyūn*). Perhaps the oldest in the collection are those relating to the war of Basūs, which ended with the peace of Dhu-l-Majāz, about A.D. 534.

Most of the poems belong to the class of extempore or occasional utterances, as distinguished from *qaṣīdas*, or elaborately finished odes. While the latter abound with comparisons and long descriptions, the poems of the *Ḥamāsa* are short, direct and for the most part free from comparisons. Abū Tammām in compiling his collection chose hardly anything from the works of the most famous poets of antiquity. Not a single piece from Imra 'al-Qais (Amru-ul-Qais) occurs in the *Ḥamāsa*, nor are there any from 'Alqama, Zuhair or A'shā; Nābiga is represented only by two pieces of four and three verses respectively; 'Antara by two pieces; Tarafa by one piece; Labīd by one piece; and 'Amr ibn Kulthūm by one piece.

The book entitled *an-Nasīb* is, however, an important exception, and contains verses relating to women and love. In the classical age of Arab poetry it was the established rule that all *qaṣīdas* must begin with the mention of women and their charms (*tashīb*), in order that the hearts of the hearers might be softened. These fragments are therefore generally taken from the opening verses of *qaṣīdas*; where this is not the case, they are chiefly compositions of the early Islamic period.

The compiler was himself a distinguished poet and wandered through the Muslim empire living by his skill in panegyric. About A.H. 220 he betook himself to Khurasan, then ruled by 'Abdallah ibn Ṭāhir, whom he praised and by whom he was rewarded; on his journey home to 'Irāk he passed through Hamadhān, and was there detained as a guest of Abu-l-Wafā, son of Salama. During his residence at Hamadhān, Abū Tammām is said to have compiled or composed five poetical works, of which one was the *Ḥamāsa*. This collection remained as a precious heirloom in the family of Abu-l-Wafā until it fell into the hands of Abu-l-'Awādhil, who carried it to Iṣfahān and made it known to the learned of that city.

The worth of the *Ḥamāsa* as a store-house of ancient legend can hardly be exaggerated. The high level of excellence which is found in its selections caused it to be said that Abū Tammām displayed higher qualities in his choice of extracts than in his own compositions. The class of poetry of which the *Ḥamāsa* is a specimen is remarkable for the evident first-hand experience which the singers possessed of all of which they sang. For his-

torical purposes the value of the collection is not small; but most of all there shines forth from it a complete picture of the strenuous life of passion and battle, which marked the valiant stock who bore Islām abroad over the outworn civilizations of Persia, Egypt and Byzantium.

No fewer than 20 commentaries are enumerated by Ḥājji Khalifa. Of these the earliest was by Abū Riyāsh (otherwise ar-Riyāshī), who died in A.H. 257; excerpts from it are frequently given by at-Tibrizī (Tabrizī). He was followed by the famous grammarian Abu-l-Fath ibn al-Jinnī (d. A.H. 392), and later by Shihāb ad-Dīn Aḥmad al-Marzūqī of Iṣfahān (d. A.H. 421). Upon al-Marzūqī's commentary is chiefly founded that of Abu Zakariyā Yahyā at-Tibrizī (b. A.H. 421, d. 502), which has been published by the late Professor G. W. Freytag of Bonn, together with a Latin translation and notes (1828-1851). This work is a treasure of information regarding the classical age of Arab literature. In 1856 an edition appeared at Calcutta under the names of Maulavi Ghulām Rabbānī and Kabīru-d-dīn Aḥmad, which is a simple reprint of Professor Freytag's text (without at-Tibrizī's commentary), and follows its original even in the misprints (corrected by Freytag at the end of the second volume). Freytag's text, with at-Tibrizī's commentary, has been reprinted at Būlāq (1870). In 1882 an edition of the text, with a marginal commentary by Munshī 'Abdul-Qādir ibn Shaikh Luqmān, was published at Bombay.

The *Ḥamāsa* has been rendered into German verse by Friedrich Rückert (Stuttgart, 1846). A small collection of translations, chiefly in metres imitating those of the original, was published in London by Sir Charles Lyall in 1885.

When the *Ḥamāsa* is spoken of, that of Abū Tammām, as the first and most famous of the name, is meant; but several collections of a similar kind, also called *Ḥamāsa*, exist. The best-known and earliest of these is the *Ḥamāsa* of Buhturī (d. A.H. 284), of which the unique ms. now in the Leyden university library, has been reproduced by photo-lithography (1909); a critical edition has been prepared by Professor Chlikho at Beyreuth. Four other works of the same name, formed on the model of Abū Tammām's compilation, are mentioned by Ḥājji Khalifa. Besides these, a work entitled *Ḥamasat ar-Rāh* ("the *Ḥamāsa* of wine") was composed of Abu-l-'Alā al-Ma'arrī (d. A.H. 429). (C. J. L.; X.)

HAMBLEDEN, WILLIAM FREDERICK DANVERS SMITH, 2ND VISCOUNT (1868-1928), was born on Aug. 12, 1868, son of William Henry Smith (q.v.). He succeeded to the viscountcy in 1913, on the death of his mother who had been raised to the peerage in 1891. He was educated at Eton and New college, Oxford, and the year after his father's death succeeded him as Conservative M.P. for the Strand division (1891), holding his seat until 1910. He had many years earlier entered the newspaper distributing firm founded by his grandfather, and the removal of the firm's premises to the site occupied by King's College hospital was the occasion for Hambleden's gift to the hospital of the site at Denmark Hill. From 1915-1916 he served in Gallipoli and Egypt as lieutenant-colonel of the Royal 1st Devon Yeomanry. Hambleden is remembered chiefly for his work for the voluntary hospitals, King's College hospital of which he was chairman at the time of his death, being only one of many which benefited from his interest and generosity. He died on June 16, 1928.

HAMBURG, a State of Germany, on the lower Elbe, bounded by the Prussian provinces of Schleswig-Holstein and Hanover. The whole territory has an area of 160 sq.m., and consists of the city of Hamburg with its incorporated suburbs and the surrounding district, including several islands in the Elbe, five small enclaves in Holstein, the communes of Moorburg in the Lüneburg district of the Prussian province of Hanover and Cuxhaven-Ritzebüttel at the mouth of the Elbe, the islands of Neuwerk and Scharhorn off the coast, and the bailiwick (*amt*) of Bergedorf, which down to 1867 was held in common by Lübeck and Hamburg. Cuxhaven-Ritzebüttel and Bergedorf are the only towns besides the capital. The Geestlande comprise the suburban districts encircling the city on the north and west; the Marschlande includes various islands in the Elbe and the fertile tract of land lying between the northern and southern arms of the Elbe, and

with its pastures and market gardens supplying Hamburg with large quantities of country produce. In the Bergedorf district lies the Vierlande, or Four Districts, celebrated for its fruit gardens. Ritzbüttel with Cuxhaven, also a watering-place, have mostly a seafaring population. Two rivers, the Alster and the Bille, flow through the city of Hamburg into the Elbe, the mouth of which, at Cuxhaven, is 75 m. below the city.

As a State of the republic, Hamburg is represented in the Reichsrat. Its present constitution came into force in 1921. According to this Hamburg is a republic, the government (*Staatsgewalt*) residing in two chambers, the senate and the house of burgesses. The senate, which exercises the greater part of the executive power, is composed of 16 members over 30 years of age, elected from the house of burgesses, itself composed of 160 members over 25 years of age who have been residents for at least one year. They are elected on a basis of proportional representation. The law administered is that of the civil and penal codes of the German republic, and the court of appeal for all three towns is the common *Oberlandesgericht*, which has its seat in Hamburg. There is also a special court of arbitration in commercial disputes and another for such as arise under accident insurance.

From the Reformation to the French occupation in the beginning of the 19th century, Hamburg was a purely Lutheran State; according to the "Recess" of 1529, re-enacted in 1603, non-Lutherans were subject to legal punishment and expulsion from the country. Exceptions were gradually made in favour of foreign residents; but it was not till 1785 that regular inhabitants were allowed some religious freedom. In 1860 full religious liberty was guaranteed, and the identification of church and State abolished. Since 1887 a church rate has been levied on the Evangelical-Lutheran communities, and since 1904 upon the Roman Catholics also. Civil marriages have been permissible in Hamburg since 1866. In 1925 Protestants formed 85%, Roman Catholics 5%, and Jews nearly 2% of the population.

The jurisdiction of the Free Port was on Jan. 1, 1882, restricted to the city and port by the extension of the Zollverein to the lower Elbe, and in 1888 the whole of the State of Hamburg, with the exception of the so-called "Free Harbour" (which comprises the port proper and some large warehouses, set apart for goods in bond), was taken into the Zollverein.

The population increased from 453,000 in 1880 to 1,134,112 in 1925. The population exclusive of the city of Hamburg was 74,554 in 1925. The crops raised in the country districts are principally vegetables and fruit, potatoes, hay, oats, rye and wheat.

HAMBURG, a seaport of Germany, capital of the free State of Hamburg, on the right bank of the northern arm of the Elbe, 75 m. from its mouth at Cuxhaven and 178 m. N.W. from Berlin by rail, is the largest seaport on the continent of Europe. Pop. (1925) 1,075,024. In 1927 the number of ships entering the port was 14,788 with a tonnage of 17,423,197. The city proper lies on both sides of the little river Alster, which, dammed up a short distance from its mouth, forms a lake, of which the southern portion within the line of the former fortifications bears the name of the Inner Alster (*Binnen Alster*), and the other and larger portion, that of the Outer Alster (*Aussen Alster*). The oldest portion of the city lies to the east of the Alster. To the west lies the new town (Neustadt), incorporated in 1678; beyond this and contiguous to Altona is St. Pauli, incorporated in 1876, and towards the north-east St. Georg, which arose in the 13th century but was not incorporated till 1868.

The old town lies low, and it is traversed by a great number of narrow canals or "fleets" (*Fleeten*) which serve as convenient channels for transport of goods. They are bordered by warehouses, cellars and the lower class of dwelling-houses. As they are subject to the ebb and flow of the Elbe, at certain times they run almost dry. The Binnen and Aussen Alster are separated by the Lombardsbrücke and surrounded by newer buildings. Shallow draught screw steamers provide means of communication between the business centre of the city and the outlying suburbs, and down to Glückstadt, Hamburg and Cuxhaven. The largest of the public squares in Hamburg is the Hopfenmarkt, which contains the church of St. Nicholas (Nikolaikirche) and is the prin-

cipal market for vegetables and fruit. Others of importance are the Gänsemarkt, the Zeughausmarkt and the Grossneumarkt. The St. Petrikirche, Nikolaikirche, St. Katharinenkirche, St. Jakobi-kirche and St. Michaeliskirche give their names to the five old city parishes. The old Nikolaikirche was destroyed in the great fire of 1842, and the new building, designed by Sir George Gilbert Scott in 13th century Gothic, was erected 1845-74. The Michaeliskirche, on the highest point in the city, is remarkable for its bold construction, there being no pillars. The St. Petrikirche, originally consecrated in the 12th century and rebuilt in the 14th, was the oldest church in Hamburg; it was burnt in 1842 and rebuilt in its old form in 1844-49. It has the granite columns from the old cathedral. The St. Katharinenkirche and the St. Jakobikirche are the only surviving mediaeval churches.

The new Rathaus, a German Renaissance building, constructed of sandstone in 1886-97 contains the city archives. Immediately adjoining it and connected with it is the exchange, erected in 1836-41 on the site of the convent of St. Mary Magdalen. Along the line of the former town wall are the criminal law courts (1879-82, enlarged 1893) and the civil law courts (finished in 1901). Facing the botanical gardens a new central post-office, in the Renaissance style, was built in 1887. The picture gallery contains works by modern masters, while the museum for art and industry, with which is connected a trades school, founded in 1878, is one of the most important institutions of the kind in Germany. It also contains public zoological gardens, Hagenbeck's private zoological gardens in the vicinity, schools of music and navigation, and a school of commerce. In 1900 a high school for shipbuilding was founded, and in 1901 an institute for seamen's and tropical diseases, with a laboratory for their physiological study, was opened. In 1919 a university was founded in the city.

Transport, Trade and Shipping.—The through railway traffic of Hamburg is practically confined to that proceeding northwards to Kiel and Jutland. On Hamburg converge the lines from Cologne and Bremen, Hanover and Frankfurt-on-Main, from Berlin, via Nelzen, and from Lübeck. Hamburg grew enormously during the last 30 years of the 19th century. Its commerce is almost entirely of the nature of transit trade, for it is not only the chief distributing centre for the middle of Europe of the products of all other parts of the world, but is also the chief outlet for German raw products and manufactures. It was also the port from which the large majority of continental emigrants embarked before 1914. Its principal imports are coffee (of which it is the greatest continental market), tea, sugar, spices, rice, cereals, sago, saltpetre, dried fruits, herrings, ores, tobacco, hemp, jute, cotton, wool, skins, leather, oils, guano, phosphates and coal. It exports machinery, electrical goods, sugar, dairy produce, iron and steel, chemical manures, paper, vegetable oils and fats, maize, cement, chinaware and glassware.

Manufacturing industries developed greatly after 1888, when Hamburg joined the German customs union, and the barriers which prevented goods manufactured at Hamburg from entering into other parts of Germany were removed. The import trade of various cereals by sea to Hamburg is very large, and a considerable portion of this corn is ground at Hamburg itself. There are also, in this connection, numerous bakeries for biscuit, rice-peeling mills and spice mills. Besides the foregoing there are cocoa, chocolate, confectionery and baking-powder factories, coffee-roasting and ham-curing and smoking establishments, lard refineries, margarine, and fish-curing, preserving and packing factories. There are numerous breweries, spirit distilleries and factories of artificial waters. There are large jute-spinning mills and factories for cotton-wool and cotton driving-belts. Among other important articles of industry are tobacco and cigars, hydraulic machinery, electro-technical machinery, chemical products (including artificial manures), oils, soaps, india-rubber, explosives, ivory and celluloid articles, furniture, wall paper and the manufacture of leather.

Shipbuilding is an important industry, and in Hamburg ocean-going steamers of the largest class are built. Along with this we have the allied industries of iron founding, and the manu-

facture of steel plate, ships' paint, oil fuel, cork, nautical and other instruments. Bicycles, sewing machines, carriages and motor cars are also made, and tin, zinc and copper works are found here. In 1888 a portion of the port was set apart as a free harbour, altogether an area of 750 ac. of water and 1,750 ac. of dry land, with a system of docks, basins and quays, and since 1910 the area of the free port has been much enlarged. During the last 25 years of the 19th century the channel of the Elbe was greatly improved and deepened, and during the last two years of the 19th century some £360,000 was spent by Hamburg alone in regulating and correcting this lower course of the river. The total water area of the port is now 4,095 ac., the area for sea-going ships being 2,184 ac., with a quay length of 20 miles.

University.—The University of Hamburg was formed in 1919 from the material of the Colonial Institute, and consists of the faculties of law, medicine, philosophy and natural science. Special facilities exist for study of phonetics and of the history and culture of the Orient generally, of India, China, Japan, Africa and the South seas. Anthropology, folklore and missionary problems are among the many notable features of the courses.

HISTORY

Hamburg probably had its origin in a fortress erected in 808 by Charlemagne, on an elevation between the Elbe and Alster, as a defence against the Slavs, and called Hammaburg because of the surrounding forest (*Hamme*). In 811 Charlemagne founded a church here, perhaps on the site of a Saxon place of sacrifice, and this became a great centre for the evangelization of the north of Europe, missionaries from Hamburg introducing Christianity into Jutland and the Danish island and even into Sweden and Norway. In 834 Hamburg became an archbishopric, St. Ansgar, a monk of Corbie and known as the apostle of the North, being the first metropolitan. In 845 church, monastery and town were burnt down by the Norsemen, and two years later the see of Hamburg was united with that of Bremen and its seat transferred to the latter city. The town, rebuilt after this disaster, was again more than once devastated by invading Danes and Slavs. In 1110 Hamburg, with Holstein, passed into the hands of Adolph I., count of Schauenburg, and it is with the building of the Neustadt (the present parish of St. Nicholas) by his grandson, Adolph III. of Holstein, that the history of the commercial city actually begins. In return for a contribution to the costs of a crusade, he obtained from the emperor Frederick I. in 1189 a charter granting Hamburg considerable franchises, including exemption from tolls, a separate court and jurisdiction, and the rights of fishery on the Elbe from the city to the sea. The city council (*Rath*), first mentioned in 1190, had jurisdiction over both the episcopal and the new town. Craft guilds were already in existence, but these had no share in the government. The defensive alliance of the city with Lübeck in 1241, extended for other purpose by the treaty of 1255, practically laid the foundations of the Hanseatic League (*q.v.*), of which Hamburg continued to be one of the principal members. The internal organization of the city, too, was rendered more stable by the new constitution of 1270, and the recognition in 1292 of the complete internal autonomy of the city by the count of Schauenburg. The exclusion of the handicraftsmen from the *Rath* led, early in the 15th century, to a rising of the craft guilds against the patrician merchants, and in 1410 they forced the latter to recognize the authority of a committee of 48 burghers, which concluded with the senate the so-called First Recess; there were, however, fresh outbursts in 1458 and 1483, which were settled by further compromises. In 1510 Hamburg was made a free imperial city by the emperor Maximilian I.

In 1529 the Reformation was definitively established in Hamburg by the Great Recess of Feb. 19, which at the same time vested the government of the city in the *Rath*, together with the three colleges of the *Oberalten*, the Forty-eight (increased to 60 in 1685) and the Hundred and Forty-four (increased to 180). The ordinary burghesses consisted of the freeholders and the master-workmen of the guilds.

The 17th and 18th Centuries.—The 17th century saw notable developments. Hamburg had established, so early as the 16th

century, a regular postal service with certain cities in the interior of Germany, *e.g.*, Leipzig and Breslau; in 1615 it was included in the postal system of Turn and Taxis. In 1603 Hamburg received a code of laws regulating exchange, and in 1619 the bank was established. In 1615 the Neustadt was included within the city walls. During the Thirty Years' War the city received no direct harm; but the ruin of Germany reacted upon its prosperity, and the misery of the lower orders led to an agitation against the *Rath*, culminating in 1708 in the victory of the democratic factions. The imperial government, however, intervened, and in 1712 the "Great Recess" established durable good relations between the *Rath* and the commonalty.

The trade of Hamburg received its first great impulse in 1783, when the United States, by the Treaty of Paris, became an independent power. From this time dates its first direct maritime communication with America. Its commerce was further extended and developed by the French occupation of Holland in 1795, when the Dutch trade was largely directed to its port. The French Revolution and the later occupation of the city by Napoleon, however, exercised a depressing and retarding effect. Under the long peace which followed the close of the Napoleonic wars, its trade gradually revived, fostered by the introduction of steam navigation and the Declaration of Independence of South and Central America, with both of which it opened close commercial relations. In 1866 Hamburg joined the North German Confederation, and in 1871 became a constituent state of the German empire.

Effects of the World War.—Hamburg's commercial prosperity was seriously affected by the World War. In Nov. 1918, in the troubled times after the Armistice, the Council of Workmen and Soldiers assumed complete political power in the city, and endeavoured to form a state of Great Hamburg; but in the following February, after a conflict with the soldiers of the German *Reich*, the movement was suppressed. (*See H. Ströbel, The German Revolution and After*; Eng. trans., 1923). In Oct. 1923, serious Communist riots again broke out. Barricades were erected in the streets and severe fighting took place. The rising was not put down until a cruiser and three torpedo-boats had entered the harbour and marines had been landed to assist the police. The new Constitution of Hamburg, which was adopted in Dec. 1920, reduced the senate to a democratic and parliamentary Government, the senators being no longer appointed for life but elected on parliamentary lines by the *Bürgerschaft* (representative assembly), which consists of 160 members elected on the system of proportional representation. The franchise is extended to all citizens of the *Reich* who are present in Hamburg on the day of election.

HAMBURG AMERIKA LINE, THE. In 1918 the German mercantile marine was reduced to about 2,000,000 gross tons lying in home ports and about 800,000 gross tons laid up in neutral ports, whereas it had aggregated about 5,200,000 gross tons before the war. At the close of 1923 the Hapag fleet, exclusive of auxiliary vessels, consisted of 75 ocean-going ships aggregating 366,104 gross tons, or just under one-third of its pre-war tonnage. In the early part of 1926, when the Hapag took over the Harman shipping interests, three large vessels totalling 46,000 gross tons passed over to it. The merger of the Austral-Kosmos Lines with Hapag (1926) and by the simultaneous purchase of the shares of the Hugo Stinnes Lines, resulted in additions of 37 Austral-Kosmos vessels totalling 210,000 gross tons and 23 Hugo Stinnes vessels totalling 140,000 gross tons. At the present time the Hapag owns 167 sea-going vessels (not counting 17 ships now building) and about 250 tugs, lighters, steamers employed in the seaside service, and other auxiliary craft, or more than 1,000,000 gross tons altogether.

The first engagements entered into with foreign concerns were the agreements with the American Kerr Steamship Line in respect of the North Atlantic business and with the British firms

THE OLD CITY AND HARBOUR OF HAMBURG

1. A street in Old Hamburg (the *Altstadt*), situated in the lower part of the city, to the east of the river Alster. This district has preserved little of its antiquity, the greater part of it having been destroyed by fire in 1842 and rebuilt on modern lines
2. Barges on a canal in the *Altstadt*. The old town, on low-lying ground, is traversed by a great number of narrow canals or "fleets" bordered by warehouses and serving as convenient channels for the transport of goods
3. View of the harbour of Hamburg, which with its suburbs stretches for 6 miles along the left bank of the Elbe. In the centre foreground is the Niederhafen basin; beyond it, the Grasbrook basin, which is used by French, Swedish and transatlantic vessels; and to the right of this the Sandtor basin, used chiefly by British and Dutch steamers
4. View of the *Fischmarkt* during the early morning market. It is situated in the *Altstadt* just below the University library and is one of the most important squares in the city

of Messrs. Alfred Holt and Co. and Messrs. Ellerman, Bucknall and Co. in respect of the Far Eastern business. In 1920 the Kerr agreement was replaced by one concluded with the Harriman group. The Hapag services to the Far East and the Hugo Stinnes services to the Straits and the Far East were both enlarged. The transaction necessitated the increase in the Company's capital by R.M. 55,000,000 which, after a further increase, stood (1928) at the figure of R.M. 160,000,000.

The losses sustained by the Hapag, as one of the results of the World War, reached the total of 176 sea-going vessels, representing a gross tonnage of 1,235,357 tons. (W. Cu.)

HAMDĀNĪ [ABŪ MOHAMMED UL-ḤASAN IBN AHMAD IBN YA'QŪB UL-HAMDĀNĪ] (d. 945), Arabian geographer, belonged to a family of Yemen. He was held in repute as a grammarian and poet. He compiled astronomical tables, devoted himself to the ancient history and geography of Arabia, and died in prison at San'a in 945.

His *Geography of the Arabian Peninsula* (*Kūāb Jazīrat ul-'Arab*) by far the most important work on the subject, was edited by D. H. Müller (Leiden, 1884). His other important work is the *Ikh̄l* (Crown) concerning the genealogies of the Himyarites and the wars of their kings in ten volumes. Of this, part 8, on the citadels and castles of south Arabia, has been edited by D. H. Müller in *Die Burgen und Schlösser Südarabiens* (Vienna, 1879-81). See G. Flügel, *Die grammatischen Schulen der Araber* (Leipzig, 1862); A. Sprenger, *Alte Geographie Arabiens* (Bern, 1875).

HAMDI BEY, OSMAN (1842-1910), Turkish statesman and art expert, son of Hilmi Pasha, one of the last of the grand viziers of the old régime, was born at Constantinople. The family was of Greek origin. Hilmi Pasha himself, as a boy of 12, was rescued from the massacre of the Greeks at Chios in 1825, bought by Mahmud Pasha, who had him educated in Paris and put him on the road to fortune. Hamdi Bey secured for Turkey the famous Greek sarcophagi found in a seven-chambered tomb in Sidon by the American Dr. Eddy, in 1887, which are among the treasures in the museum of antiquities at Constantinople. These are not only magnificent examples of Greek art of the fifth and fourth centuries B.C., but are in perfect preservation, and the magnificent "Alexander" sarcophagus even retains traces of its original colouring. Hamdi Bey's great service to his country was the assertion of the right of Constantinople to receive the finds made by various archaeological enterprises in the Turkish Empire, in spite of the opposition of the Powers. The museum of antiquities at Constantinople was founded by Hamdi Bey, who was its director from 1882 onwards; it owes much to his enlightened taste and to his energy. Hamdi Bey was an artist of some merit, and founded a modern school of art in Constantinople. He died on Feb. 23, 1910.

His brother, **HALİL EDHEM BEY** (b. 1860), was also a distinguished archaeologist. He held various ministerial posts, and eventually became general director of the Turkish museums in Constantinople.

For the sarcophagi with the discovery of which Hamdi Bey's name is associated see Hamdi Bey and Th. Reinach, *La Nécropole royale de Sidon* (1892-96).

HAMEG, the Arabic name of peoples of Dar Fung province, but little, if at all, Islamized and speaking non-Arabic languages. The province of Dar Fung, representing the southern part of the old kingdom of Sennar and having Abyssinia as its eastern neighbour, is inhabited by Arabs in its northern portion, its southern area (including the hills between the Blue and White Niles from about the latitude of 12° southwards) being anthropologically almost unknown. Here are found a number of peoples who, generally called *Hameg* by the Arabs, commonly speak of themselves by the names of their respective hills. The province is an area of linguistic confusion, and just as the country may be regarded as an eastern extension of Dar Nuba so may its peoples be considered to be aboriginal hillmen, differing in few essentials from the Nuba (*q.v.*) though separated from them by the Nile. In this district Bruce first recorded the ceremonial killing of the local king, and customs pointing in this direction have been recorded from other peoples in the same area. Even at Jebel Guli, on about the same parallel as Roseires, the most Arabicized of

all these hills, there is or was until a few years ago a well developed stone cult. These people traced their descent to the great queen Soba (no doubt a memory of such queens as that Candace who ruled in Gezira in the 3rd century B.C. and so appeared to dominate the north) and when a new "king" was installed he stood on a stone called Soba while his feet were ceremonially washed.

HAMELIN, FRANÇOIS ALPHONSE (1796-1864), French admiral, was born at Pont l'Évêque on Sept. 2, 1796, and sailed as a cabin-boy in the frigate "Vénus" for the Indian Ocean in 1806. In 1810 he was a prisoner in England for a short time. Under the Restoration he held commands in Algerian and Pacific waters. In the Crimean War he collaborated with the English admiral Dundas in the bombardment of Sevastopol. He was minister of marine from 1854 to 1860. His administration was notable for the energy shown in adopting and developing the use of armour. The launch of the "Gloire" in 1859 set the example of constructing sea-going ironclads. The first English ironclad, the "Warrior," was designed as an answer to the "Gloire." When Napoleon III. made his first concession to Liberal opposition, Admiral Hamelin was one of the ministers sacrificed. He held no further command, and died on Jan. 10, 1864.

HAMELN, a town in the Prussian province of Hanover, at the confluence of the Weser and Hamel, 33 m. S.W. of Hanover, on the line to Altenbeken. Pop. (1925) 25,633. The older name of Hameln was Hameloa or Hamelowe, and the town owes its origin to an abbey. It existed as a town in the 11th century. Hameln, fell into French hands and in 1806 it was incorporated in the kingdom of Westphalia. In 1814 it again became Hanoverian, but in 1866 fell with that kingdom to Prussia. The chief public buildings are the minster, dedicated to St. Boniface and restored in 1870-5; the town hall; the so-called Rattenfängerhaus (rat-catcher's house) with mural frescoes illustrating the legend (*see below*); and the Hochzeitshaus (wedding house) with beautiful gables. The principal industries are the manufacture of paper, leather, chemicals and tobacco, sugar refining, and ship-building. There is communication with Karlshafen and Minden by steamboats on the Weser. In order to avoid the dangerous part of the river near the town a channel was cut in 1734, and deepened in 1873.

Hameln is famed for its legend. In 1284 it was infested by a plague of rats, when there appeared a piper who offered for money to charm the vermin into the Weser. His conditions were agreed to, but after he had fulfilled his promise the inhabitants, saying he was a sorcerer, broke their bargain, whereupon he reappeared and played a tune which drew all the children. He led them out to the Koppelberg hill, in which a door opened. He entered and the children after him, all but one who was lame. Some trace the origin of the legend to the Children's Crusade of 1211, others to an abduction of children, though not on quite so large a scale.

HAMERLING, ROBERT (1830-1889), Austrian poet, was born at Kirchenberg-am-Walde, Lower Austria, on March 24, 1830, of humble parentage. In the revolutionary year of 1848 he joined the student's legion and in 1849 shared in the defence of Vienna against the imperialist troops of Prince Windischgrätz. From 1855 to 1866 he was master of the gymnasium at Trieste. After his retirement he lived quietly at his villa in Stiftingstal near Graz, where he died on July 13, 1889. Hamerling's most popular poem is *Ahasver in Rom* (1866), of which the emperor Nero is the central figure. Among his other works are *Venus im Exil* (1858); *Der König von Sion* (1869), generally regarded as his masterpiece; *Die sieben Todsünden* (1872); *Blätter im Winde* (1887); *Homunculus* (1888); *Amor und Psyche* (1882). He also wrote a novel, *Aspasia* (1876), and a tragedy, *Danton und Robespierre* (1870).

A popular edition of Hamerling's works in four volumes was published by M. M. Rabenlechner (Hamburg, 1900). For the poet's life, see his autobiographical writings, *Stationen meiner Lebenspilgerschaft* (1889) and *Lehrjahre der Liebe* (1890); also M. M. Rabenlechner, *Hamerling, sein Leben und seine Werke*, i. (Hamburg, 1896); a short biography by the same (Dresden, 1901); R. H. Kleinert, *R. Hamerling, ein Dichter der Schönheit* (Hamburg, 1889); A. Polzer, *Hamerling, sein Wesen und Wirken* (Hamburg, 1890).

HAMERTON, PHILIP GILBERT (1834-1894), English art critic and man of letters, was born at Laneside, Lancashire, on Sept. 10, 1834. He married a Frenchwoman, and spent much time in France, where he developed a keen appreciation of French art and literature. His more important works on art are: *Etching and Etchers* (1866), which became a standard work; *Contemporary French Painters* (1867); *Painting in France after the Decline of Classicism* (1868); and *The Graphic Arts* (1882). He died near Paris on Nov. 4, 1894.

HAMI, an important oasis in Chinese Turkestan (Sinkiang) in lat. 42° 48' N. and long. 93° 28' E. Hami is situated in the north-east of the Tarim basin, on the southern slopes of the eastern spurs of the Thian Shan Mts., and on the western verge of the Gobi desert. It lies at an elevation of 3,150 ft. Its position as a fertile tract at the point of convergence of the two main routes north and south of the Thian Shan connecting China with the West has given it importance since the westward expansion of the Chinese Empire under the Han dynasty in the first century A.D. It is first mentioned in Chinese history under the name of I-Wu-lu. Whenever China was strong enough to assert her claims to the control of central Asia, it was Hami which served as the main rendezvous and supply base for Chinese forces sent to overcome the hostile nomadic tribes in the north. Its commercial importance was equally great since the Pei-shan desert would have been a far more formidable obstacle if Hami had not been available as a place where caravans could re-victual and where animals could be rested. One serious drawback, however, in early times was the constant liability to raids from the nomadic tribes of the good grazing lands on the northern slopes of the eastern Thian Shan. When the Chinese lost their hold on eastern Turkestan, Hami fell into the hands of the Uighurs, who made it their chief town and held it for several centuries. It continued to be an important Buddhist centre long after Islam was dominant in the west of the Tarim Basin. In the early part of the 17th century, however, Hami was ruled by the Mohammedan khan of Kashgar. It was recovered for the Chinese in 1720 during the period of vigorous expansion under the early Manchus, lost for a short time during the great Mohammedan rebellion of 1865 and again recovered in 1873 as part of the successful reconquest of Sinkiang. Hami is now a small town of about 6,000 inhabitants and is still a busy trading centre. Its population consists in part of descendants of the Uighurs and in part of Mohammedan immigrants from Kashgar, Bukhara and Samarkand.

HAMILCAR BARCA or BARCAS, Carthaginian general and statesman, father of Hannibal, was born c. 270 B.C. During the First Punic War in 247, he took over the chief command in Sicily, which at this time was almost entirely in the hands of the Romans, and seizing Mt. Ercte (Monte Pellegrino, near Palermo), carried his raids as far as the coast of south Italy. By the peace of 241 Hamilcar's unbeaten force was allowed to depart from Sicily without any token of submission. On returning to Africa his troops broke out into open mutiny when their rewards were withheld by Hamilcar's opponents among the governing aristocracy. The serious danger into which Carthage was brought was averted by Hamilcar, whom the government reinstated. After crushing the revolt (237), Hamilcar enjoyed a virtual dictatorship. On his own responsibility he led an expedition into Spain to gain a new empire to compensate Carthage for the loss of Sicily and Sardinia. In eight years by force of arms and diplomacy he secured an extensive territory, but his premature death in battle (228) prevented him from completing the conquest.

This Hamilcar has been confused with another general who succeeded to the command of the Carthaginians in the First Punic War, and after successes at Therma and Drepanum was defeated at Ecnomus (256 B.C.). Apart from subsequent unskillful operations against Regulus, nothing is certainly known of him. For others of the name see **CARTHAGE, SICILY**, Smith's *Classical Dictionary*.

See Polybius i.-iii.; Cornelius Nepos, *Vita Hamilcaris*; Appian, *Res Hispanicae*, chs. 4, 5; Diodorus, *Excerpta*, xxiv., xxv.; O. Meltzer, *Geschichte der Karthager* (1877), ii., also **PUNIC WARS**.

HAMILTON, the name of a famous Scottish family. The first authentic ancestor of the Hamiltons is one Walter FitzGilbert, one of the witnesses (Jan. 10, 1295) to a charter by James,

the high steward of Scotland, to the monks of Paisley; in 1296 his name appears in the Homage Roll as Walter FitzGilbert of "Hameldone." He joined the English party, but after Bannockburn went over to Bruce, was knighted and subsequently received the barony of Cadzow. His younger son John was father of Alexander Hamilton who acquired the lands of Innerwick by marriage, and from him descended a certain Thomas Hamilton, who acquired the lands of Priestfield early in the 16th century. Another Thomas, grandson of this last, who had with others of his house followed Queen Mary and with them had been restored to royal favour, became a lord of session as Lord Priestfield. His eldest son, Thomas, was made an ordinary lord of session as early as 1592 and was eventually created earl of Haddington (q.v.). The 5th earl of Haddington by his marriage with Lady Margaret Leslie brought for a time the earldom of Rothes to the Hamiltons to be added to their already numerous titles.

Sir "David FitzWalter FitzGilbert," who carried on the main line of the Hamiltons, was taken prisoner at Neville's Cross (1346); in 1371 and 1373 he was one of the barons in the parliament. His son David succeeded in the representation of the family, Sir John Hamilton of Fingaltoun was ancestor of the Hamiltons of Preston, and Walter is stated to have been progenitor of the Hamiltons of Cambuskeith and Sanquhar in Ayrshire. David Hamilton, the first apparently to describe himself as lord of Cadzow, died before 1392, leaving four or five sons, from whom descended the Hamiltons of Bathgate and of Bardowie, and perhaps also of Udstown, to which last belong the lords Belhaven. Sir John Hamilton of Cadzow, his eldest son, was twice a prisoner in England. John Hamilton's two younger sons are stated to have been founders of the houses of Dalserf and Raploch. His eldest son, James Hamilton of Cadzow, like his father and great-grandfather, visited England as a prisoner, being one of the hostages for the king's ransom. From him the Hamiltons of Silvertonhill and the lords Hamilton of Dalzell claim descent, among the more distinguished members of the former branch being General Sir Ian Hamilton, K.C.B.

James Hamilton was succeeded by his eldest son Sir James Hamilton of Cadzow, an hereditary lord (1445) of parliament. He married (1474) as his second wife, Mary, sister of James III. and widow of Thomas Boyd, earl of Arran. Their son, James, second lord Hamilton, was created (1503) earl of Arran. Of his many illegitimate children Sir James Hamilton of Finnart, beheaded in 1540, was ancestor of the Hamiltons of Gilkerscleugh; and John, archbishop of St. Andrews, hanged by his Protestant enemies, was ancestor of the Hamiltons of Blair, and is said also to have been ancestor of Hamilton of London, baronet. James, second earl of Arran (q.v.) son of the first earl by his second wife Janet Beaton, was chosen governor to the little Queen Mary, being nearest of kin to the throne through his grandmother, though the question of the validity of his mother's marriage was by no means settled. He received (1549) the duchy of Châtelleraut in France. He was succeeded in the title in 1579 by his eldest son James, who became insane, his brother John, afterwards first marquess of Hamilton, administering the estates. From the third son, Claud, created a lord of parliament as Baron Paisley (1587), descends the duke of Abercorn, heir male of the house of Hamilton.

The first marquess of Hamilton had a natural son, Sir John Hamilton of Lettrick, who was legitimated in 1600 and was ancestor of the lords Bargany. His two legitimate sons were James, 3rd marquess and first duke of Hamilton, and William, who succeeded his brother as 2nd duke and was in turn succeeded under the special remainder contained in the patent of dukedom, by his niece Anne, duchess of Hamilton, who was married in 1656 to William Douglas, earl of Selkirk. The history of the descendants of this marriage belongs to the great house of Douglas, the 7th duke of Hamilton becoming the male representative and chief of the house of Douglas, earls of Angus. Claud Hamilton, Baron Paisley, had five sons, of whom three settled in Ireland, Sir Claud being ancestor of the Hamiltons of Beltrim and Sir Frederick, distinguished in early life in the Swedish wars, being ancestor of the viscounts Boyne.

James, eldest son of Lord Paisley, was created in 1603 lord of

Abercorn, and in 1606 earl of Abercorn and lord of Paisley, Hamilton, Mountcastle and Kilpatrick. His eldest son James, 2nd earl of Abercorn, eventually heir male of the house of Hamilton and successor to the dukedom of Châtellerauld, was created in his father's lifetime lord of Strabane in Ireland, but resigned this title in 1633 in favour of his brother Claud, whose grandson, Claud, 5th Lord Strabane, succeeded eventually as 4th earl of Abercorn. The 8th earl of Abercorn, who was summoned to the Irish house of peers in his father's lifetime as Lord Mountcastle, was created a peer of Great Britain in 1786 as Viscount Hamilton of Hamilton in Leicestershire, and renewed the family's connection with Scotland by repurchasing the barony of Duddingston and later the lordship of Paisley. His nephew and successor was created marquess of Abercorn in 1790, and was father of James, 1st duke of Abercorn.

See the article HAMILTON, MARQUESSSES AND DUKES OF, and other articles on the different branches of the family (e.g., ABERCORN, HADDINGTON and BELHAVEN) in Sir J. B. Paul's edition of Sir R. Douglas's *Peerage of Scotland*; and also G. Marshall, *Guide to Heraldry and Genealogy*.

HAMILTON, MARQUESSSES AND DUKES OF. The holders of these titles descended from Sir James Hamilton of Cadzow (see HAMILTON).

JOHN, 1st marquess of Hamilton (c. 1542-1604), third son of James Hamilton, 2nd earl of Arran (q.v.) and duke of Châtellerauld, was given the abbey of Arbroath in 1551. In politics he was largely under the influence of his unscrupulous younger brother Claud, afterwards Baron Paisley (see HAMILTON). At first hostile to Mary, they later became her devoted partisans. Claud met Mary on her escape from Lochleven and escorted her to Hamilton palace. John appears to have been in France in 1568 when the battle of Langside was fought, and it was probably Claud who commanded Mary's vanguard in the battle. With others of the queen's party they were forfeited by the parliament and sought their revenge on the regent Murray. Although the Hamiltons disavowed all connection with Murray's murderer, James Hamilton of Bothwellhaugh, he had been provided with horse and weapons by the abbot of Arbroath, and it was at Hamilton that he sought refuge after the deed. Their uncle, Archbishop Hamilton, was hanged at Stirling in 1571 for alleged complicity in the murder of Darnley, and is said to have admitted that he was a party to the murder of Murray. At the pacification of Perth in 1573 the Hamiltons abandoned Mary's cause. On the uncertain evidence extracted from the assassin by torture, the Hamiltons had been credited with a share in the murder of the regent Lennox in 1571. In 1579 proceedings against them for these two crimes were resumed, and when they escaped to England their lands and titles were seized by their enemies, James Stewart becoming earl of Arran. John Hamilton presently dissociated himself from the policy of his brother Claud, who continued to plot for Spanish intervention on behalf of Mary. With other Scottish exiles he crossed the border in 1585 and marched on Stirling; he was admitted on Nov. 4, and formally reconciled with James VI., with whom he was thenceforward on the friendliest terms. He was created marquess of Hamilton and Lord Evan in 1599, and died on April 6, 1604.

His eldest surviving son JAMES, 2nd marquess of Hamilton (c. 1589-1625), was created baron of Innerdale and earl of Cambridge in the peerage of England in 1619, and these honours descended to his son James, who in 1643 was created duke of Hamilton (q.v.). William, 2nd duke of Hamilton (1616-1651), succeeded to the dukedom on his brother's execution in 1649. He was created earl of Lanark in 1639, and in the next year became secretary of state in Scotland. Arrested at Oxford by the king's orders in 1643 for "concurrence" with Hamilton, he escaped, and was temporarily reconciled with the Presbyterian party. Sent by the Scottish committee of estates to treat with Charles I. at New-castle in 1646, he sought in vain to persuade the king to consent to the establishment of Presbyterianism in England. On Sept. 26, 1647 he signed on behalf of the Scots the treaty with Charles known as the "Engagement" at Carisbrooke Castle, and helped to organize the second Civil War. In 1648 he fled to Holland; he returned to Scotland with Prince Charles in 1650, and joined in

the Scottish invasion of England. He died on Sept. 12, 1651 from wounds received at Worcester. He left no male heirs, and the title devolved on the 1st duke's eldest surviving daughter Anne, duchess of Hamilton in her own right.

Anne married in 1656 William Douglas, earl of Selkirk (1635-1694), who was created duke of Hamilton in 1660 on his wife's petition, receiving also several of the other Hamilton peerages, but for his life only. He resisted Lauderdale's measures in Scotland, and was dismissed from the privy council in 1676. He presided over the convention of Edinburgh which offered the Scottish crown to William and Mary in March 1689. He died at Holyrood on April 18, 1694. His wife survived until 1716.

JAMES DOUGLAS (1658-1712), 4th duke of Hamilton and duke of Brandon (cr. 1711), eldest son of the preceding and of Duchess Anne, succeeded his mother, who resigned the dukedom to him in 1698. On Nov. 15, 1712 he fought the duel with Charles, Lord Mohun, narrated in Thackeray's *Esmond*, in which both the principals were killed.

The title of Lord Hamilton and that of Viscount Hamilton, in the peerage of Great Britain, conferred on the 8th earl of Abercorn in 1786, are borne by the dukes of Abercorn, whose eldest son is usually styled by courtesy marquess of Hamilton, a title which was added to the other family honours when the 2nd marquess of Abercorn was raised to the dukedom in 1868.

See John Anderson, *The House of Hamilton* (1825); *Hamilton Papers*, ed. J. Bain (2 vols., Edinburgh, 1890-92); Gilbert Burnet, *Lives of James and William, dukes of Hamilton* (1677); *The Hamilton Papers relative to 1638-1650*, ed. S. R. Gardiner for the Camden Society (1880); G. E. C[okayne], *Complete Peerage* (1887-98); an article by the Rev. J. Anderson in Sir J. B. Paul's edition of the *Scots Peerage*, vol. iv. (1907).

HAMILTON, ALEXANDER (1757-1804), American statesman, was born a British subject, on the island of Nevis in the West Indies, on Jan. 11, 1757. He came of good family on both sides. His father was James Hamilton, a Scottish merchant of St. Christopher. His mother, Rachael Fawcett (Faucette, of French Huguenot descent), married a Danish proprietor of St. Croix with whom she lived unhappily and whom she soon left, subsequently living with James Hamilton; her husband procured a divorce in 1759 and the court forbade her remarriage. Whatever the fault or the excuse of the parents, the anxiety bestowed upon these facts by the son's biographers seems exaggerated. Business misfortunes having caused his father's bankruptcy, and his mother dying in 1768, young Hamilton was thrown upon the care of maternal relatives in St. Croix, where, in his 12th year, he entered the counting-house of Nicholas Cruger. Shortly afterward Cruger, going abroad, left the boy in charge of the business. The extraordinary specimens we possess of his letters, mercantile and friendly, written at this time, attest an astonishing poise and maturity of mind. His opportunities for regular schooling must have been very scant; but he early formed the habits of wide reading and industrious study that were to persist through his life. An accomplishment later of great service to Hamilton, common enough in the Antilles but very rare in the English continental colonies, was a familiar command of French. In 1772 some friends, impressed by his talents, made it possible for him to complete his education in the colonies of the mainland. He prepared for college at Elizabethtown, N.J., and in 1774 entered King's college (now Columbia university) in New York city. His studies, however, were interrupted by the Revolutionary War. A visit to Boston confirmed him in an opinion that he should cast his fortunes with the colonists. Into their cause he threw himself with ardour. In 1774-75 he wrote two influential anonymous pamphlets (entitled "A Full Vindication of the Measures of the Congress from the Calumnies of their Enemies," and "The Farmer Refuted") which were attributed to John Jay; they show remarkable maturity and controversial ability, and rank high among the political arguments of the time. Concerning them George Ticknor Curtis (*Constitutional History of the United States*, vol. i. p. 274) has said, "There are displayed in these papers a power of reasoning and sarcasm, a knowledge of the principles of government and of the English constitution, and a grasp of the merits of the whole controversy, that would have

done honour to any man at any age." He then organized an artillery company, was awarded its captaincy on examination, won the interest of Nathanael Greene and Washington by the proficiency and bravery he displayed in the campaign of 1776 around New York city, joined Washington's staff in March 1777 with the rank of lieutenant-colonel, and during four years served as his private secretary and confidential aide. The duties with which he was entrusted—including constant correspondence with Congress, and some very important military missions—attest a complete confidence in his abilities and character. But Hamilton was ambitious for military glory—it was an ambition he never lost; he became impatient of detention in what he regarded as a position of unpleasant dependence, and seized a slight reprimand administered by Washington as an excuse for abandoning his staff position (Feb. 1781; see his *Works*, vol. ix., p. 232); the incident, however, involved no break in their good relations. Later he secured, through Washington, a field command and won laurels at Yorktown, where he led the American column that captured the first redoubt of the British works.

Meanwhile, in 1780, he had married Elizabeth, daughter of Gen. Philip Schuyler, and thus became allied with one of the most distinguished families in New York. Also, he had begun the political efforts upon which his fame principally rests. In letters of 1779–80 he correctly diagnosed the ills of the Confederation, and suggested with admirable prescience the necessity of centralization in its governmental powers. After a year's service in Congress in 1782–83, in which he experienced the futility of endeavouring to attain through that decrepit body the ends he sought, he settled down to legal practice in New York. The call for the Annapolis Convention (1786), however, presented an opportunity which he immediately improved. A delegate from New York, he supported Madison in inducing the Convention to exceed its delegated powers and summon the Federal Convention of 1787 at Philadelphia (himself drafting the call); secured a place on the New York delegation thereto; and, after his anti-Federal colleagues withdrew from the Convention, signed the constitution for his State. So long as his colleagues were present his own vote was useless, and he absented himself for some time from the debates after making one remarkable speech (June 18, 1787). In this he held up the British Government as the best model in the world. It is worth while noting that it was the monarchy of George III. that Hamilton defended and admired. Both parties, as Sir Henry Maine pointed out (*Popular Government*, 1886, pp. 212–13), had in mind "monarchy" as practised by George III. It is with this in mind that the quarrel of Hamiltonians and Jeffersonians is to be judged. Hamilton favoured an elective executive of life tenure, holding an absolute veto on national legislation, and with power to appoint the State governors who should hold a similar veto on State legislation; an upper house chosen for life on a property basis; a lower house (this, doubtless, a sop to democrats!) chosen by manhood suffrage; and control by the Federal Government of all militia. Complete extinction of the States he deemed desirable but impracticable. (See *Works*, vol. i., p. 347; and cp. x., pp. 446, 431, 329.)

Hamilton certainly realized that such proposals could serve no purpose except to focus conservative aims. Though fully conscious that monarchy in America was impossible, he wished to obtain the next best solution in an aristocratic, strongly centralized, coercive, but representative union, with devices to give weight to the influence of class and property. Aside from his one elaborate argument, and membership (undoubtedly, with his admirer Madison as chairman, no fruitless membership) of the committee on style that gave final form to the constitution, he played an inconspicuous part in the Convention. "No man's ideas," he wrote when the work was done, "are more remote from the plan than my own are known to be; but is it possible to deliberate between anarchy and convulsion on one side and the chance of good to be expected on the other?" Unable to secure all that he desired he used his talents and utmost endeavours to secure what was attainable.

To this struggle was due the greatest of his writings, and the greatest individual contribution to the adoption of the new Gov-

ernment, *The Federalist*, a series of essays that appeared in the New York journals between Oct. 1787 and April 1788. Its inception and much more than half its contents were Hamilton's; the rest, Madison's and Jay's (see *Amer. Hist. Review*, vol. ii., pp. 443–60, 675–80). It remains a classic commentary, not merely on American constitutional law but on the principles of Government generally. Guizot said of it that "in its application of elementary principles of government to practical administration" it was the greatest work he knew; and Chancellor Kent declared it—quite justly—to be "equally admirable in the depth of its wisdom, the comprehensiveness of its views, the sagacity of its reflections, and the fearlessness, patriotism, candour, simplicity and elegance with which its truths are uttered and recommended." Sheer will and reasoning could hardly be more brilliantly and effectively exhibited than they were by Hamilton in the New York convention of 1788, whose vote he won, against the greatest odds, for ratification.

When the new Government was inaugurated he became secretary of the treasury in Washington's cabinet. Congress immediately referred to him a press of queries and problems, and there came from his pen a succession of papers that have left the strongest imprint on the administrative organization of the national Government—two reports on public credit (1790), upholding an ideal of national honour higher than the prevalent popular principles; a report on manufactures (1791), advocating their encouragement (e.g., by bounties paid from surplus revenues amassed by tariff duties)—a famous report, one of the first notable revolts against the doctrines of Adam Smith, which has served ever since as a storehouse of arguments for American protective policy, and served also as an inspiration for Friedrich List; a report favouring the establishment of a national bank (1790), the argument being based on the doctrine of "implied powers" in the Constitution, and on the application that Congress may do anything that can be made, through the medium of money, to subserve the "general welfare" of the United States—doctrines that, through judicial interpretation, have revolutionized the Constitution; and, finally, a vast mass of detailed work by which order and efficiency were given to the national finances. In 1793 he put to confusion his opponents who had brought about a congressional investigation of his official accounts. The success of his financial measures was immediate and remarkable. They did not, as is often but loosely said, create economic prosperity; but they propped it, in an all-important field, with order and confidence. His ultimate purpose was always the strengthening of the Union; but before particularizing his political theories, and the political import of his financial measures, the remaining events of his life may be traced.

His activity in the cabinet was by no means confined to the finances. He apparently regarded himself as premier, and sometimes overstepped the limits of his office in interfering with other departments. The heterogeneous character of the duties placed upon his department by Congress seemed in fact to reflect the English idea of its primacy. It is often said that Hamilton's counsels were predominant with Washington. In domestic affairs this is, on the whole, true; partly because their views were naturally sympathetic, and partly because Hamilton's advice was naturally accepted in the field of his special competence where Washington really needed guidance—finance. With regard to foreign relations, common sense and better judgment usually supported Jefferson's counsels—but where those qualities were involved Washington needed no counsel. Neutrality and isolation were American policies (to be found in the letters of every public man) before any occasion arose for their official promulgation. There was here no real difference between Hamilton and Jefferson: one sympathized with England, the other with France, but both desired neutrality. On domestic policy their differences were vital and in their conflicts over Hamilton's financial measures they organized, on the basis of varying tenets and ideals which have never ceased to conflict in American politics, the parties of Federalists and Republicans. In Jan. 1795 Hamilton resigned and returned to the practice of law in New York, leaving it for public service only in 1798–1800, when he was the active head, under Washington (who insisted that Hamilton should be second only to him-

self), of the army organized for war against France. But though in private life he remained the continual and chief adviser of Washington, notably in the serious crisis of the Jay Treaty, of which Hamilton approved, Washington's "Farewell Address" can not fairly be said to have been "written" by Hamilton; for Washington had worked upon it for years, and Madison had contributed to it. But though Washington supplied what he called the "body" to Hamilton, the latter apparently largely redressed it; and in particular he added what he described as "such reflections and sentiments as will wear well, progress in approbation with time, and redound to future reputation"—which can hardly be other than the passages which, to-day, give to the address its life.

After Washington's death the Federalist leadership of John Adams, who had the prestige of a varied and great career and greater strength than any other Federalist with the people, was disputed by Hamilton, who controlled practically all the leaders of lesser rank. Hamilton's faults were glaringly displayed in this connection. He sacrificed his influence and his future in political intrigues. Twice, when Adams had been nominated for the presidency he sought to bar him from that office by manipulations of the electoral college; after Adams became president, and so the official head of the party, Hamilton directed the members of the cabinet, and colluded with Federalist senators, in an endeavour to control the president's policy; and finally, on the eve of the crucial election of 1800, he wrote a bitter personal attack on the president (containing much confidential cabinet information) which he only privately circulated, but which was secured and published by the Democrats.

Had he been prosecuted for this under the Sedition Act passed by his Party, as was threatened by a political opponent, it would have been only a just rebuke to him and to his Party. The result of his efforts against Adams was that his agents were dismissed from the Cabinet, that the president turned to southern Federalists, and that he made peace (in 1799) with France; thereby ending such influence as Hamilton enjoyed, and such ambitions as he may have cherished, as head of the army. Similarly, when in Washington's cabinet, he had carried on for five years behind the back of the secretary of State confidential communications with the British minister, which—aside from the ill effects (discernible in the Jay Treaty) of the false ideas that they conveyed of American sentiment—in substance amounted to intrigue. Again, after Aaron Burr outgeneralled Hamilton in the New York campaign of 1799, carrying the State for the Democrats, Hamilton proposed to Gov. John Jay to call together the out-going Federalist legislature in order to choose Federalist presidential electors, a suggestion which Jay simply endorsed: "Proposing a measure for party purposes which it would not become me to adopt" (*Works*, vol. x., p. 371). Indeed, his opposition to Burr for a decade was conducted very largely by indirection, innuendo and whisper, in letters and conversation.

In short, as a political manager Hamilton, though ready in intrigue, was unsuccessful in it. He was a fighter through and through, and his courage was superb; but he was indiscreet in utterance, impolitic in management, opinionated, self-confident and uncompromising in nature and methods. To considerations of what was politic or practical he could not yield, and yet he could not leave politics alone and devote himself to law. With the establishment of democratic power in 1801 he lost all influence upon national affairs. His courage, and his high ideal of public rectitude were displayed in publishing the details of his *amour* with Mrs. Reynolds, that the favours shown to her complacent husband might permit no suspicion of impropriety in his conduct of the Treasury.

To his antipathy against Adams he sacrificed much prestige; to that against Burr, his life. No matter what may be the final judgment on Burr's character and schemes, doubtless Hamilton judged it a patriotic duty to thwart him in his ambitions; defeating his hopes successively of a foreign mission, the presidency, and the governorship of New York. Unfortunately, personal rivalry was also clearly involved, and personal dislike, and his methods of attack certainly, under the customs of that day, gave abundant cause for the duel in which he died. If his unsparing

denunciations were known to Burr they were ignored by him until his last defeat. After that he forced a quarrel on a trivial bit of hearsay (that Hamilton had said he had a "despicable" opinion of Burr); and Hamilton, believing as he explained in a letter he left before going to his death that a compliance with the duelling prejudices of the time was inseparable from the ability to be in the future useful in public affairs, accepted a challenge from him. The duel was fought at the same spot where his eldest son, a boy of 20, had fallen in a duel in 1801. He was mortally wounded, and died on the following day, July 12, 1804. The tragic close of his career appealed for the moment the fierce hatreds of politics, and his death was very generally deplored as a national calamity.

No emphasis, however strong, upon the mere events of Hamilton's life suffices to show his importance in American history. In his earliest pamphlets he started out with the ordinary pre-Revolutionary Whig doctrines of natural rights and liberty; but the first experience of semi-anarchic States'-rights and individualism released by the Revolution ended his fervour for ideas so essentially alien to his mind, and they have no place in his later writings. The loose and barren rule of the Confederation, its feeble inadequacy of conception, infirmity of power, disintegrating particularism, and vicious finance were realized by many; but none other saw so clearly the concrete nationalistic remedies for these concrete ills, or pursued remedial ends so constantly and so ably. An immigrant, Hamilton had no particularistic ties; he was by instinct a "continentalist" or Federalist. Liberty, he remarked in the New York convention in 1788, was too exclusively considered, but there was another thing equally important: "a principle of strength and stability in the organization . . . and of vigour in its operation." He wanted a strong union and energetic Government that should "rest as much as possible on the shoulders of the people and as little as possible on those of the State legislatures"; that should have the support of wealth and class; that should curb the States to such an "entire subordination" as nowise to be hindered by those bodies; that should overbear all local and sectional prejudices and influences, and control the people. At these ends he aimed with extraordinary skill in all his financial measures—though of course he also regarded them as merely justice to creditors. As early as 1776 he urged the direct collection of Federal taxes by Federal agents. From 1779 onward we trace the idea of supporting Government by the interest of the propertied classes; from 1781 onward the idea that a not-excessive public debt would be a blessing in giving cohesiveness to the union: hence his device by which the Federal Government, assuming the war debts of the States, secured greater resources, based itself on a high ideal of nationalism, strengthened its hold on the individual citizen, and gained the support of property. From 1784 onward he seems to have been clear in his desire for judicial review of all legislation. In his report on manufactures his chief avowed motive was to strengthen the union. To the same end he conceived the constitutional doctrines of liberal construction, "implied powers," and the "general welfare," which were later embodied in the decisions of John Marshall. The idea of nationalism pervaded and quickened all his life and works.

The adoption of the constitution was less the end than the beginning of the struggle between its supporters and its opponents. The issue was not merely one of political abstractions; the literature of the Confederation epoch is full of discussions of class rights and economic interests; *The Federalist*, as Beard says, is "the finest study in the economic interpretation of politics which exists in any language." The constitution's "champions as well as its opponents knew that its real character was to be determined by the measures of law and administration to be established under it. . . . It did not go into effect until the economic measures which its adoption implied were put upon the statute books and carried into execution" (*Economic Interpretation of the Constitution*, pp. 10, 153, 189; *Economic Origins of Jeffersonian Democracy*, pp. 3, 85-86). Here was Hamilton's contribution. He believed with Hume that men are moved only by force and by interest, and in *The Federalist* he remarked: "Every institution will grow and flourish in proportion to the quantity and extent of the means concentrated towards its formation and support." This explains all

his financial measures. Madison and Hamilton reasoned alike, but they parted, as the former stated years later, "upon its plainly becoming his (Hamilton's) purpose to *administration* the government into something totally different from that which he and I perfectly knew the convention when it framed that government intended, and from what the people intended in adopting that framework." With one great exception, the dictum of Guizot is hardly an exaggeration, that "there is not in the Constitution of the United States an element of order, of force, of duration, which he did not powerfully contribute to introduce into it and to cause to predominate."

The exception, as history has shown—though Hamilton, of course, would have held it an element merely of disorder and dissolution—was American democracy. It is a commonplace today that colonial experience shaped the Constitution. It was Hamilton's weakness—and misfortune—that he did not share that experience, and lacked feeling for its lessons. It is a weakness everywhere apparent in his calculations, but especially apparent in his total failure to understand the democracy created by two centuries of frontier life. It explains, also, his total lack of understanding of the West. When scores of thousands of settlers were yearly pouring over the Alleghenies, north and south of the Ohio, he was opposed to the wide distribution of public land; and was so fatuous as to encourage the British minister to believe that his country would share with Great Britain the navigation of the Mississippi. Only a few lesser contemporaries were so lacking in judgment of their own time and place. This misunderstanding of American society, and exaltation of administration over the ends of government, condemned him to increasing isolation and impotence; confidence in the integrity, the self-control, and the good judgment of the people, which was the content of Jefferson's political faith, had almost no place in his theories. "Men," said he, "are reasoning rather than reasonable animals"; "opinion is as much influenced by appearances as by realities"; "I have an indifferent opinion of the honesty of the country." It is easy to understand why he received but twice an office at the hands of the people, and none after 1788. The charge that he laboured to introduce monarchy by intrigue was a gross underestimate of his good sense. The idea, he wrote to Washington, was "one of those visionary things none but madmen could undertake, and that no wise man will believe" (1792). We may accept as just, and applicable to his entire career, the statement made by himself in 1803 of his principles in 1787: "(1) That the political powers of the people of this continent would endure nothing but a representative form of government. (2) That, in the actual situation of the country, it was itself right and proper that the representative system should have a full and fair trial. (3) That to such a trial it was essential that the government should be so constructed as to give it all the energy and the stability reconcilable with the principles of that theory."

Throughout life, however, he held to his preference for such a government as he proposed in the convention of 1787; and though its inconsistency with American tendencies was yearly more apparent, he never ceased to avow on all occasions his aristocratic-monarchical partialities. Since Jefferson's assertions, alike as regards Hamilton's talk and the intent and tendency of his political measures, were, to the extent of the underlying basic fact—but discounting Jefferson's somewhat intemperate interpretations—unquestionably true,¹ it cannot be accounted strange that Hamilton's Democratic opponents mistook his theoretic predilections for positive designs. Nor would it be a strained inference

¹Cf. Gouverneur Morris, *Diary and Letters*, vol. ii., pp. 455, 526, 531 and even Lodge's judgments, *Life*, pp. 90-92, 115-116, 122, 130, 140. When he says (p. 140) that "In Hamilton's successful policy there were certainly germs of an aristocratic republic, there were certainly limitations and possibly dangers to pure democracy," this is practically Jefferson's assertion (1792) that "His system flowed from principles adverse to liberty"; but Jefferson went on to add: "and was calculated to undermine and demolish the republic." Jefferson merely had exaggerated fears of a moneyed political engine, and seeing that Hamilton's measures of funding and assumption did make the national debt politically useful to the Federalists in the beginning he concluded that they would seek to fasten the debt on the country forever.

from much that he said, to believe that he hoped and expected that in the "crisis" he foresaw—and in which he evidently hoped to play a military rôle—when democracy should have caused the ruin of the country, a new government might be formed that should approximate to his own ideals. No Jeffersonian obsession regarding "monocrats" is more fantastic than this counter obsession of his great opponent.

After the Democratic victory of 1800, his letters are but rarely relieved in their sombre pessimism by flashes of hope and courage. "Every day," he wrote, "proves to me more and more that this American world was not made for me." His last letter on politics, written two days before his death, illustrates the two sides of his thinking already emphasized: in this letter he warns his New England friends against dismemberment of the Union as "a clear sacrifice of great positive advantages, without any counterbalancing good; administering no relief to our real disease, which is democracy, the poison of which, by a subdivision, will only be more concentrated in each part, and consequently the more virulent." To the end he never appreciated the value of his own labours, never lost his fear of the States, nor gained faith in the future of the country. He laboured still, in mingled hope and apprehension, "to prop the frail and worthless fabric," but for its spiritual content of democracy he had no understanding, and even in its nationalism he had little hope. (*See his Works*, vol. x., pp. 363, 425, 434, 440, 445.) Yet to no other men, except to Washington and Marshall, does American nationalism owe so much.

In the development of the United States the influence of Hamiltonian nationalism and Jeffersonian democracy has been a reactive union; but changed conditions since Hamilton's time, and particularly since the Civil War, have created misconceptions as to Hamilton's position in his own day. Great constructive statesman as he was, he was also in that day essentially a reactionary. He was in sympathy with the dominant forces of public life only while they took, during the war, the predominant impress of an imperfect nationalism. Jeffersonian democracy came into power in 1800 in direct line with colonial development; Hamiltonian Federalism had been a break in that development; and this alone can explain the ouster of the Federalists despite their brilliant success in constructing the Government. Hamilton stigmatized his great opponent as a political fanatic; but actualist as he claimed to be, himself, he could not see, or would not concede, the predominating forces in American life, and would uncompromisingly have minimized the two great political conquests of the colonial period—local self-government and democracy.

Few Americans have received higher tributes from foreign authorities. Talleyrand, personally impressed when in America with Hamilton's brilliant qualities, declared him greater than Fox and Napoleon. Of the judgments rendered by his countrymen, Washington's confidence in his ability and integrity is perhaps the most significant. Chancellor James Kent, and others only less competent, paid remarkable testimony to his legal abilities. Chief-justice Marshall ranked him second to Washington alone. No appraisal is more justly measured than Madison's (1831): "That he possessed intellectual powers of the first order, and the moral qualities of integrity and honour in a captivating degree, has been awarded him by a suffrage now universal. If his theory of government deviated from the republican standard he had the candour to avow it, and the greater merit of co-operating faithfully in maturing and supporting a system which was not his choice."

In person Hamilton was rather short (5 ft. 7 in.) and slender; in carriage, erect, dignified and graceful. Deep-set dark eyes vivified his features, and set off his light hair and very fair and rosy complexion. His head in the famous Trumbull portrait is boldly poised and striking. The charm of his manners and conversation is attested by all who knew him, and in familiar life he was artlessly simple. Friends he won readily, and held in devoted attachment by a frank, ardent, generous, warm-hearted and high-minded character. As Lodge says, "the roll of his followers is enough of itself to establish his position in American history." It is therefore the more notable that reciprocal confidence and respect took the place, between Washington and Hamilton, of personal attachment—at least as regards Hamilton. This may be under-

stood, considering their extremely different temperaments. It is more difficult to understand why Hamilton—although on the score of personal and Federalist indebtedness he left explicit recognition—never really appreciated Washington's great qualities: Jefferson differed equally from him in temperament and vastly more in opinions, yet fully recognized his greatness. A firm will, tireless energy, courage and bold self-confidence were other leading qualities of Hamilton's nature. Amiability and enthusiastic aggressiveness seem to have been equally characteristic. In his mind, clarity and penetration were matched with logical solidity. Its remarkable quality lay in a combination of acute analysis and grasp of detail with great comprehensiveness of thought. So far as his writings show he was almost wholly lacking in humour, and in imagination little less so. In public speaking, however, he often combined a rhetorical effectiveness and emotional intensity that might take the place of imagination, and enabled him, on the coldest theme, to move the feelings of his auditors.

He died insolvent, leaving a widow and seven children, none of whom revealed the brilliance of their father.

BIBLIOGRAPHY.—Hamilton's Works have been edited by H. C. Lodge (New York, 9 vols., 1885–86, and 12 vols., 1904); all references above are to the latter edition. There are various editions of *The Federalist*, notably those of H. B. Dawson (1863), H. C. Lodge (1888), and—the most scholarly—P. L. Ford (1898); cf. *American Historical Review*, vol. ii, pp. 413, 675. Among modern biographies see A. M. Hamilton, *The Intimate Life of Alexander Hamilton* (1910), very valuable for its materials but both biased and naïve in judgments; H. J. Ford, *Alexander Hamilton* (1920), carefully reasoned; James Schouler, *Alexander Hamilton* (1901), a slender but very judicious study; J. T. Morse, *Life of Alexander Hamilton* (1876), and H. C. Lodge, *Alexander Hamilton* (1882), both partisan; and G. Shea's two books, his *Historical Study* (1877) and *Life and Epoch* (1879). W. G. Sumner's *Alexander Hamilton* (1890) is important for its criticism from the point of view of an American free-trader; see also, on Hamilton's finance and economic views, C. F. Dunbar, *Quarterly Journal of Economics*, vol. iii. (1889), p. 32; E. G. Bourne in *ibid.*, vol. x. (1894), p. 328; E. C. Lunt in *Journal of Political Economy*, vol. iii. (1895), p. 289; W. C. Culbertson, *Alexander Hamilton: an Essay* (New Haven, 1911); and the two indispensable books by C. Beard cited in the text. F. S. Oliver's *Alexander Hamilton: An Essay on American Union* (1906), an English 'study, which uses its subject to illustrate the necessity of British imperial federation, has been criticized as being too partisan. See also James Bryce, "Predictions of Hamilton and de Tocqueville," in *Johns Hopkins University Studies*, vol. v. (Baltimore, 1887); and the capital essay of Anson D. Morse in the *Political Science Quarterly*, vol. v. (1890), pp. 1–23. The unfinished *Life of Alexander Hamilton*, by his son, J. C. Hamilton, going only to 1787 (New York, 1834–40), was superseded by the same author's valuable, but partisan and uncritical *History of the Republic . . . as traced in the Writings of Alexander Hamilton* (New York, 1857–64; Boston, 1879). New materials and viewpoints have rendered somewhat antiquated the earlier biographies mentioned. (F. S. P.)

HAMILTON, ALLEN McLANE (1848–1919), American physician, was born in Brooklyn, N.Y., on Oct. 6, 1848. He graduated from the College of Physicians and Surgeons (Columbia university) in 1870, and engaged in practice in New York city as a specialist in diseases of the mind and nervous system. In 1879 for an essay on "Diseases of the Lateral Columns of the Spinal Cord" he won the first prize given by the American Medical Association. Later he took up more specifically the work of an alienist and medico-legal practitioner. He was present in an advisory capacity at over 100 murder trials where insanity was the issue, notably at the trials of the assassins of Presidents Garfield and McKinley and in the Thaw case. He was greatly influential in the reform of court methods in dealing with criminals of this type. He was visiting surgeon to the epileptic and paralytic hospital on Blackwell's island and from 1900 to 1903 professor of mental diseases at Cornell Medical college. He died at Great Barrington, Mass., on Nov. 23, 1919.

Beside many contributions to medical journals he wrote *Clinical Electro-Therapeutics* (1873); *Nervous Diseases* (1878); *Types of Insanity* (1883); *Insanity in its Medico-Legal Bearings* (1894); *An Intimate Life of Alexander Hamilton* (1910); *Recollections of an Alienist* (1916). See sketch by H. A. Kelly in Kelly and Burrage, *Dictionary of American Medical Biographies* (1928).

HAMILTON, ANTHONY (?1645–1720), French author, was born about 1645, probably in Tyrone or Tipperary. His grandfather, Earl of Aberdare, settled in Ireland in the Plantation

of Ulster. The family moved to France in 1651, and returned at the Restoration to a house near Whitehall. Anthony's sister Elizabeth, *La Belle Hamilton*, married the Comte de Gramont (q.v.). Anthony probably went to France in 1667 with his brother George, after the expulsion of the Roman Catholics from the army. In any case, we find him serving in the *régiment d'Hamilton*, getting wounded in the Palatinate in 1674, and at intervals going over to Ireland for recruits. The regiment was not a success after George's death, and Anthony seems to have left France for Ireland in 1678. James II. gave him command of an Irish regiment in 1687. After the siege of Limerick, Anthony joined the court of James at St. Germain, where he shared the general poverty, and died on April 21, 1720.

The *Memoires du Comte de Gramont* were written, theoretically at Gramont's dictation, at the château of the duchesse du Maine at Sceaux, and published, probably much against the author's will, under the rubric of Cologne, but really in Holland, in 1713. They are after the manner of Bussy Rabutin, half-way between English memoirs and the French *roman prétendu historique*. The prose is typically early 18th century, well-bred and conversational. They are generally accurate in substance, though weak in chronology, and are especially valuable for their pictures of the English court. Of Hamilton's other works, *Le Béliet* is a parody on the followers of Perrault; and the *Contes des Fées*, *Fleur d'Épine*, *Zeneyde* and *Les Quatre Facardines* satirize the romantic tales popularized by Galland's *Arabian Nights*. He also wrote some light verse and corresponded with Lady Mary Wortley Montague. His *Oeuvres Diverses* were collected in 1731.

The *Memoires* were translated into English by Boyer in 1714, and there have been over 30 editions since. See Sayou, *Histoire de la littérature française à l'étranger* (1853); Ruth Clark, *The Life of Anthony Hamilton* (1921).

HAMILTON, ELIZABETH (1758–1816), British author, born in Belfast, of Scottish extraction, spent the greater part of her life in Scotland and at Bath. Her most famous works are *Letters on Education* (1801–2); *The Cottagers of Glenburnie* (1808), and the popular song "My ain Fireside." She died at Harrogate on July 23, 1816.

See E. O. Benger, *Memoirs of Mrs. Elizabeth Hamilton* (1818).

HAMILTON, EMMA, LADY (c. 1765–1815), wife of Sir William Hamilton (q.v.), the British envoy at Naples, and famous as the mistress of Nelson, was the daughter of Henry Lyon, a blacksmith of Great Neston, Cheshire, where she was christened on May 12, 1765. When she went to live with Charles Greville in 1781 she called herself Emily Hart. Under the protection of Greville, whose means were narrowed by debt, she was taught to sing, dance and act with professional skill. In 1782 he introduced her to his friend Romney, whose portraits of her may have somewhat idealized her apparently robust and brilliantly coloured beauty, but her vivacity and powers of fascination cannot be doubted. She seems to have been sincerely attached to Greville. In 1784 his uncle, Sir William Hamilton, saw—and admired—her. Two years later she was sent on a visit to him at Naples, as the result of an understanding between Hamilton and Greville—the uncle paying his nephew's debts and the nephew ceding his mistress. Emma at first resented the exchange, but submitted. Her beauty, her artistic capacity, and her high spirits made her a great favourite in Neapolitan society, and Queen Maria Carolina became closely attached to her. She became famous for her "attitudes," a series of *poses plastiques* in which she represented classical and other figures. On Sept. 6, 1791, during a visit to England, Hamilton married her, in order to justify her public reception at the court of Naples, where she was the channel of communication between the queen and the British minister—sometimes in opposition to the policy of the king. It was claimed that she secured valuable information in 1796, and was of essential service to the British fleet in 1798 during the Nile campaign, by enabling it to obtain stores and water in Sicily. When Nelson returned from the Nile in Sept. 1798 Lady Hamilton subjugated him, and drew him into a most unhappy participation in the domestic troubles of Naples, and when Sir W. Hamilton was recalled in 1800 she travelled with him and Nelson across Europe. In England Lady

Hamilton paraded her hold over Nelson. Their child, Horatia Nelson Thompson, was born on Jan. 30, 1801. On her husband's death in 1803 she received by his will a liferent of £800, and the furniture of his house in Piccadilly. She then lived with Nelson at his house at Merton. On his death she received Merton, and an annuity of £500, as well as the control of the interest of the £4,000 he left to his daughter. But gambling and extravagance kept her poor, and in 1813 she was put in prison for debt and remained there for a year. She died at Calais in distress if not in want on Jan. 15, 1815.

See *The Memoirs of Lady Hamilton* (anon., 1815); and Walter Sichel, *Emma, Lady Hamilton* (1905); J. Turquan and J. d'Auriac, *Une aventurière de haut vol: Lady Hamilton et la Révolution de Naples 1763-1815* (1913). See also the references s.v. NELSON.

HAMILTON, LORD GEORGE (1845-1927), English statesman, was born on Dec. 17, 1845, son of the first duke of Abercorn (q.v.). He was educated at Harrow school and entered the House of Commons in 1868 as member for Middlesex. After 1885 he sat for the Ealing division until his retirement in 1906. Lord George took a keen interest in education throughout his life. He was vice-president of the committee of council on education from 1878 to 1880, and chairman of the London School Board from 1894 to 1895. He was a well-known economist and statistician, and rendered signal service to social science as chairman of the Poor Law Commission, 1904-1909. But his most famous achievements were in two departments of state, the India Office and the Admiralty. Disraeli made him under-secretary at the India Office in 1874, and he spent four years there. He returned to the office as secretary of state in 1895 and held office until 1903. This important period in Indian affairs covered the viceregalities of Lord Elgin and Lord Curzon. At the outset he laid down a moderate frontier policy which secured the Indian government from much fruitless border warfare. His other and perhaps greatest work was done as first lord of the Admiralty (1885-1886 and 1886-1892). He carried through the Naval Defence Act of 1889, which formed the framework for the development of the navy up to the beginning of the great war. He secured the transfer of the control of naval ordnance from the War Office to the Admiralty, created the naval intelligence department and "discovered" Lord Fisher. His long service with Unionist governments ended in 1903, when he and Ritchie resigned on the fiscal question. His last public service was as chairman of the Mesopotamia commission (1916-1917). He died in London on Sept. 22, 1927.

Lord George married in 1871 Lady Maud Lascelles, daughter of the third Earl Harewood. He wrote *Parliamentary Reminiscences and Reflections* (1917).

HAMILTON, SIR IAN STANDISH MONTEITH (1853-), British soldier, was born at Corfu on Jan. 16, 1853. Educated at Wellington college and in Germany, he joined the army in 1872. He served with the 92nd Highlanders in the Afghan War and the Boer War of 1881, and was severely wounded on Majuba hill, one arm being permanently disabled. He was then for several years intermittently on the staff of Sir F. (Lord) Roberts. He served in the Nile Expedition of 1884-85, in Burma in 1886-87, and on the staff of the Chitral Relief Force in 1895. He commanded a brigade on the North-West Frontier in 1897, and afterwards the School of Musketry, Hythe. In the South African War he commanded a mounted infantry division during the advance from Bloemfontein to Pretoria and into the eastern Transvaal. He returned home early in 1901 to become military secretary at the War Office, but towards the end of the year went back to South Africa nominally as chief of the staff to Lord Kitchener, although in reality he was employed chiefly as the commander-in-chief's deputy to control particular groups of operations from time to time during the closing stages of the struggle.

He was afterwards again military secretary and then quartermaster-general at the War Office, and in 1904 he went out to the Far East to accompany the Japanese armies in the field. His impressions under the title *A Staff Officer's Scrap Book* (2 vol., 1906-07), by reason of the interest of its subject, the charm of the author's style, and the combination of war experience and of

imagination which inspired his judgments and criticisms; at once took rank in Europe as a modern military classic. His literary ability, though a token of unusual imagination and clearness of thought, rather prejudiced him throughout his career in the eyes of old-fashioned soldiers. On his return he had charge of the Southern Command until 1909, and was afterwards adjutant-general at the War Office for a year. He took a prominent part on behalf of the voluntary service system during the campaign in favour of compulsory service led by Lord Roberts, and in the course of this controversy he published a book *Compulsory Service* (1910), which he wrote at the request of Lord Haldane. In 1910 he was appointed commander-in-chief in the Mediterranean and inspector-general of the Overseas Forces.

On the outbreak of the World War in 1914 Hamilton served for some months as commander-in-chief of the Home Defence Army in England. Then in March 1915, he was selected to take charge of the Mediterranean Expeditionary Force (see DARDANELLES CAMPAIGN). The naval effort to force the Dardanelles having failed, he found himself obliged to undertake operations in the Gallipoli peninsula, and although his army was very ill-equipped for the task, he succeeded in landing it in the face of the enemy, but was brought to a standstill. Having, after considerable delay, received substantial reinforcements, he made a great effort in August to improve his position, but partly through the inertia of some of the local commanders, sent out without consulting him, the operations miscarried, and a situation of stalemate arose. The Government consulted him in October as to the expediency and feasibility of withdrawing from the peninsula, and on his pronouncing himself strongly opposed to such a policy he was replaced by Sir C. Monro and returned home. In 1920, after the issue of the *Report of the Dardanelles Commission*, he published his own story of the campaign under the title of *Gallipoli Diary* (2 vol., 1920), and in 1921 *The Soul and Body of an Army*. Hamilton was the recipient of many honours, including the G.C.M.G. (1919) and the D.S.O. (1891).

(B. H. L. H.)

HAMILTON, JAMES HAMILTON, 1ST DUKE OF (1606-1649), Scottish nobleman, son of James, 2nd marquess of Hamilton, and of the Lady Anne Cunningham, daughter of the earl of Glencairn, was born on June 19, 1606. As the descendant and representative of James Hamilton, 1st earl of Arran, whose mother was a daughter of James II. of Scotland, he was the heir to the throne of Scotland after the descendants of James VI. He married in his fourteenth year May Feilding, aged seven, daughter of Lord Feilding, afterwards 1st earl of Denbigh, and was educated at Exeter College, Oxford, where he matriculated on Dec. 14, 1621. He succeeded to his father's titles on the latter's death in 1625. In 1628 he was made master of the horse, gentleman of the bedchamber and a privy councillor. In 1631 Hamilton took over a force of 6,000 men to assist Gustavus Adolphus in Germany. He guarded the fortresses on the Oder while Gustavus fought Tilly at Breitenfeld, and afterwards occupied Magdeburg, but his army was destroyed by disease and starvation, and after the complete failure of the expedition Hamilton returned to England in September 1634. He now became Charles I.'s chief adviser in Scottish affairs. In 1638, after the outbreak of the revolt against the English Prayer Book, he was appointed commissioner for Scotland to appease the discontents. He was easily intimidated by the covenanting leaders and accomplished nothing. Charles offered an assembly and a parliament, and eventually revoked the prayer book. On Nov. 21, Hamilton presided over the first meeting of the assembly in Glasgow cathedral, but dissolved it on the 28th on its declaring the bishops responsible to its authority. The assembly, however, continued to sit notwithstanding, and Hamilton returned to England leaving the enemy triumphant and in possession. War was now decided upon, and Hamilton was chosen to command an expedition to the Forth to menace the rear of the Scots. He failed, and in July 1639 resigned his commissionership.

Hamilton supported Strafford's proposal to call the Short Parliament, but otherwise opposed him as the chief adversary of the Scots. In Feb. 1641 he persuaded Charles to admit some of the

parliamentary leaders to the council. Hamilton was now confronted by a new antagonist in Montrose, who detested both his character and policy and repudiated his supremacy in Scotland. On Aug. 10, 1641, he accompanied Charles on his last visit to Scotland.

As no reconciliation proved possible between Charles and Argyll, Hamilton sided with Argyll at Edinburgh. In consequence he received a challenge from Lord Ker, of which he gave the king information, and obtained from Ker an apology. Montrose wrote to Charles declaring he could prove Hamilton to be a traitor. Shortly afterwards the plot—known as the "Incident"—to seize Argyll, Hamilton and the latter's brother, the earl of Lanark, was discovered, and on Oct. 12 they fled from Edinburgh.

In July 1642 Hamilton, who, in spite of his intrigues, retained Charles's confidence, went to Scotland on a hopeless mission to prevent the intervention of the Scots in the war, and a breach then took place between him and Argyll. When in February 1643 proposals of mediation between Charles and the parliament came from Scotland, Hamilton instigated the "cross petition" which demanded from Charles the surrender of the annuities of tithes in order to embarrass Loudoun, the chief promoter of the project, to whom they had already been granted. This failing, he promoted a scheme for outvoting Argyll in the Scottish parliament by sending to Scotland all the Scottish peers then with the king, while Charles was to guarantee the establishment of Presbyterianism in Scotland only. Montrose was eager to strike and anticipate the plans of the Covenanters. Hamilton, however, gained over the queen for his project, and in September was made a duke, while Montrose was condemned to inaction. Hamilton's scheme completely failed. On refusing to take the Covenant, he and Lanark were obliged to leave Scotland. They arrived at Oxford on Dec. 16. Hamilton's conduct had at last incurred Charles's resentment and he was sent, in Jan. 1644, a prisoner to Pendennis Castle, in 1645 being removed to St. Michael's Mount, where he was liberated by Fairfax's troops on April 23, 1646.

Hamilton showed great activity in the futile negotiations between the Scots and Charles at Newcastle. In 1648 he obtained a temporary influence and authority in the Scottish parliament over Argyll, and led a large force into England in support of the king on July 8. He showed complete incapacity in military command; was kept in check for some time by Lambert; and though outnumbering the enemy by 24,000 to about 9,000 men, allowed his troops to disperse over the country and to be defeated in detail by Cromwell, during the three days Aug. 17–19, at the so-called battle of Preston, being himself taken prisoner on the 25th. He was tried on Feb. 6, 1649, condemned to death on March 6 and executed on the 9th.

For his successors see HAMILTON, MARQUESSES AND DUKES OF. **BIBLIOGRAPHY.**—S. R. Gardiner in the *Dict. of Nat. Biog.*; *History of England and of the Civil War*, by the same author; *Memoirs of the Dukes of Hamilton*, by G. Burnet; *Lauderdale Papers* (Camden Society, 1884–85); *The Hamilton Papers*, ed. S. R. Gardiner (Camden Society, 1880) and *addenda* (Camden Miscellany, vol. ix., 1895); *Thomason Tracts* in the British Museum, 550 (6), 1948 (30) (account of his supposed treachery), and 546 (21) (speech on the scaffold).

HAMILTON, JAMES (1769–1831), English educationist, and author of the Hamiltonian system of teaching languages, was born in 1769. He went in 1814 to America, intending to become a farmer and manufacturer of potash; but, changing his plan before he reached his "location," he started as a teacher in New York. There, and in other cities, he was very successful, using a method of teaching languages which he had learned in Hamburg from a French émigré, General d'Angelis. He returned to England in 1823, and taught in various centres. The two master principles of his method were that the language should be presented to the scholar as a living organism, and that its laws should be learned from observation and not by rules. As textbooks for his pupils Hamilton printed interlinear translations of the Gospel of John, of an *Epitome historiae sacrae*, of Aesop's *Fables*, Eutropius, Aurelius Victor, Phaedrus, etc., and many books were issued as Hamiltonian with which he had nothing personally to do. He died on Oct. 31, 1831.

See Hamilton's own account, *The History, Principles, Practice and Results of the Hamiltonian System* (Manchester, 1829; new ed., 1831); Aiberte, *Über die Hamilton'sche Methode*; C. F. Wurm, *Hamilton und Jacotot* (1831).

HAMILTON, JOHN (c. 1511–1571), Scottish prelate and politician, natural son of James Hamilton, 1st earl of Arran, became a monk and abbot of Paisley. After studying in Paris he returned to Scotland, where, under his half-brother, the regent Arran, he was made keeper of the privy seal (1543), bishop of Dunkeld (1545), archbishop of St. Andrews (1546) and finally became treasurer of the kingdom. He was imprisoned, owing to Protestant hostility, in 1563. After his release he was an active partisan of Mary queen of Scots; he baptized the infant James, afterwards King James VI., and pronounced the divorce of the queen from Bothwell. After the battle of Langside, he took refuge in Dumbarton castle. Here he was seized, and on the charge of complicity in the murders of Lord Darnley and the regent Murray he was tried, and hanged on April 6, 1571. The archbishop had three children by his mistress, Grizzel Sempill.

HAMILTON, PATRICK (1504–1528), Scottish proto-martyr of the Reformation, second son of Sir Patrick Hamilton, and of Catherine Stewart, daughter of Alexander, duke of Albany, second son of James II. of Scotland. In 1517 he was appointed titular abbot of Ferne, Ross-shire. He graduated in Paris in 1520, and then went to Louvain, attracted probably by the fame of Erasmus.

On returning to Scotland he became a member of the University of St. Andrews where he conducted as precentor, a musical mass of his own composition in the cathedral. Early in 1527 the attention of James Beaton, archbishop of St. Andrews, was directed to the heretical preaching of the young priest. Hamilton fled to Germany, first visiting Luther at Wittenberg, and afterwards enrolling as a student in the new university of Marburg. He returned to Scotland, bold in the conviction of the truth of his Protestant principles. He accepted Beaton's invitation to a conference at St. Andrews, and for nearly a month was permitted to preach and dispute. At length he was summoned before a council of bishops and clergy presided over by the archbishop; there were 13 charges, seven of which were based on the doctrines affirmed in his *Loci communes*. The council convicted him, after a sham disputation with Friar Campbell, and handed him over to the secular power. The sentence of burning at the stake was carried out on the same day (Feb. 29, 1528) lest he should be rescued by his friends. His courageous bearing greatly helped to spread the Reformation in Scotland. The "reek of Patrick Hamilton infected all it blew on." He represented in Scotland the Lutheran stage of the Reformation. The *Loci communes*, known as "Patrick's Places," set forth the doctrine of justification by faith and the contrast between the gospel and the law in a series of clear-cut propositions. It was translated into English by John Frith (1528), and is to be found in Fox's *Acts and Monuments*.

See Lorimer, *Patrick Hamilton the first preacher and martyr of the Scottish Reformation* (1857).

HAMILTON, ROBERT (1743–1829), Scottish economist and mathematician, born at Pilrig, Edinburgh, on June 11, 1743, was rector of Perth academy (1769–1779), professor of natural philosophy (1779–1817), and of mathematics (1817–1829), at Aberdeen. Hamilton's most important work is the *Essay on the National Debt* (1813), attacking the sinking fund.

HAMILTON, SIR WILLIAM (1730–1803), British diplomatist and archaeologist, son of Lord Archibald Hamilton, governor of Greenwich hospital and of Jamaica, was born in Scotland on Dec. 13, 1730, and served in the 3rd Regiment of Foot Guards from 1747 to 1758. He left the army after his marriage with Miss Barlow, a Welsh heiress from whom he inherited an estate near Swansea upon her death in 1782. From 1764 to 1800 he was British envoy to the court of Naples, held for 36 years—until his recall in 1800. Hamilton made, or caused to be made a series of observations on the action of volcanoes, at Vesuvius and Etna, and published several treatises on earthquakes and volcanoes between 1776 and 1783. He was a notable collector and many of his treasures went to enrich the British Museum. In

1791 he married Emma Lyon. The outbreak of the French Revolution and the rapid extension of the revolutionary movement in Western Europe soon overwhelmed Naples, a situation which he was incapable of dealing with. See, for the rest of his career, the articles HAMILTON, EMMA and NELSON, HORATIO. He died on April 6, 1803.

See E. Edwards, *Lives of the Founders of the British Museum* (1870).

HAMILTON, SIR WILLIAM, BART. (1788-1856), Scottish metaphysician, was born in Glasgow on Mar. 8, 1788, the son of Dr. William Hamilton, professor of anatomy and botany in Glasgow university. He was educated at Glasgow, Edinburgh and Balliol college, Oxford, taking his B.A. in 1811 and becoming a member of the Scottish bar two years later.

Two visits to Germany in 1817 and 1820 led to his study of German and later on to that of contemporary German philosophy, which was then almost entirely neglected in the British universities. In 1821 he was appointed professor of civil history at Edinburgh, after having failed to secure the chair of moral philosophy, which fell vacant on the death of Thomas Brown.

In 1829 appeared his well-known essay on the "Philosophy of the Unconditioned" (a critique of Cousin's *Cours de philosophie*). In 1836 he was elected to the Edinburgh chair of logic and metaphysics, and from this time dates the influence which, during the next twenty years, he exerted over the thought of the younger generation in Scotland through his extensive knowledge embracing anatomy, physiology, literature and theological lore as well as his own particular subjects. His edition of Reid's works appeared in 1846 with only seven of the intended dissertations. During the next few years he elaborated his scheme of logic, an account of his controversy with Augustus de Morgan being contained in the appendices to his *Lectures on Logic*. In 1852 appeared his *Discussions in Philosophy, Literature and Education*, a reprint, with additions, of his contributions to the *Edinburgh Review*. He died in Edinburgh on May 6, 1856.

Hamilton was not a great originator, but he stimulated a spirit of criticism in his pupils, by insisting on the importance of psychology as opposed to the older metaphysical method, and recognized the importance of Aristotle and his commentators and of German philosophy, especially that of Kant, and so brought English philosophy out of insularity.

In logic, Hamilton is now known chiefly as the inventor of the doctrine of the "quantification of the predicate," i.e. that the judgment "All A is B" should really mean "All A is *all* B," whereas the ordinary universal proposition should be stated "All A is *some* B."

BIBLIOGRAPHY.—His posthumous works are his *Lectures on Metaphysics and Logic*, 4 vols., ed. H. L. Mansel, Oxford, and John Veitch (*Metaphysics*, 1858; *Logic*, 1860); and *Additional Notes to Reid's Works*, from Sir W. Hamilton's MSS., ed. H. L. Mansel (1862). See J. Veitch, *A Memoir of Sir W. Hamilton* (1869); J. S. Mill, *Examination of Hamilton's Philosophy* (1865); Hutcheson Sterling, *Sir W. Hamilton* (1881); M. P. Bolton, *Inquisitio Philosophica* (1868); W. H. Monck, *Sir W. Hamilton* (1881); S. V. Rasmussen, *The Philosophy of Sir W. Hamilton* (1925); and J. McCosh, *Scottish Philosophy* (1875).

HAMILTON, WILLIAM (1704-1754), Scottish poet, author of the famous poem "The Braes of Yarrow," wrote a number of odes, epitaphs, songs, etc., the longest of which is "Contemplation, or the Triumph of Love."

See J. Paterson, *The Poems and Songs of William Hamilton* (1850), which contains a life of Hamilton by the editor.

HAMILTON, WILLIAM GERARD (1729-1796), English statesman, popularly known as "Single Speech Hamilton," was born in London on Jan. 28, 1729, and educated at Winchester and at Oriel College, Oxford. His maiden speech, in the House of Commons, delivered on Nov. 13, 1755, during the debate on the address, which excited Walpole's admiration, was, in fact, not the only one which he made in the House. He was one of the commissioners for trade and plantations (1756), chief secretary to Lord Halifax, the lord-lieutenant of Ireland (1761), chancellor of the exchequer in Ireland (1763) and filled other administrative offices.

HAMILTON, SIR WILLIAM ROWAN (1805-1865), Scottish mathematician, was born in Dublin on Aug. 4, 1805. His great mathematical intelligence was awakened by the reading of Newton's *Arithmetica universalis* when he was 12 years old. He went on to the *Principia*, and when he was 17 attacked Laplace's *Mécanique céleste*. In this he detected an error, which was communicated to John Brinkley, then royal astronomer in Ireland, who at once recognized one of the first mathematical minds of the age. Hamilton had a brilliant career at Trinity college, Dublin, but before it was completed, he was appointed, at the age of 22 to the Andrews chair of astronomy in succession to Brinkley. The rest of his life was spent at the observatory at Dunsink, near Dublin, in the close study of mathematics. He was knighted in 1835. At the time of his death, Sept. 2, 1865, he was working on his *Elements of Quaternions*, on which the last six years of his life had been spent.

His earliest papers were the "Theory of Systems of Rays" (*Trans. Roy. Irish Acad.*, 1828-32); in the last of these, by the aid of mathematics, he predicted conical refraction. These were followed by papers on "The Principle of Varying Action" and in 1834 and 1835 by two memoirs "On a General Method in Dynamics." The latter papers made a great addition to the methods of inquiry in dynamics; they have been of great value in mathematical physics and particularly in the Quantum theory. His *Lectures on Quaternions* were published in 1853 and his great book, *The Elements of Quaternions*, posthumously in 1866. In the preface to the *Lectures* he describes the steps by which he reached his important conclusions, a full description of which is given in the article QUATERNIONS. It has been said of his work on this subject that the methods of analysis elaborated by him "are as great an advance over those of analytical geometry, as the latter were over those of Euclidean geometry."

The discoveries, papers and treatises mentioned might well have formed the whole work of a long and laborious life. But he left an enormous collection of ms. books, full to overflowing with new and original matter, which were handed over to Trinity college, Dublin. His investigations connected with the solution of algebraic equations of the fifth degree form a great contribution to science. His paper on *Fluctuating Functions* and his extremely ingenious invention of the hodograph must also be mentioned. Of his investigations into the solution (especially by numerical approximation) of certain classes of differential equations only a few items were published at intervals in the *Philosophical Magazine*. Hamilton was a neat, precise and fastidious writer, and it was probably for this reason that he published so little compared with the extent of his investigations.

His works have been collected and published by R. P. Graves, *Life of Sir W. R. Hamilton* (1882-89).

HAMILTON, a town of Dundas and Normanby counties, Victoria, Australia, on the Wannon river, 197 m. by rail W. of Melbourne. Pop. (1925) 5,209. It is situated where the western edge of the Great Dividing Range dies down to the plain of western Australia, and is thus an important sheep and agricultural country. Mutton is frozen and exported. Hamilton has a number of educational institutions, including the Hamilton and Western District College, and the Hamilton Academy. There is also a race-course.

HAMILTON, one of the chief cities of Canada, capital of Wentworth county, Ontario. It occupies a highly picturesque situation upon the shore of a spacious land-locked bay at the western end of Lake Ontario. It covers the plain stretching between the water-front and the escarpment (called "The Mountain"), this latter being a continuation of that over which the Falls of Niagara plunge 40 m. to the east. Founded about 1778 by one Robert Land, the growth of Hamilton has been steady and substantial, and, owing to its remarkable industrial development, it has come to be called "the Birmingham of Canada." This development is largely due to the use of electrical energy generated by water-power, in regard to which Hamilton stands first among Canadian cities.

The manufacturing interests of Hamilton are varied, including the largest plough works and implement works in the British em-

pire. In addition Hamilton is the centre of one of the finest fruit-growing districts on the continent, and its open-air market is a remarkable sight. The Canadian National, the Canadian Pacific, and the Toronto, Hamilton and Buffalo railway and two electric radial roads afford Hamilton ample facilities for transport by land, while during the season of navigation a number of steam-boat lines supply daily services to Toronto and other lake ports. Entrance into the broad bay is obtained through a short canal intersecting Burlington Beach, which is crossed by two swing bridges, whereof one—that of the Canadian National railway—is among the largest of its kind in the world. Burlington Beach is lined with cottages occupied by the city residents during the hot summer months. Hamilton is rich in public institutions. The educational equipment comprises a normal college, collegiate institute, model school and more than a score of public schools, for the most part housed in handsome stone and brick buildings. There are four hospitals, and the asylum for the insane is the largest in Canada. There is an excellent public library, and in the same building with it a good art school. Since its incorporation in 1833 the history of Hamilton has shown continuous growth. Its population in 1921 was 114,351. It was estimated (1924) at 120,235. The Anglican bishop of Niagara has his seat here, and also a Roman Catholic bishop.

HAMILTON, municipal and police burgh, Lanarkshire, Scotland. Pop. (1921) 39,420. It is situated about 1 m. from the junction of the Avon with the Clyde, 10½ m. S.E. of Glasgow by road, and has stations on the L.M.S.R. and L.N.E.R. Among the subjects of antiquarian interest are Queenzie Neuk, where Queen Mary rested on her journey to Langside, the old steeple and pillory built in the reign of Charles I., the Mote hill, the old Runic cross, and the carved gateway in the palace park. In the churchyard there is a monument to four covenanters who suffered at Edinburgh, on Dec. 7, 1600, whose heads were buried here. Among the industries are manufactures of cotton, lace and embroidered muslins, and carriage-building, and there are also large market gardens, the district being famed for its apples, and some dairy-farming; but the prosperity of the town depends chiefly upon the coal and ironstone of the surrounding country. Hamilton originated in the 15th century under the protecting influence of the lords of Hamilton, and became a burgh of barony in 1456 and a royal burgh in 1548. The latter rights were afterwards surrendered and it was made the chief burgh of the regality and dukedom of Hamilton in 1668, the third marquess having been created duke in 1643. Hamilton palace, a magnificent building in classical style (1822-29), has recently been dismantled, owing to subsidence of the ground. The Low parks, part of the estate, including the mausoleum resembling in design that of Hadrian at Rome, have been bought by the town of Hamilton. The palace occupied most of the site of the original burgh of Netherthorn. At Barncluith, 1 m. S.E. of the town, may be seen the Dutch gardens laid down in terraces on the steep banks of the Avon, planned in 1583 by John Hamilton, an ancestor of Lord Belhaven. About 2 m. S.E. of Hamilton, within the western High park, on the summit of a precipitous rock 200 ft. in height, the foot of which is washed by the Avon, stand the ruins of Cadzow castle, the subject of a ballad by Sir Walter Scott. The castle had been a royal residence for at least two centuries before Bannockburn (1314), but immediately after the battle Robert Bruce granted it to Sir Walter FitzGilbert Hamilton, the son of the founder of the family, in return for the fealty. Near it is the noble chase with its ancient oaks, the remains of the Caledonian forest.

HAMILTON, a village of Madison county, New York, U.S.A., 29 m. S.W. of Utica; on the New York, Ontario and Western railway. The population in 1925 was 1,668. It is the seat of Colgate university (Baptist), founded in 1819, and renamed in 1890 after the Colgate family, several members of which had made liberal gifts. The region was settled about 1790, and the village was incorporated in 1812.

HAMILTON, a city of south-western Ohio, U.S.A., on the Great Miami river, 25 m. N. of Cincinnati; the county seat of Butler county. It is the centre of a network of fine roads, and is served by the Baltimore and Ohio, the Erie and the Pennsylvania

railways, and by inter-urban electric lines. The population in 1920 was 39,675 (90% native white) and was estimated locally at more than 51,000 in 1928. The city has a land area of 5.9 sq.m., and an assessed valuation in 1925 of \$105,766,830. It is surrounded by a rich farming and stock-raising country. There are beautiful parks and substantial public buildings. The manufacturing industries, with an output in 1925 valued at \$54,874,566, are varied and important. They include two factories which make three-fourths of the world's supply of bank vaults and safes, a branch of the Ford motor works, one of the largest plants in the world making heavy machine tools, and one of the largest mills making coated paper. A stockade fort was built here in 1791 by Gen. Arthur St. Clair (on the spot now occupied by the Soldiers' and Sailors' monument) and in 1794 a town was laid out and named Fairfield. The fort was abandoned in 1796. About the same time the town was renamed, after Alexander Hamilton. It became the county seat in 1803, was incorporated as a village in 1810, as a city in 1857. Hamilton was the early home of William Dean Howells, where he learned to set type in his father's printing-shop, and his recollections of it are embodied in *A Boy's Town*.

HAMILTON (GRAND or ASHUANIP), the chief river of Labrador peninsula, Canada. It rises in the Labrador highlands at an elevation of 1,700 ft., its chief sources being among the many irregularly shaped lakes of central Quebec. The river itself flows into a line of weakness on a very old and worn down ancient shield whose present drainage has not been able to establish itself finally since the Ice Age. After a course of 600 m. the river empties into Melville Lake (90 m. long and 18 wide), an extension of Hamilton inlet, on the Atlantic. About 220 m. from its mouth occur the Grand Falls with a vertical drop of 316 ft. Below the falls are many rapids, and the river sweeps through a deep and narrow canyon. In certain portions of the valley spruce and poplars grow to a moderate size. From the head of Lake Attikonak, one of the southern sources of the Hamilton, a steep and rocky portage of less than a mile leads to Burnt Lake, which is drained into the St. Lawrence by the Romaine river.

HAMIRPUR, a town and district of British India, in the Allahabad division of the United Provinces. The town stands on a tongue of land near the confluence of the Betwa and Jumna, 110 m. N.W. of Allahabad. Pop. (1921) 6,760. It was founded, according to tradition, in the 11th century by Hamir Deo, a Karchuli Rajput expelled from Alwar by the Mohammedans.

The district has an area of 2,292 sq.m., and encloses the small Indian states of Sarila, Jigni and Bihat, besides portions of Charkhari and Garrauli. Hamirpur forms part of the great plain of Bundelkhand, which stretches from the banks of the Jumna to the central Vindhyan plateau and contains the famous artificial lakes of Mahoba. These magnificent reservoirs were constructed by the Chandel rajas before the Mohammedan conquest, for purposes of irrigation and as sheets of ornamental water. Many of them enclose craggy islets or peninsulas, crowned by the ruins of granite temples, exquisitely carved and decorated. From the base of this hill and lake country the general plain of the district spreads northward in an arid and treeless level towards the broken banks of the rivers. Of these the principal are the Betwa and its tributary the Dhasan. The deep black soil of Bundelkhand, known as *mār*, retains the moisture under a dried and rifted surface, and renders the district fertile; but the rainfall is precarious, and droughts are frequent. The staple produce is grain of various sorts, the most important being gram. Cotton is also a valuable crop. Agriculture suffers much from the spread of the *kāns* grass, a noxious weed which overruns the fields and is found to be almost ineradicable wherever it has once obtained a footing. In 1921 the population was 440,245. Exports are chiefly agricultural produce and cotton cloth. Rath is the principal commercial centre.

From the 9th to the 10th century this district was the centre of the Chandel kingdom, with its capital at Mahoba. The rajas adorned the town with many splendid edifices, remains of which still exist, besides constructing the noble lakes already described. At the end of the 12th century Mahoba fell into the hands of the Mohammedans. In 1680 the district was conquered by Chhatar Sal, the hero of the Bundelas, who assigned at his death one-third

of his dominions to his ally the peshwa of the Mahrattas. Until Bundelkhand became British territory in 1803 there was constant warfare between the Bundela princes and the Mahratta chieftains.

HAMITIC LANGUAGES. This important family of African languages is now definitely affiliated with the Semitic languages: they constitute a separate division thereof. A brief summary of the facts upon which this conclusion is based is given in *Les Langues du Monde* (Meillet and Cohen, 1924, p. 84, *sqq.*).

Distribution.—This group is spoken in Northern Africa and is divided into three sub-groups. Berber, Libyan and Cushite. The Berber group comprises Kabile and Guanche, now obsolete. To the Libyan group belong Siwah, Libyan and Coptic. The Cushite group consists firstly of the languages spoken by mixed tribes in the Sudan, Adamawa, Bisharin, together with Somali and Galla. In the second group fall Kuhama and one or two smaller languages spoken in the same area. Masai and Nama belong to this group. Both have been influenced by other languages, Nama, now spoken in the southern extremity of Africa, largely by Hottentot and Bushman speech while Masai contains elements derived from the former population. The influence of Hamitic speech upon Amharic (*q.v.*) has been considerable. Although Hamites form an important element in the populations of Uganda and that area generally, in which as elsewhere they form the dominant group, the Bantu language of the people must be regarded as distinct.

Main Characteristics.—In these inflecting languages nouns usually express number, gender and case by suffixes. Verbs use both prefixes and suffixes to form conjugation, voices, moods and tenses. The verb has intensive, reflective, attributive and causative forms. Some languages are more copious and developed than others. The influence of Arabic is found in tense formation, which normally expresses completion or incompleteness of action rather than time. Attention must be drawn to the different kinds of plurals of the nouns. There is a distributive plural in which each of the objects mentioned is regarded as still individual, a collective plural where they form a unity, and generic plurals used of things which appear in mass, such as grass, water, swarms of insects. In some languages, *e.g.*, Masai, gender distinguishes size and strength rather than sex. The relation of plural forms to singular is conditioned by what Meinhof calls the "law of polarity," according to which fields of perception were originally divided into two groups, persons and things, and there are only two classes of genders, one for persons, the other for things. A person therefore, belongs to one or other of the two classes. Persons in the plural are distinguishable from the person regarded as an individual. The person class may be first regarded as male. What, therefore, is not male, belongs to the other or thing class which, therefore, in time adopted the feminine gender. Therefore nouns, which in the singular belong to one gender utilize in the plural the form of plural appropriate to the other gender.

HAMITIC RACES. The term Hamitic as applied to race is not only extremely vague but has been much abused by anthropological writers. Sergi and Meinhof have both made classifications. Sergi includes the Hamites, racially, as a branch of his Mediterranean Race and distinguishes an eastern branch including the Nubians, Bejas, Abyssinians, Gallas, Somalis, Masais, etc., and a northern branch including the Berbers, Fulani, etc. Meinhof's classification is on broad lines essentially the same but he would include the Hottentots, on very unsatisfactory grounds, mainly linguistic. The southern Abyssinians have certainly absorbed Galla blood but the majority are Semitic or Semito-Negroid. There is still some support for the contention that only

Sergi's eastern branch should be called definitely Hamitic and that the northern should take the name Libyan.

The definition of the term Hamitic as an anthropological description is still a type of brown people with frizzy hair, of lean and sinewy physique, with slender but muscular limbs, a thin, straight or even aquiline nose with delicate nostrils, thin lips and

utter absence of prognathism. There is still much confusion in the use of the term from linguistic and ethnologic viewpoints. See G. Sergi, *Africa Antropologia della stirpe camitica* (1897), and *The Mediterranean Race* (1901); C. Meinhof, *Die Hamitensprachen* (Hamburg Kolonials-Institute).

MASAI WARRIORS, OF BRITISH EAST AFRICA

Masai men live in military kraals for several years during their youth, and then settle down as cattle-breeders

Bevis of Hampton make it conceivable that Hamlet is of British rather than of Scandinavian origin. His name does in fact occur in the Irish *Annals of the Four Masters* (ed. O'Donovan 1851). Late in the 10th century there is evidence of the existence of an Icelandic saga of Amloði or Amleth in a passage from the poet Snaebjorn in the second part of the prose *Edda*: "Tis said that far out, off yonder ness, the Nine Maids of the Island Mill stir amain the host—cruel skerry-quern—they who in ages past ground Hamlet's meal." This passage may be compared with one of Hamlet's sayings quoted by Saxo: "As they passed the sand-hills, and bade him look at the meal, meaning the sand, he replied that it had been ground small by the hoary tempests of the ocean." According to Saxo (Books iii. and iv., chaps. 86–106), Hamlet's history is briefly as follows. In the days of Rorik, king of Denmark, Gervendill was governor of Jutland, and was succeeded by his sons Horvendill and Feng. Horvendill married Gerutha, Rorik's daughter, who bore him a son Amleth. But Feng, out of jealousy, murdered Horvendill, and persuaded Gerutha to become his wife, on the plea that he had avenged her of a husband by whom she had been hated. Amleth, afraid of sharing his father's fate, pretended to be imbecile, but the suspicion of Feng put him to various tests. Among other things they sought to entangle him with a young girl, his foster-sister, but his cunning saved him. When, however, Amleth slew the eaves-dropper hidden, like Polonius, in his mother's room, Feng despatched him to England in company with two attendants, who bore a letter enjoining the king of the country to put him to death. Amleth secretly altered the message on their wooden tables to the effect that the king should put the attendants to death and give Amleth his daughter in marriage. After marrying the princess, Amleth returned to Denmark, taking with him certain hollow sticks filled with gold. He arrived in time for a funeral feast, held to celebrate his supposed death. At the feast he plied the courtiers with wine, and during their drunken sleep fastened down over them the woollen hangings of the hall with pegs he had sharpened during his feigned madness, and then set fire to the palace. Having slain Feng with his own sword, he was proclaimed king. Returning to England for his wife he found that his father-in-law and Feng had been pledged each to avenge the other's death. The English king, unwilling personally to carry out his pledge, sent Amleth as proxy wooer for the hand of a terrible Scottish queen Hermuthruda, who had put all former

HAMLET, the hero of Shakespeare's tragedy, a striking figure in Scandinavian romance. Saxo Grammaticus devotes parts of the third and fourth books of his *Historia Danica*, written at the beginning of the 13th century, to the story of Hamlet, Amleth or Amloði, which is supposed to have been contained in the lost Skjöldunga saga. The close parallels between the tale of Hamlet and the English romances of Havelok, Horn and

woosers to death, but fell in love with Amleth. On his return to England his first wife, whose love proved stronger than her resentment, told him of her father's intended revenge. In the battle which followed Amleth won the day by setting up the dead men of the day before with stakes, and thus terrifying the enemy. He then returned with his two wives to Jutland, where he was slain in a battle against Wiglek, Rorik's successor.

The other Scandinavian versions of the tale are: the *Hrolfs-saga Kraba*; the modern Icelandic *Ambales Saga*, a romantic tale the earliest ms. of which dates from the 17th century; and the folk-tale of Brjám which was put in writing in 1707. Saxo Grammaticus was certainly familiar with the Latin historians, and it is most probable that, recognizing the similarity between the northern Hamlet legend and the classical tale of Lucius Junius Brutus, he deliberately added circumstances from the classical story. Dr. O. L. Jiriczek first pointed out the striking similarities existing between the story of Amleth and that of Kei Chosro in the *Shāhnāma* ("The Book of the Kings") of the Persian poet Firdousi, and R. Zenker (*Boeve Amlethus*, pp. 207-268, Berlin and Leipzig, 1904) even concluded that the northern saga rested on an earlier version of Firdausi's story. Further resemblances exist in the *Ambales Saga* to the tales of Bellerophon, of Heracles and of Servius Tullius. In *The Classical Tradition in Poetry* Prof. Gilbert Murray has drawn an interesting parallel between the story of Hamlet and the story of Orestes. The tale of Hamlet's adventures in Britain forms an episode so distinct that it was at one time referred to a separate hero.

The story of Hamlet was known to the Elizabethans in François de Belleforest's *Histoires tragiques* (1559), and as early as 1587 or 1589 Hamlet had appeared on the English stage, as is shown by Nash's preface to Greene's *Menaphon*: "He will afford you whole Hamlets, I should say, handfulls of tragical speeches." The Shakespearian Hamlet owes, however, little but the outline of his story to Saxo. For a discussion of Shakespeare's play and its immediate sources see SHAKESPEARE.

Jiriczek, "Die Amlethsage auf Island," in *Germanistische Abhandlungen*, vol. xii. (Breslau) and "Hamlet in Iran," in *Zeitschr. des Vereins für Volkskunde*, x. (1900); A. Olrik, *Kilderne til Sakses Oldhistorie* (2 vols., 1892-94).

HAMLEY, SIR EDWARD BRUCE (1824-1893), British general and military writer, youngest son of Vice-Admiral William Hamley, was born on April 27, 1824, at Bodmin, Cornwall, and entered the Royal Artillery in 1843. He served in the Crimean War, and in 1859 became professor of military history at the new Staff College at Sandhurst, from which in 1866 he went to the council of military education, returning in 1870 to the Staff College as commandant. From 1879 to 1881 he was British commissioner successively for the delimitation of the frontiers of Turkey and Bulgaria, Turkey in Asia and Russia, and Turkey and Greece, and was rewarded with the K.C.M.G. He became a lieutenant-general in 1882, when he commanded the 2nd division of the expedition to Egypt under Lord Wolseley, and led his troops in the battle of Tel-el-Kebir. From 1885 until his death on Aug. 12, 1893, he represented Birkenhead in parliament in the Conservative interest.

Hamley's principal work, *The Operations of War* (1867), became a text-book of military instruction (last edition 1923). See his *Life* by Innes Shand (1895).

HAMLIN, HANNIBAL (1809-1891), vice-president of the United States (1861-65), was born at Paris, Me., on Aug. 27, 1809. After studying in Hebron academy, he conducted his father's farm for a time, became schoolmaster, and later managed a weekly newspaper at Paris. He then studied law, was admitted to the bar in 1833, and rapidly acquired a reputation as an able lawyer and a good public speaker. Entering politics as an anti-slavery Democrat, he was a member of the State house of representatives in 1836-40, serving as its presiding officer. He was a representative in Congress from 1843-47, and was a member of the U.S. Senate 1848-56. From the very beginning of his service

in Congress he was prominent as an opponent of the extension of slavery; he was a conspicuous supporter of the Wilmot Proviso, spoke against the Compromise Measures of 1850, and in 1856, chiefly because of his party's endorsement of the passage in 1854 of the Kansas-Nebraska bill, which repealed the Missouri Compromise, he withdrew from the Democrats and joined the newly organized Republican Party. The Republicans of Maine nominated him for governor in the same year, and having carried the election by a large majority he was inaugurated in this office on Jan. 8, 1857. In February, however, he resigned the governorship, and was again a member of the Senate 1857-61. From 1861 to 1865, during the Civil War, he was vice-president of the United States. While in this office he was one of the chief advisers of President Lincoln, and urged both the Emancipation Proclamation and the arming of the negroes. After the war he again served in the Senate (1869-81), was minister to Spain (1881-83), and then retired from public life. He died at Bangor, Me., on July 4, 1891.

See *Life and Times of Hannibal Hamlin* (Cambridge, Mass., 1899), by C. E. Hamlin, his grandson.

HAMM, a town in the Prussian province of Westphalia, on the Lippe, 19 m. by rail N.E. from Dortmund on the main line Cologne-Hanover. Pop. (1925) 49,777. Hamm, which became a town about the end of the 12th century, was fortified in 1226, and became a member of the Hanseatic League. In 1666 it came into the possession of Brandenburg, and in 1763 its fortifications were dismantled. The town possesses very extensive wire factories and machine works, breweries and manufactories of brushes, baskets, leather, starch, varnish and oil. Nearby are some thermal baths, and coal mines.

HAMMĀD AR-RĀWIYĀ (Abūl-Qāsim Hammād ibn Abī Laila Sāpūr [or ibn Maisara]) (A.D. 700), Arabic scholar, was of Dailamite descent, but was born in Kufa. He was reputed to be the most learned man of his time in regard to the "days of the Arabs" (i.e., their chief battles), their stories, poems, genealogies and dialects. He is said to have boasted that he could recite a hundred long *qasīdas* for each letter of the alphabet (i.e., rhyming in each letter) and these chiefly from pre-Islamic times. Hence his name *Hammād ar-Rāwiyā*, "the reciter of verses from memory." He was favoured by Yazīd II. and his successor Hishām, who brought him up from Irak to Damascus. To him is ascribed the collecting of the *Mo'allakāt* (q.v.). No diwan of his is extant, though he composed verse of his own.

Biography in McG. de Slane's trans. of Ibn Khallikān, vol. i. and many stories are told of him in the *Kitāb ul-Aghāni*, vol. v.

HAMMANN, OTTO (1852-), German journalist and Foreign Office official, was born on Jan. 23, 1852, at Blankenhain. He was Director of the Press Section of the German Foreign Office (1894-1916). Hammann was the trusted adviser of Prince Bülow, who always kept an attentive eye upon public opinion as reflected or created in the press. He had personally played a leading part in the defensive campaign of the Imperial Chancellor, Count Caprivi, and the Foreign Secretary, Baron Marshall von Bieberstein, in the early '90s, against the Bismarckian *fronde*. He embodied a considerable portion of the information he had obtained in the three volumes of *Erinnerungen* which he published after the Revolution: *Der neue Kurs* (1918), *Zur Vorgeschichte des Weltkriegs* (1918) and *Um den Kaiser, Erinnerungen aus den Jahren 1906-1909* (1919).

HAMMARSKJÖLD, HJALMAR (1862-), Swedish statesman, was born at Tuna on Feb. 4, 1862. He studied at Uppsala, where in 1891 he was appointed professor of civil law. He became minister of justice in the Van Otter cabinet, holding this post from 1901-02, when he was appointed president of the Göta high court. In 1905 he was minister of education in the Lundeburg cabinet and also a delegate to the conference with Norway at Karlstad at the time of the dissolution of the union. He was Swedish minister in Copenhagen from 1905-07 when he became governor (landshöding) of the province (län) of Uppsala. He had been Swedish delegate at The Hague conferences in regard to private international law in 1900 and 1904, and from 1904 was Swedish member of The Hague international board of

arbitration. In 1907 he was Sweden's leading delegate to the Hague Peace Conference and in 1909 acted as president of the Franco-German board of arbitration in regard to the Casablanca affair. He presided in 1913 over the Franco-Italian arbitration court regarding the seizure of vessels during the Tripoli War. In Feb. 1914 he succeeded Staaff as prime minister, retaining this post during the World War until 1917 (*see* SWEDEN). Hammarskjöld became a member of the Institut de Droit International and a curator of the Académie de Droit International at The Hague. In Dec. 1914 he was appointed by the Council of the League of Nations chairman of the commission relating to the codification of international law.

HAMMER, JULIUS (1810–1862), German poet, was born on June 7, 1810, at Dresden, and died at Pillnitz on Aug. 23, 1862. Hammer's *Schau' um dich, und schau' in dich* (1851), which made his name, has passed through more than 30 editions. It was followed by *Zu allen guten Stunden* (1854), *Fester Grund* (1857), *Auf stillen Wegen* (1859) and *Lerne, liebe, lebe* (1862).

HAMMER, an implement consisting of a shaft or handle with head fixed transversely to it. The head, usually of metal, has one flat face, the other may be shaped to serve various purposes, e.g., with a claw, a pick, etc. The implement is used for breaking, beating, driving nails, rivets, etc., and the word is applied to heavy masses of metal moved by machinery, and used for similar purposes. (*See* TOOL.) The word is also applied to many objects resembling a hammer in shape or function. Thus the "striker" in a clock, or in a bell, when it is sounded by an independent lever and not by the swinging of the "tongue" is called a "hammer"; similarly, in the "action" of a pianoforte the word is used of a wooden shank with felt-covered head attached to a key, the striking of which throws the "hammer" against the strings. In the mechanism of a fire-arm the "hammer" is that part which by its impact on the cap or primer explodes the charge. (*See* GUN.)

The hammer, more usually known by its French name of *martel de fer*, was a mediaeval hand-weapon. With a long shaft it was used by infantry, especially when acting against mounted troops. With a short handle and usually made altogether of metal, it was also used by horse-soldiers.

HAMMERBEAM ROOF, in architecture, an open timber roof in which the trusses have no true cross ties, but are framed

SPECIMENS OF HAMMERS
A, cross pane pin hammer. B, claw hammer. C, ball pane engineer's hammer

HAMMERBEAM ROOF IN WESTMINSTER HALL, A FINE EXAMPLE OF THE ARCHED TYPE SHOWING ITS GREAT STYLE AND DIGNITY

together with a series of horizontal and vertical members bracing the main rafter in triangles, and tied together by curved brackets

and braces. The horizontal beams are known as hammerbeams. In the greater number of cases there is an intermediate tie, about one-third of the way down the rafters, and each truss has one hammerbeam on each side with a post extending from its outer end up to the intersection of rafter and cross tie. The hammerbeam is supported by a bracket from the wall and the posts tied to the cross tie by curved members which sometimes take the form of a complete pointed arch. In the earliest extant example, which is also one of the largest, that over Westminster hall, London (1395–99, 68 ft. span), an additional complete pointed arch member adds strength to the construction. The hammerbeam truss was frequently used over the naves of parish churches during the 15th and 16th centuries, as in Bacton church, Suffolk, and in March and Knappton churches, where the hammerbeams are carved with angels. This type of roof was also used over manor and other halls. The great hall of Hampton Court palace (1534–35) and that of Eltham palace (16th century), and the halls of Charterhouse (17th century) and the Middle Temple, London (1570), where there are two rows of hammerbeams, are good examples.

HAMMERFEST, the most northerly town in Europe. Pop. (1927), 3,470. It is situated on an island (Kvalø) off the north-west coast of Norway, in Finmarken amt (county), in 70° 40' 11" N., the latitude being that of the extreme north of Alaska. In spite of this, its average January temperature is little below freezing point, owing to the influence of the warm westerly winds and N. Atlantic drift, and the harbour is ice-free. The district around is barren and naturally treeless, but a "forest" of birches has been successfully planted. Hammerfest is 674 m. by sea N.E. of Trondhjem, and 78 S.W. from the North Cape. The narrow strait Strømmen separates Kvalø from the larger Seiland, whose snow-covered hills with several glaciers rise above 3,500 ft., while an insular rampart of mountains, Sorø, protects the strait and harbour from the open sea. The town is timber-built and modern; much of it having been rebuilt after fire in 1890. The sun does not set at Hammerfest from May 13 to July 29. This is the busy season of the townsfolk. Vessels set out to the fisheries, as far as Spitsbergen and the Kara Sea; and trade is brisk, not only Norwegian and Danish but British, German and particularly Russian vessels engaging in it.

Cod-liver oil, train oil and salted fish are exported with some reindeer-skins, fox-skins and eiderdown; and coal and salt for curing are imported. In the spring the great herds of tame reindeer are driven out to swim Strømmen and graze in the summer pastures of Seiland; towards winter they are called home again. From Nov. 18 to Jan. 23 the sun is not seen, and the enforced quiet of winter prevails. Electric light was introduced in the town in 1891, and it is the wireless station for Spitsbergen.

HAMMERHEAD SHARK. Any of several species of ovoviviparous sharks of the genus *Sphyrna*, characterised by the unique configuration of the head, the anterior portion of which resembles a hammer. They are formidable and ferocious and occur in all tropical and sub-tropical seas, particularly in the Indian ocean. The common hammerhead shark (*S. zygoena*), which attains a length of 16 ft., occurs on the milder coasts of Europe and ranges northward along American shores to Massachusetts and California. *See* SHARKS, SELACHIANS.

HAMMER-KOP or **HAMMERHEAD** (*Scopus umbretta*), an African bird, put in a family, *Scopidae*, between the shoe-bills and storks. It inhabits nearly the whole of Africa and Madagascar, frequenting wooded districts. Though not larger than a raven, it builds a nest some six feet in diameter, with a flat-topped roof and a small hole for entrance and exit, placed on a tree or a rocky ledge. In this it lays three to five white eggs. The bird, of brown colour, slightly glossed with purple and its tail barred with black, has a long crest, generally borne horizontally, and that has given rise to its common name. It is also called the tufted umbre, or in French *umbrette*, from the almost uniform earthy brown (*umber*) colour of the plumage. The bird stands beside a stream, with head drawn in like a heron, watching for fish or frogs.

HAMMER-PURGSTALL, JOSEPH, FREIHERR VON (1774–1856), Austrian orientalist, was born at Graz on June 9,

1774. Entering the diplomatic service in 1796, he held a series of appointments in the Near East. He retired from the service in 1835, and died at Vienna on Nov. 23, 1856. For 50 years Hammer-Purgstall wrote incessantly on the most diverse subjects and published numerous texts and translations of Arabic, Persian and Turkish authors. He did for Germany the same work that Sir William Jones (*q.v.*) did for England and Silvestre de Sacy for France. He was an assiduous worker, and in spite of many faults did more for oriental studies than most of his critics put together. His principal work is his *Geschichte des osmanischen Reiches* (10 vols., Pesth, 1827-35; French trans. 1835-43). Among his other works are *Gesch. der Assassinen* (1818; Eng. trans. 1835); *Constantinopolis und der Bosporos* (1822); *Sur les origines russes* (St. Petersburg, 1825); *Geschichte der osmanischen Dichtkunst* (1836); *Geschichte der Goldenen Horde in Kiptschak* (1840); *Geschichte der Chane der Krim* (1856); and an unfinished *Literaturgeschichte der Araber* (1850-56).

For a full list of his works, which amount in all to nearly 100 volumes, including his texts and translations, see *Comptes rendus* of the Acad. des Inscr. et des Belles-Lettres (1857). See also Schlottman, *Joseph von Hammer-Purgstall* (Zürich, 1857).

HAMMERSMITH, a western metropolitan borough of London, England, bounded E. by Kensington and S. by Fulham and the river Thames, and extending N. and W. to the boundary of the county of London. Pop. (1921) 130,295. The name appears in the early forms of *Hermodewode* and *Hamersmith*; the derivation is probably from the Anglo-Saxon, signifying the place with a haven (*hythe*). Hammersmith is mentioned with Fulham as a winter camp of Danish invaders in 879, when they occupied the island of Hame, identified with Chiswick Eyot. Hammersmith consists of residential streets. Shepherd's Bush in the east is a populous and poor quarter. Boat-building yards, lead-mills, oil mills, distilleries, coach factories, motor works, and other industrial establishments are found in the borough. Old Hammersmith bridge, designed by Tierney Clark (1824), was the earliest suspension bridge erected near London, and was found insecure and replaced in 1884-87. Until 1834 Hammersmith formed part of Fulham parish. Its church of St. Paul was built as a chapel of ease to Fulham, and consecrated by Laud in 1631. The existing building dates from 1890. St. Paul's school, one of the principal public schools in England, was founded in or about 1509 by John Colet, dean of St. Paul's, under the shadow of the cathedral church. But it appears that Colet actually refounded and re-organized a school which had been attached to the cathedral of St. Paul from very early times; the first mention of such a school dates from the early part of the 12th century. The school was moved to its present site in Hammersmith road in 1883. The number of foundation scholars is 153, according to the number of fishes taken in the miraculous draught. The school governors are appointed by the Mercers' Company (by which body the new site was acquired), and the universities of Oxford, Cambridge and London. There are, besides, the Edward Latymer foundation school for boys (1624), part of the income of which is devoted to general charitable purposes; the Godolphin school, founded in the 16th century and remodelled as a grammar school in 1861, Nazareth House of Little Sisters of the Poor and other institutions. At Shepherd's Bush are the grounds and buildings first occupied by the Franco-British Exhibition of 1908, including a stadium for athletic displays. In the neighbourhood of the Mall, bordering the river, are the house where Thomson wrote his poem "The Seasons," and Kelmscott house, the residence of William Morris. The parliamentary borough of Hammersmith returns two members.

HAMMER THROWING, a feat consisting of hurling to the greatest possible distance an implement of specified weight and design, styled a "hammer," so that it shall fall within a 90° sector marked upon the ground, while the thrower remains within a 7ft. circle from which the throwing takes place. The sport is probably of Celtic origin. Mention is made in the *Book of Leinster* of the *roth cleas*, or wheel feat, at the Tailteann games at Tara in Ireland. It is believed that the earliest missile employed was a chariot wheel attached to a fixed axle and that a large stone was

substituted instead of the wheel at the beginning of the Christian era. Later still, a blacksmith's sledge-hammer was preferred, and the first real hammer throwing became known throughout England, Scotland and Ireland. The sport was encouraged by Edward II. and practised proficiently by Henry VIII.

Quite early in the days of the 19th century hammer throwing competitions became very popular, and men began to cast round for a means of throwing further. The oblong hammer head then gave place to a lead or iron ball, weighing 16 lb. or 21 lb., and next, the stiff wooden shaft was replaced with flexible cane or whalebone about $\frac{3}{4}$ in. in diameter. In those days the thrower stood at a mark, whirled the hammer several times round his head and let it fly away backwards over his shoulder. In this style 110ft. was beaten, but 120ft. never fairly reached.

A very big improvement came about when the Irish school of athletes evolved the notion that much more force must be generated if the hammer head, in describing the circumference of a circle, was attached not to a fixed, but to a revolving central point, *i.e.*, the thrower's body, which would generate its own momentum. This led to the modern method of delivering the throw at the end of one, two or even three turns within the narrow confines of the 7ft. circle. Another improvement which has made the tremendous modern records possible is the evolution of the present-day implement, which is a "hammer" by title of courtesy alone. The head comprises a lead or brass shell attached by a ball-bearing swivel to a straight length of steel spring wire not less than $\frac{3}{4}$ in. in diameter, terminating in either a single or double loop. The total weight of the hammer as thrown is 16 lb. and the length over all not more than 4 feet. Thus the greatest mechanical advantage, that of having the entire weight of the missile at the end, as well as the least friction, has been obtained.

The second turning movement was introduced into hammer throwing by J. J. Flanagan, an Irish-American. Flanagan set the world's record mark at 172ft. 11in. in 1904; but, meantime, he had been beaten by A. D. Plaw, University of California, who was using three turns. Flanagan realized that he had reached his limit with the two turn method and for three years he worked patiently until he was able to control the throw fully with three turns. With this style he still further increased his record to 181 feet. Since Flanagan's time there have been two even greater throwers: F. D. Tootell, Bowdoin college, who holds the All-American collegiate record of 181ft. 6 $\frac{1}{2}$ in., and the Irish-American, P. Ryan, who in 1913 set up the wonderful record of 189ft. 6 $\frac{1}{2}$ inches. Ryan stands 6ft. 2in. in height and, in his prime, weighed just about 17 stone (238 lb.).

One of the most marvellous throwers of all time was the late A. E. Flaxman, who fell in the first battle of the Somme, July 1, 1916. This Yorkshireman stood 5ft. 9in. in height, weighed less than 11 stone (154 lb.), and yet, employing four turns, threw over 150ft., or rather more than one foot of distance for every pound of his own weight.

In Scotland there is still held a championship for throwing the stiff-shafted hammer from the standing position, but this form of throwing is not used elsewhere. The orthodox style of throwing the 16 lb. hammer is a championship event in almost every country nowadays; it is also an Olympic event. The sport is essentially one which should be practised by big men of exceptional strength and quickness; and whose senses of rhythm and timing are fully developed. Some idea may be had of the strength which is necessary for the practice of this sport when it is stated that in the case of a 16 lb. hammer being thrown to a distance of even 150ft., the centrifugal force exerted or, in other words, the pull upon the thrower's arms and body is equal to 366 pounds. It is also interesting to note that the velocity of the hammer at the instant of release from the hands is 69ft. per second; if the throw is made at the correct angle of 45° the greatest vertical height attained during its flight is 37ft. 6in., and the time of its flight is just over 3 seconds.

Method of Throwing.—The athlete takes up his position at the rear edge of the circle with his back turned towards the direction in which the throw is to be made, feet about 18in. apart. The last joints of the fingers only are inserted in the loops of the

handle, the hammer-head rests upon the ground to the right and so far back that the thrower's hands are on a level with his knee. Next, the hammer is raised and swung three or four times about the head. When sufficient momentum has been set up, the athlete pivots sharply on his left foot, places down the right foot and repeats the evolution two, three or even four times, taking care always to keep his body moving well ahead of the hammer. The speed increases with each turn. The throw is made at the end of the final turn by a complete straightening of the body and arms. The delivery is made over the left shoulder, and, immediately afterwards, the thrower reverses his position, so that he ends up facing the direction of the flight of the hammer. The longest throw made with a wooden-shafted hammer was that of T. R. Nicholson, Scotland, 1927, 146ft., when he was nearly 48 years of age.

See F. A. M. Webster, *Athletics* (1925); Siliverstrand and Rasmussen, *Text Book of Athletics* (1926); T. E. Jones, *Track and Field* (1926). (F. A. M. W.)

HAMMER-TOE, a painful condition in which a toe is rigidly bent and the salient angle on its upper aspect is constantly irritated by the boot and develops a corn (*q.v.*). It is treated surgically, not as formerly by amputation of the toe, but the toe is made permanently to lie flat by the simple excision of the small digital joint. Even in extremely bad cases of hammer-toe the operation of resection of the head of the metatarsal phalanx is to be recommended rather than amputation.

HAMMOCK, a hanging bed or couch, perhaps derived from the hamack tree, the bark of which was used by the natives of Brazil to form the nets, suspended from trees, in which they slept.

HAMMOND, HENRY (1605-1660), English divine, was born at Chertsey in Surrey on Aug. 13, 1605. He was educated at Eton and at Magdalen college, Oxford, and took orders in 1629. The earl of Leicester presented him to the living of Penshurst in Kent in 1633. In 1643 he was made archdeacon of Chichester. He was a member of the convocation of 1640, and was nominated one of the Westminster Assembly of divines. Instead of sitting at Westminster he took part in the unsuccessful rising at Tunbridge in favour of King Charles I., and was obliged to flee in disguise to Oxford, then the royal headquarters. He accompanied the king's commissioners to London, and afterwards to the Uxbridge convention in 1645, where he disputed with Richard Vines, one of the parliamentary envoys. He attended the king as chaplain during his captivity. When Charles was deprived of all his loyal attendants at Christmas 1647, Hammond returned to Oxford and was made subdean of Christ Church, but was removed from all his offices by the parliamentary visitors, who imprisoned him for ten weeks. Afterwards he was permitted to retire to the house of Philip Warwick at Clapham, Bedfordshire. In 1650, having regained his full liberty, Hammond betook himself to the friendly mansion of Sir John Pakington, at Westwood, in Worcestershire, where he died on the 25th of April 1660, on the eve of his preferment to the see of Worcester.

His Works (4 vols., 1674-84) contain an admirable biography of him by Bishop Fell, reprinted in C. Wordsworth, *Ecclesiastical Biography*, vol. iv. (4th ed., 4 vols., 1853). See G. G. Perry, *Life of Henry Hammond* (1862).

HAMMOND, JOHN HAYS (1855-), American mining engineer, was born in San Francisco (Calif.), on March 31, 1855. He studied at the Sheffield scientific school, Yale university until 1876, and afterwards took a course at the Royal school of mines, Freiberg, Saxony. In 1880 he was engaged in the U.S. geological survey of the California gold fields, afterwards practising as consulting engineer, in which capacity he visited most of the countries of North and South America. In 1893 he became associated with Barnato Bros. and Cecil Rhodes in South Africa, acting as consulting engineer for the Consolidated Gold Fields Company of South Africa, the British South Africa Company, and the Randfontein Estates Gold Mining Company. As one of the leaders of the Rand faction, he was, in January, 1896, after the Jameson raid, arrested and condemned to death, but the sentence was commuted, and later he was released on payment of a \$125,000 fine. In 1900 he returned to the United States and be-

came largely interested in mining properties and irrigation projects both in the United States and Mexico. He was president of the Panama Pacific Exposition commission to Europe, 1912; chairman of the World Court commission, 1914-15; and chairman of the U.S. coal commission, 1922-23. In 1903 he became general manager and consulting engineer of the Guggenheim Exploration Company. In 1911 he was special ambassador to represent the U.S. Government at the coronation of King George V.

His son, **JOHN HAYS HAMMOND, JR.** (1888-), American inventor, was born in San Francisco (Calif.), on April 13, 1888. He studied at the Sheffield scientific school, Yale university, from which he graduated in 1910. Devoting himself to electrical developments and experiment, he invented a torpedo for coast defence controlled by wireless energy, a system of radio control of ships and a system of selective radio telegraphy, an improvement for pipe organ mechanisms, and a new type of reflecting modulator for pianos.

HAMMOND, JOHN LAWRENCE LE BRETON (1872-), British author and journalist, was educated at Bradford grammar school and St. John's college, Oxford. He was editor of the *Speaker* from 1899 to 1906, when he joined the staff of the *Tribune* as leaderwriter. In 1907 he was appointed secretary to the civil service commission. He served in the World War with the Lowland division (Sept. 1915 to Aug. 1916), and on his discharge obtained a post in the ministry of reconstruction. Hammond is the historian of the industrial revolution in England; in his works on this subject, which are indispensable to the student, he had the assistance of his wife Barbara Hammond. His chief journalistic work was done on the *Manchester Guardian*. His publications include: *Charles James Fox* (1903); *The Village Labourer, 1760-1832* (1911, and later eds.); *The Town Labourer 1760-1832* (1917); *The Skilled Labourer 1760-1832* (1919); *Lord Shaftesbury* (1923); *The Rise of Modern Industry* (1925). He was one of the authors of *Liberalism and the Empire* (1900), and collaborated in *Essays on Liberalism by Six Oxford Men* (1900).

HAMMOND, a city of Lake county, Ind., U.S.A., on Lake Michigan and the Grand Calumet and the Little Calumet rivers, 18m. S.E. of the Chicago "Loop." It is on 9 marked highways, including Federal route 41 and the Indianapolis boulevard, the main thoroughfare into Chicago from the south-east, over which 25,000 vehicles pass daily; it is served by the Chesapeake and Ohio, the Chicago, Indianapolis and Louisville, the Erie, the Michigan Central, the New York Central, the Nickel Plate and the Pennsylvania railways and by four industrial belt lines. Two miles south is the Hammond Ford air-port (1,440ac. of level ground, thoroughly equipped and lighted) from which there is regular freight, passenger and mail service to Detroit and Chicago. The population was 36,004 in 1920 (22.5% foreign-born white) and was estimated locally at 65,000 in 1928. Hammond is one of the fast growing cities in the important industrial district around the foot of Lake Michigan known as the Calumet region. It has an area of 27 sq.m., and directly adjoins the cities of Whiting, East Chicago and Calumet city. Manufacturing industries had an output in 1925 valued at \$50,874,473. Chief among them are the building of freight and passenger railroad cars, which employs 3,000 men, steel fabrication, oil refining, printing and book-binding, and the manufacture of railroad equipment, chemicals, surgical instruments, prepared stock-feeds and pianos. Several railroads have repair shops here, and there are large iron and brass foundries. A steel plant (designed to employ 15,000 men) is under construction (1928) on a 1,300ac. site. Clearings in 1927 amounted to \$298,404,000, and the assessed valuation of property was \$85,-818,475.

Hammond dates from 1868, when George H. Hammond of Detroit established a packing plant here. The settlement at first was called State-Line, but in 1873 the name was changed to honour Hammond. It was chartered as a city in 1883. In 1890 the population was 5,428. By 1900 it was 12,376, and Hammond had become the principal slaughtering and meat-packing centre in Indiana. A little later the removal of one plant caused the loss of this position and a temporary reduction in the aggregate volume

of manufacturing, but this was more than compensated after 1905 by the establishment of new industries to which the present development is due. In 1910 the population had reached 20,925, and in the following decade it increased 72%. The factory output increased 147% in the ten years between 1915 and 1925.

HAMMONTON, a town of Atlantic county, N.J., U.S.A., midway between Philadelphia and Atlantic City, on the Lincoln highway, and served by the Pennsylvania and the Reading railways. The population was 6,417 in 1920 (26% foreign-born white) and was estimated locally at 10,000 in 1928. It is in a fertile region producing especially peaches, berries and poultry; and its manufactures include shoes, clothing, macaroni, cigars, canned fruits, tapestry and cut-glass ware.

HAMMURABI, 6th king of the Amoritic or West Semitic dynasty of Babylonia, reigned 43 years, 2067–2025 B.C. and is one of the most illustrious figures of ancient history. The so-called 1st Babylonian dynasty was founded by Sumu-abu in 2169 B.C. at Babylon, which thus was raised from an unimportant town on the eastern bank of the Euphrates to the dignity of a capital, and a rival of the far more ancient and greater city, Kish, 8 m. to the east. The invasion of Babylonia by the Canaanitic race of the west had already resulted in the founding of a West Semitic dynasty at Isin in 2301 B.C., a city in southern Sumer, which, until the rise of the Canaanitic kingdom of Babylon, shared with Ellasar the control of Sumer and Accad. At first, the kingdom founded at Babylon by this ancestor of the famous line of 11 kings at Babylon had control of only a small region north and south of the capital, and under the first two kings there was even a rival kingdom at Kish, only 8 m. away. During the reigns of Hammurabi's five predecessors the kingdoms of Isin and Ellasar successfully maintained control of the whole southern area of Babylonia; and Sinmuballit, predecessor of Hammurabi, conquered and put an end to the kingdom of Isin with the aid of Rim-Sin of Ellasar, in 2076, or only nine years before Hammurabi came to the throne, only to lose it again to Rim-Sin, the powerful king of Ellasar, seven years later, and Hammurabi himself did not gain control of the whole of Babylonia and put an end to the kingdom of Rim-Sin until his 30th year (2038).

Although his father, Sinmuballit, had largely succeeded in bequeathing to his illustrious son the united control of Sumer and Accad, the military and political achievement of Hammurabi in finally establishing a central and efficient Government at Babylon, which included not only Sumer and Accad, but extended northward to the central provinces of the Tigris and Euphrates, must be regarded as one of the most far-reaching events in ancient history. Henceforth Babylon was to be the political and intellectual centre of West Asiatic history right down to the Christian era. His name is particularly associated with the great law code promulgated for the use of the courts throughout the empire. The only fairly complete text of this Semitic code was found at Susa, inscribed on a diorite stela 8 ft. high, which had been taken to Elam as plunder by invaders during the later period of Babylon's decline, probably in the period of the Pashe dynasty (12th–11th centuries). The text is inscribed in 21 horizontal columns on the obverse beneath a bas relief of the king, who stands in attitude of prayer before the seated sun god (Shamash), who delivers to Hammurabi the laws of the kingdom, a *motif* undoubtedly connected with the legend of Moses and the revelation of the Decalogue from Yahweh on Mt. Sinai. The last five or six columns of the obverse have been defaced by the Elamitic invader, who probably intended to inscribe here a relation of his conquest of Babylon. The reverse is complete and carries 28 horizontal columns. The first four columns and top of column five of the obverse, contain the prologue, which is the principal source for Hammurabi's extensive restorations of the temples and cults of Babylonia and Assyria. The last five columns of the reverse contain the epilogue, a glorification of the mighty works of peace executed by Hammurabi. Sixty-five laws are contained on the obverse, and about 40 laws are defaced at the bottom; the reverse contains 183 laws. Fragments of the code as redacted on a series of tablets for use at Nippur in the same period have been excavated there, and fragments of an Assyrian copy of the 7th cen-

tury were found at Nineveh. These partially restore the great gap in the Susa stela.

Hammurabi is generally identified with Amraphel, king of Shinar, who with Arioch of Ellasar, Cheodorla'omar of Elam and Tidal, king of Goiim, invaded Canaan in the days of Abraham. Since Hammurabi apparently enjoyed peaceful relations with the powerful Elamitic king, Rim-Sin of Ellasar, and his father, Kudur-mabug, *ad-da* of Emutbal and of Amurru, the biblical records appear to harmonize with these facts and the identification has never been successfully disproved.

Although no great literary or historical documents from his reign have survived, a great number of administrative documents and letters from it are known and are constantly increasing. There is little doubt but that the theological reconstruction of the Sumerian pantheon, by which the priests of Babylon raised Marduk, the local deity, to the rank of a great god, began at this time. To his and the succeeding reigns of Samsuiluna, Abi-esu', Ammiditana and Ammizaduga, may certainly be ascribed the gradual completion of the Accadian version of the Epic of Creation in six books or tablets, in which Marduk is made to displace the older Ninurta of the Sumerian legend of Creation. Hammurabi regularly employs *Sumerian* as the language of his records of temple and cult restorations and of other dedicatory inscriptions, as did all his successors.

The derivation of his name is disputed; the element *hammu*, *'ammu*, *ammu*, *ammi* is clearly the West Semitic word *'am*, "family, relative," Arabic "*uncle*," and it is characteristic of West Semitic religion to describe a deity as "father, brother, uncle." A grammatical gloss explains *hammu* by *kintu*, "family." The element *rabi* is usually explained as meaning "great," "the uncle is great." There is another king by this name of the Canaanitish kingdom of Hana, whose capital Tirga is the modern Ashârah on the middle Euphrates, near the mouth of the Habur. This name is spelled Ammurabi, and Hammurapih; the Hana kingdom is contemporary with the Cassite dynasty of Babylonia. Since the name of the famous king of Babylon is once written *Ammurapi* it has been argued that the name should be pronounced *Hammurapi*, *Ammurapi*, with the meaning "the uncle is exalted, high," but this suggestion is not generally accepted.

HAMON, JEAN LOUIS (1821–1874), French painter, was born at Plouha on May 5, 1821. In the year 1848 he made his appearance at the Salon with "Le Tombeau du Christ" (Musée de Marseille). "La Comédie humaine," which he exhibited in 1852 at the Salon turned the tide of his fortune, and "Ma soeur n'y est pas" (purchased by the emperor) obtained a third-class medal in 1853. He travelled in the East and spent some time in Italy, chiefly at Capri. Hamon died on May 29, 1874.

HAMPDEN, HENRY BOUVERIE WILLIAM BRAND, 1ST VISCOUNT¹ (1812–1892), speaker of the House

¹An earlier viscountcy was bestowed in 1776 on Robert Hampden-Trevor, 4th Baron Trevor (1706–1783), a great-grandson of the daughter of John Hampden, the patriot; it became extinct in 1824 by the death of the 3rd viscount.

of Commons, was the second son of the 21st Baron Dacre, and descended from John Hampden, the patriot, in the female line; the barony of Dacre devolved on him in 1890, after he had been created Viscount Hampden in 1884. He entered parliament as a Liberal in 1852, and for some time was chief whip of his party. He was speaker of the House of Commons from 1872 to 1884. His term of office is memorable for his action on Feb. 2, 1881, in refusing further debate on W. E. Forster's Coercion bill—a step which led to the formal introduction of the closure into parliamentary procedure. He died on March 14, 1892.

HAMPDEN, JOHN (c. 1595–1643), English statesman, the eldest son of William Hampden, of Great Hampden in Buckinghamshire, where the family is said to have been established before the Conquest, and of Elizabeth, second daughter of Sir Henry Cromwell, and aunt of Oliver, the future protector, was educated at the grammar school at Thame and at Magdalen college, Oxford. In 1613 he was admitted a student of the Inner Temple. He first sat in parliament for the borough of Grampound in 1621, representing later Wendover in the first three parliaments of Charles I., Buckinghamshire in the Short Parliament of 1640, and Wendover again in the Long Parliament. In the early days of his parliamentary career he was content to be overshadowed by Eliot, as in its later days he was content to be overshadowed by Pym and to be commanded by Essex.

In 1626 Hampden took an active part in the preparation of the charges against Buckingham. In January 1627 he was bound over to answer at the council board for his refusal to pay the forced loan. Later in the year he was committed to the gatehouse, and then sent into confinement in Hampshire, from which he was liberated just before the meeting of the third parliament of the reign, in which he once more rendered useful but unobtrusive assistance to his leaders. It was not till 1637, however, that his resistance to the payment of ship-money gained for his name the lustre which it has never since lost. (*See SHIP-MONEY.*) Seven out of the 12 judges sided against him, but the connection between the rights of property and the parliamentary system was firmly established in the popular mind. The tax had been justified, says Clarendon, who expresses his admiration at Hampden's "rare temper and modesty" at this crisis, "upon such grounds and reasons as every stander-by was able to swear was not law" (*Hist. i. 150. vii. 82*).

In the Short Parliament of 1640 Hampden led the opposition (May 4) to the grant of 12 subsidies in return for the surrender of ship-money. Parliament was dissolved the next day, and on the 6th an unsuccessful search was made among the papers of Hampden and of other chiefs of the party to discover incriminating correspondence with the Scots. In the Long Parliament, though Hampden was by no means a frequent speaker, it is possible to trace his course with sufficient distinctness. His power consisted in his personal influence, and as a debater rather than as an orator. Unwearied in attendance upon committees, he was always at hand to second Pym, whom he plainly regarded as his leader. Hampden was one of the eight managers of Strafford's prosecution. Like Pym, he was in favour of the more legal and regular procedure by impeachment rather than by attainder; and his influence secured a compromise under which Strafford's counsel were heard as in the case of an impeachment, and thus a serious breach between the two Houses was averted.

Hampden was among the opponents of episcopacy. It is not that he was a theoretical Presbyterian, but he distrusted the bishops as he distrusted the monarchy. No serious importance therefore can be attached to the offers of advancement made from time to time to Hampden and his friends. Charles would gladly have given them office if they had been ready to desert their principles. Every day Hampden's conviction grew stronger that Charles would never abandon the position which he had taken up. In August 1640 Hampden was one of the four commissioners who attended Charles in Scotland. He was a warm supporter of the Grand Remonstrance, and was marked out as one of the five impeached members whose attempted arrest brought at last the opposing parties into open collision (*see also PYM, STRODE, HOLLES and LENTHALL*). In the angry scene which arose

on the proposal to print the Grand Remonstrance, it was Hampden's personal intervention which prevented an actual conflict, and it was after the impeachment had been attempted that Hampden laid down the two conditions under which resistance to the king became the duty of a good subject. Those conditions were an attack upon religion and an attack upon the fundamental laws. There can be no doubt that Hampden fully believed that both those conditions were fulfilled at the opening of 1642.

When the Civil War began Hampden was appointed a member of the committee for safety, levied a regiment of Buckinghamshire men for the parliamentary cause, and in his capacity of deputy-lieutenant carried out the parliamentary militia ordinance in the county. He took no actual part in the battle of Edgehill. His troops in the rear, however, arrested Rupert's charge at Kington, and he urged Essex to renew the attack here, and also after the disaster at Brentford. In 1643 he was present at the siege and capture of Reading. But it is not on his skill as a regimental officer that Hampden's fame rests. In war as in peace his distinction lay in his power of disentangling the essential part from the non-essential. In the constitutional struggle he had seen that the one thing necessary was to establish the supremacy of the House of Commons. In the military struggle which followed he saw, as Cromwell saw afterwards, that the one thing necessary was to beat the enemy. He protested at once against Essex's hesitations and compromises. In the formation of the confederacy of the six associated counties, which was to supply a basis for Cromwell's operations, he took an active part. His influence was felt alike in parliament and in the field. But he was not in supreme command, and he had none of that impatience which often leads able men to fail in the execution of orders of which they disapprove. His life was sacrificed to his devotion to the call of discipline and duty. On June 18, 1643, when he was holding out on Chalgrove Field against the superior numbers of Rupert till reinforcements arrived, he received two carbine balls in the shoulder. Leaving the field he reached Thame, survived six days, and died on the 24th. He was buried in the church of Great Hampden.

Hampden married (1) in 1619 Elizabeth, daughter of Edmund Symeon of Pyrtton, Oxfordshire, and (2) Letitia, daughter of Sir Francis Knollys and widow of Sir Thomas Vachell. By his first wife he had nine children, one of whom, Richard (1631–1695), was chancellor of the exchequer in William III.'s reign; from two of his daughters are descended the families of Trevor-Hampden and Hobart-Hampden, the descent in the male line becoming apparently extinct in 1754 in the person of his grandson John Hampden.

See S. R. Gardiner's Hist. of England and of the Great Civil War; the article on Hampden in the Dict. of Nat. Biography, by C. H. Firth, with authorities there collected; Clarendon's Hist. of the Rebellion; Sir Philip Warwick's Mem., p. 239; Wood's Ath. Oxon., iii. 59; Lord Nugent's Memorials of John Hampden (1831); Macaulay's Essay on Hampden (1831). The printed pamphlet announcing his capture of Reading in Dec. 1642 is shown by Firth to be spurious, and the account in *Mercurius Aulicus*, January 27 and 29, 1643, of Hampden commanding an attack at Brill, to be also false, while the published speech supposed to be spoken by Hampden on Jan. 4, 1642, and reproduced by Forster in the *Arrest of the Five Members* (1660), has been proved by Gardiner to be a forgery (*Hist. of England*, x. 135). Firth has also shown, in *The Academy* for 1889, Nov. 2 and 9, that "the belief that we possess the words of Hampden's last prayer must be abandoned."

HAMPDEN, JOHN (c. 1656–1696), the second son of Richard Hampden (1631–1695), returned to England after residing for about two years in France, and joined himself to Lord William Russell and Algernon Sidney and the party opposed to the arbitrary government of Charles II. With Russell and Sidney he was arrested in 1683 for alleged complicity in the Rye House plot; as he could not pay the fine of £40,000 imposed upon him he remained in prison. In 1685, after the failure of Monmouth's rising, Hampden was again brought to trial, and on a charge of high treason was condemned to death. But the sentence was not carried out, and having paid £6,000 he was set at liberty. In the Convention parliament of 1689 he represented Wendover. He died by his own hand on Dec. 12, 1696. Bishop Burnet, who was one of his friends, described him as "one of the learnedest gentlemen I ever knew."

HAMPDEN, RENN DICKSON (1793–1868), English divine, bishop of Hereford, was born in Barbados, where his father was colonel of militia, and was educated at Oriel College, Oxford. After holding various curacies he returned to Oxford in 1829 and was Bampton lecturer in 1832. His lectures, *The Scholastic Philosophy in its relation to Christian Theology*, were printed in 1833. He became principal of St. Mary's Hall (1833), professor of moral philosophy (1834) and Regius professor of divinity (1836). His nomination by Lord John Russell to the vacant see of Hereford in 1847 was the signal for a violent and organized opposition on account of his supposed Arian leanings; and his consecration in March 1848 took place in spite of a remonstrance by many of the bishops and the resistance of Dr. John Merewether, the dean of Hereford, who voted against the election when the *congé d'élire* reached the chapter. Among the more important of Hampden's later writings were the articles on Aristotle, Plato and Socrates, contributed to the eighth edition of the *Encyclopædia Britannica*, and afterwards reprinted with additions under the title of *The Fathers of Greek Philosophy* (Edinburgh, 1862). He died in London on April 23, 1868.

See Henrietta Hampden, *Some Memorials of R. D. Hampden* (1871).

HAMPDEN, WALTER (1879–), American actor, was born in Brooklyn, N.Y., on June 30, 1879. After graduating from Brooklyn Polytechnic institute in 1900 he spent a year in study at Paris and then joined Frank R. Benson's company in classical repertoire in England, where he made his first stage appearance. With this company, then noted as a training school for actors, Hampden remained three years, playing more than 70 rôles, chiefly in Shakespearian plays. Following this he was engaged for three seasons as leading man in the Adelphi theatre, London, where in 1905 he first acted Hamlet, succeeding the younger Irving in the rôle. Returning to America in 1907 he created an impression by his rendition of the title rôles in *The Master Builder* and *The Servant in the House*. Later he gave important performances in *The Yellow Jacket*, *Salome*, *The Tempest* and *The Wayfarer* and gained wider recognition by his tours in Shakespearian repertoire. In 1923–24 he revived *Cyrano de Bergerac*. In 1925 he leased the old Colonial theatre, in which he gave notable performances of *Hamlet* and *The Merchant of Venice* in 1925–26, *The Immortal Thief* and *Caponasacchi* in 1926–27 and *The Enemy of the People* in 1927–28. As a Shakespearian actor Hampden is ranked high, and his representation of Hamlet was generally characterized by dramatic critics as the finest in America since that of Edwin Booth.

HAMPDEN-SIDNEY, a village of Prince Edward county, Virginia, U.S.A., 70m. S.W. of Richmond, with a population of about 350 in 1928. The nearest railroad station is Farmville, 6m. N.W., on the Norfolk and Western railway. It is the seat of Hampden-Sidney college, founded as an academy in 1775 by the Presbytery of Hanover, and incorporated as a college in 1783. Among the incorporators were Patrick Henry and James Madison. Many of its graduates have been prominent in public life and as educators and preachers.

HAMPSHIRE or COUNTY OF SOUTHAMPTON (abbreviated Hants.), a southern county of England, bounded north by Berkshire, east by Surrey and Sussex, south by the English Channel and west by Dorsetshire and Wiltshire. The area is 1,623.5 square miles. Pop. (1921), 1,004,918. It is the county which has grown around the maritime entries of Southampton Water and the Christchurch Avon. Its jurisdiction has spread over the hills to the north almost as far as the Kennet, the adjoining county of Berkshire northward having grown valleywards both north and south of the White Horse hills.

Geology.—Somewhat to the north of the centre of the county is a broad expanse of hilly chalk country included in the western downs and exceeding 850 ft. in the Beacon and other hills; the whole of it has been folded, the dip to the north being steeper than that to the south. In the north the chalk disappears beneath Tertiary strata of the London basin, and some little distance south of Winchester it runs in a similar manner beneath the Tertiaries of the Hampshire basin. Scattered here and there over the chalk are small outlying remnants which show that the

two Tertiary areas were once continuous. The lower Greensand is represented by sandstones and limestones, forming the high ridge that runs on towards Hindhead, then by the sands and clays of the Sandgate beds which lie in the low ground west of the ridge, and finally by the Folkestone beds; all these dip westward beneath the gault. Between the gault and the chalk is the Upper Greensand, with a hard bed of calcareous sandstone, which stands up in places as a prominent escarpment. A gentle anticline brings up the chalk through the Tertiary rocks near Fareham. The Tertiary rocks of the north (London basin) about Farnborough, Aldershot and Kingsclere, comprise the Reading beds and London clay, often covered by heathy commons of the more sandy Bagshot beds. The southern Tertiary rocks of the Hampshire basin include the Lower Eocene Reading beds—used for brick-making—and the London clay, which extend from the boundary of the chalk by Romsey, Bishop's Waltham, to Havant. These are succeeded towards the south by Upper Eocene beds, the Bracklesham beds and the Barton clay. The Barton clays are rich in fossils, and the Bagshot beds at Bournemouth contain numerous remains of subtropical plants. Clays and sands of Oligocene age (unknown in the London basin) are found near Lymington, Brockenhurst and Beaulieu; they include the Headon beds, with a fluviomarine fauna, well exposed at Hordwell cliffs, and the marine beds of Brockenhurst.

The Solent and the Spithead, which now separate the Isle of Wight from the mainland, are thought to mark the lower course of a river the upper valley of which approximated to that of the present river Frome. Southampton Water, Christchurch bay, and the channels separating Hayling and Portsea islands are further evidences of submergence. Rivers, once tributaries in a greater system, now find their way independently to the sea. The river Avon, in the south-west, rises in Wiltshire, and is joined by the Stour close to its mouth below Christchurch. The Lymington or Boldre river rises in the New Forest and enters the Solent through Lymington creek. The Beaulieu in the eastern part of the forest also enters the Solent. The Test rises near Overton in the north, and after its junction with the Anton at Fullerton passes Stockbridge and Romsey, and enters the head of Southampton Water, which also receives the Itchen and the Hamble. The Wey, the Loddon and the Blackwater, rising in the north-eastern part of the county, bring that part into the basin of the Thames. The streams from the chalk hills run clear and swift, and the trout-fishing in the county is famous. Salmon are taken in the Avon.

History.—The few prehistoric beaker-pots found on the chalk hills of Hampshire may be connected with those of Wiltshire, or may indicate penetration from the coast. (See Fox, *Arch. Camb.*, 1928.) Later, Southampton Water and the Christchurch Avon, with easy access to the chalk downs, encouraged maritime intercourse. Palstaves from Bitterne, near Southampton, and from the New Forest, together with a type of socketed celt found in a hoard at Ventnor in the Isle of Wight, can be matched by many finds in north-west France, and may have been objects of early trade. (See Crawford, "Prehistoric Trade between England and France," *L'Anthropologie*, 1913.) La Tène I. brooches from Winchester and Shoddesdon farm, Weyhill, suggest a continuation of this trade for many centuries. (See Fox, *Arch. Camb.*, 1927.) The finds at Hengistbury (Christchurch) also point to trade with an iron-using people in south-west France. (See Bushe-Fox, "Excavations at Hengistbury Head, Hants," *R.R.C.S.A.*, 1915.)

The earliest English settlers, a Jutish tribe, occupied the northern parts of the Isle of Wight and the valleys of the Meon and the Hamble. Their settlements were, however, soon absorbed in the territory of the West Saxons, who in 495 landed at the mouth of the Itchen under the leadership of Cerdic and Cynric. After the battle of Charford in 519 the district was organized as West Saxon territory, and thus became the nucleus of the later kingdom of Wessex. The Northmen first attacked the Hampshire coast in 835, and made their headquarters in the Isle of Wight. Hampshire suffered less from the Conquest than almost any English county, and was a favourite resort of the Norman kings.

The alleged destruction of property for the formation of the New Forest is refuted by the Domesday record, which shows that this district had never been under cultivation. Hampshire is first mentioned in the Saxon Chronicle in 755, when the boundaries were practically those of the present day. The Domesday survey mentions 44 hundreds in Hampshire, but by the 14th century the number had been reduced to 37. The hundreds of East Medina and West Medina in the Isle of Wight are mentioned in 1316. Constables of the hundreds were first appointed by the Statute of Winchester in 1285, and the hundred court continued to elect a high constable for Fordingbridge until 1878. The chief court of the Isle of Wight was the Knighten court, held at Newport every three weeks. The sheriff's court and the assizes and quarter sessions for the county were formerly held at Winchester, but in 1831 the county was divided into 14 petty sessional divisions; the quarter sessions for the county were held at Andover; and Portsmouth, Southampton and Winchester had separate jurisdiction. Southampton was made a county by itself with a separate sheriff in 1447.

In the middle of the 7th century Hampshire formed part of the West Saxon bishopric of Dorchester-on-Thames. On the transference of the episcopal seat in 676 it was included in the diocese of Winchester. In 1291 the archdeaconry of Winchester was coextensive with the county and comprised ten rural deaneries. In 1850 the Isle of Wight was subdivided into the deaneries of East Medina and West Medina. In 1871 the archdeaconry of the Isle of Wight was constituted, and in 1892 was divided into the deaneries of East Wight and West Wight. The historic diocese of Winchester has recently been divided (1924-7), separate bishoprics of Guildford and Portsmouth being created.

Wool and cloth manufactures prospered at Winchester in the 12th century and survived till within recent years. Salt-making and the manufacture of iron from native ironstone also flourished from pre-Norman times until the 19th century. In the 14th century Southampton traded with Venice, and from the 15th to the 18th century many warships were constructed in its docks. Silk-weaving was formerly carried on at Winchester, Andover, Odiham, Alton, Whitchurch and Overton, the first mills being set up in 1684 at Southampton by French refugees. The paper manufacture at Laverstoke was also started by Huguenot refugees.

Antiquities.—The monastery of Hyde, near Winchester, the churches of Christchurch and Romsey, the ruins of Netley abbey, and of Beaulieu abbey in the New Forest, the fragments of the priory of St. Denys, Southampton, the church at Porchester and the slight ruins at Titchfield, near Fareham, and Quarr abbey in the Isle of Wight are treated separately. Other foundations, of which the remains are slight, were the Augustinian priory of Southwick near Fareham, founded by William of Wykeham; that of Breamore, founded by Baldwin de Redvers, and that of Motisfont near Romsey, endowed soon after the Conquest. Pre-Conquest work is well shown in the churches of Corhampton and Breamore, and very early masonry is also found in Headbourne Worthey church. The most noteworthy Norman churches are at Chilcombe and Kingsclere and (with Early English additions) at Brockenhurst, Upper Clatford, which has the unusual arrangement of a double chancel arch, Hambledon, Milford and East Meon. Principally Early English are the churches of Cheriton, Grately, which retains some excellent contemporary stained glass from Salisbury cathedral; Sopley, which is partly Perpendicular, and Thruxton. The frescoes in Bramley church, ranging in date from the 13th to the 15th century, include a representation of the murder of Thomas à Becket. A fine series of Norman fonts in black marble occurs in Winchester cathedral and the churches of St. Michael, Southampton, East Meon and St. Mary Bourne.

The most notable castles are Carisbrooke, in the Isle of Wight; Porchester, a fine Norman stronghold embodying Roman remains, on Portsmouth harbour; and Hurst, guarding the mouth of the Solent.

Agriculture and Industries.—In 1926, 561,348 ac. (excluding the Isle of Wight) were under crops and grass, of which 312,770 ac. were arable land. Oats, wheat, turnips and swedes, barley and mangolds are the principal crops; 53,480 ac. are given

over to clover and grasses. Barley is usually sown after turnips, and is grown in the uplands. Rotation grasses are grown chiefly in the uplands. Sanfoin is the grass best adapted to a calcareous subsoil. In the lower levels no sanfoin and scarcely any clover is grown, the hay being supplied from the rich water meadows, where the grasses are fit for pasture before any traces of vegetation appear in the surrounding fields. Hops are grown in the eastern part of the county, bordering on Surrey. Owing to the varieties of soil the rotation observed is very diversified. Most of the farms are large, and there are a number of model farms. The waste land has been mostly brought under tillage, but a very large acreage of the ancient forests is still occupied by wood. In addition to the New Forest there are in the east Woolmer forest and Alice Holt, in the south-east the forest of Bere and Waltham Chase, and in the Isle of Wight, Parkhurst forest. The honey of the county is celebrated. Much attention is paid to the rearing of sheep and cattle. The original breed of sheep was white-faced with horns, but most of the flocks are now of a Southdown variety and are known as "short wools" or "Hampshire downs." The breeding and rearing of horses is widely practised. In the vicinity of the forest pigs are fed on acorns and beechmast.

Portsmouth and Gosport are naval centres. Southampton is one of the principal ports in the kingdom. Fancy pottery and terra-cotta are made at Fareham and Bishop's Waltham. At most of the coast towns fishing is carried on, and there are oyster beds at Hayling Island. Cowes in the Isle of Wight is the station of the Royal Yacht squadron, and has building yards. The principal seaside resorts besides those in the Isle of Wight are Bournemouth, Milford, Lee-on-the-Solent, Southsea and South Hayling. Aldershot is the principal military training centre in the British Isles.

Communications are provided mainly by the lines of the Southern railway company, which also owns the docks at Southampton. The main line serves Farnborough, Basingstoke, Whitchurch and Andover, and a branch diverges southward from Basingstoke for Winchester, Southampton and the New Forest and Bournemouth. An alternative line from eastward to Winchester serves Aldershot, Alton and Alresford. The main Portsmouth line skirts the south-eastern border by Petersfield to Havant. There are large workshops at Eastleigh, near Southampton. The G.W.R. company serves Basingstoke from Reading and Whitchurch, Winchester and Southampton from Didcot. The Somerset and Dorset line connects Bournemouth with Bath.

The administrative county of Hampshire returns six members to parliament, the divisions being Aldershot, Basingstoke, Fareham, New Forest and Christchurch, Petersfield and Winchester. The administrative county of the Isle of Wight returns one member. The county borough of Bournemouth returns one member, Portsmouth three members and Southampton two members. There are 11 municipal boroughs and 16 urban districts. Separate courts of quarter-sessions are held at Andover, Bournemouth, Portsmouth, Southampton and Winchester.

HAMPSTEAD, a north-western metropolitan borough of London, England, bounded E. by St. Pancras and S. by St. Marylebone, and extending N. and W. to the boundary of the county of London. Pop. (1921) 86,153. The name, *Hamstede*, is synonymous with "homestead," and the manor is first named in a charter of Edgar (957-975), and was granted to the abbey of Westminster by Ethelred in 986. It reverted to the Crown in 1550, and then had various owners.

The surface of the ground is sharply undulating, an elevated spur extending south-west from the neighbourhood of Highgate, and turning south through Hampstead reaches a height of 443 ft. above the level of the Thames. The Edgware road bounds Hampstead on the west. The heath is a fine open space of about 240 acres, including in its bounds the summit of Hampstead hill. It is sandy, in parts well wooded, diversified with several small sheets of water, and to a great extent preserves its natural characteristics unaltered. Of all the public grounds within London this is the most valuable to the populace at large. In 1871 its preservation as an open space was insured, when the lord of the manor gave up his rights. An act of parliament transferred the

ownership to the Metropolitan Board of Works, to which body the London county council succeeded. The heath is continued eastward in Parliament hill (borough of St. Pancras), acquired for the public in 1890; and westward in Golders Hill park: a further extension which is now public property is Kenwood. A Protection Society guards the preservation of the heath. Hampstead has long been a favourite residential quarter, especially for lawyers, artists and men of letters. Among famous residents are found the first earl of Chatham, John Constable, George Romney, George du Maurier, Joseph Butler, author of the *Analogy*, Sir Richard Steele, John Keats, the sisters Joanna and Agnes Baillie, Leigh Hunt and many others. Chatham's residence was at North End; here also Wilkie Collins was born. Three old-established inns are the Bull and Bush, the Spaniards, and Jack Straw's Castle; the Upper Flask inn, now a private house, was the meeting-place of the Kit-Cat club. Chalybeate springs were discovered at Hampstead in the 17th century, and early in the 18th rivalled those of Tunbridge Wells and Epsom, but their fame is lost.

In the south-east Hampstead includes the greater part of Primrose hill. The borough has in all about 350 acres of open spaces. The parliamentary borough of Hampstead returns one member.

HAMPTON, WADE (1818-1902), American cavalry leader was born on March 28, 1818 at Columbia, S.C., the son of Wade Hampton (1791-1858), one of the wealthiest planters in the South, and the grandson of Wade Hampton (1754-1835), a captain in the American Revolution and a brigadier-general in the War of 1812. He graduated in 1836 at South Carolina college, and was trained for the law. He devoted himself, however, to the management of his great plantations in South Carolina and in Mississippi, and took part in state politics and legislation. Though his own views were opposed to the prevailing state-rights tone of South Carolinian opinion, he threw himself heartily into the Southern cause in 1861, raising a mixed command known as "Hampton's Legion," which he led at the first battle of Bull Run. During the Civil War he served in the main with the army of Northern Virginia in Stuart's cavalry corps. After Stuart's death Hampton distinguished himself greatly in opposing Sheridan in the Shenandoah valley, and was made lieutenant-general to command Lee's whole force of cavalry. In 1865 he assisted Joseph Johnston in the attempt to prevent Sherman's advance through the Carolinas. After the war his attitude was conciliatory and he recommended a frank acceptance by the South of the war's political consequences. He was governor of his state in 1876-79, being installed after a memorable contest; he served in the U.S. Senate in 1879-91, and was United States commissioner of Pacific railways in 1893-97. He died at Columbus, on April 11, 1902.

See E. L. Wells, *Hampton and Reconstruction* (Columbia, S.C., 1907).

HAMPTON, an urban district of Middlesex, England, 15 m. S.W. of St. Paul's cathedral, London, on the river Thames, served by the S.R. Pop. (1921) 10,675. Close to the river, a mile below the town, stands Hampton Court palace, one of the finest specimens of Tudor architecture, and formerly a royal residence. It was erected by Cardinal Wolsey, who in 1515 received a lease of the old mansion and grounds for 99 years, and he presented the mansion to Henry VIII. in 1526. It became Henry's favourite residence, and he added to the building the great hall and chapel in the Gothic style. Of the original five quadrangles only two remain, but a third was erected by Sir Christopher Wren for William III. In 1649 the manor was sold to a private owner but immediately after came into the hands of Cromwell; and Hampton Court continued to be a royal residence until the time of George II. It was the meeting-place (1604) of the conference held to settle the dispute between the Presbyterians and the state clergy. The state apartments and picture galleries are open to the public. The gardens, laid out in the Dutch style favoured by William III., contain a vine planted in 1768. In the enclosure north of the palace (the Wilderness) is the Maze, a favourite resort. North again lies Bushey park, legally a royal demesne (1,000 acres).

HAMPTON, a city of south-eastern Virginia, U.S.A., 15m.

N.W. of Norfolk, on Hampton Roads, at the mouth of the James river; the county seat of Elizabeth City county. It is served by the Chesapeake and Ohio railway and by ferries to Norfolk. The population was 6,138 in 1920 (35% negroes) and was estimated locally at 8,000 in 1928. The city ships large quantities of oysters, fish, crab meat, and garden truck. It is the seat of the Hampton Normal and Agricultural Institute (for negroes and Indians), founded in 1868 by the American Missionary Association and chartered independently in 1870. The institute has been a very influential factor in the development of educational theories and opportunities for negroes, training many of their leaders (including Booker T. Washington), publishing *The Southern Workman*, and stimulating the establishment of numerous other industrial schools on the same principles. Langley field, headquarters of the Second Wing of the Army Air Corps and of the Air Corps Tactical school, is at Hampton; and at Ft. Monroe, which guards the entrance to Hampton Roads, 3m. S.E., is the Coast Artillery school. There is a branch of the National Home for Disabled Volunteer Soldiers at Hampton, and a national cemetery containing over 13,000 graves. Hampton was settled in 1610 on the site of an Indian village, Kecoughtan, a name it kept for some time, and was represented at the first meeting of the Virginia House of Burgesses in 1619. It was incorporated as a town in 1887, and became a city in 1908. Since 1920 it has had a commission-manager form of government. It was fired by the British in the war of 1812, and by the Confederates in Aug. 1861. During the Civil War a large Union hospital was maintained here in the building of a college established in 1857. St. John's church, built in the year 1727, has the original communion set presented by the Crown.

HAMPTON ROADS, a channel through which the waters of the James, Nansemond and Elizabeth rivers of Virginia, U.S.A., pass (between Old Point Comfort to the north and Sewell's Point to the south) into Chesapeake bay. It is an important highway of commerce, especially for the cities of Norfolk, Portsmouth and Newport News, and is one of the chief rendezvous of the U.S. navy. The entrance from Chesapeake bay is defended by Ft. Monroe on Old Point Comfort and by Ft. Wood on a small island near the middle of the channel. At Portsmouth, a few miles up the Elizabeth river, is an important navy-yard. Hampton Roads is noted historically as the scene (March 9, 1862) of the first battle between iron-clad vessels (see MONITOR and MERRIMAC, BATTLE OF). On Feb. 3, 1865, near Ft. Monroe occurred the meeting on board a steamer of President Lincoln and Secretary Seward with the Confederate commissioners, which is known as the Hampton Roads Conference. At Sewell's Point, on Hampton Roads, during the year 1907, was held the Jamestown Tercentennial Exposition.

HAMSTER, a European mammal of the order Rodentia, *Cricetus cricetus* belonging to the mouse tribe, *Muridae*, in which it typifies the sub-family *Cricetinae*. (See RODENTIA.) The hamsters are short-tailed rodents, with large cheek-pouches; the largest is the common *C. cricetus*. Their geographical distribution comprises Europe and Central Asia. Most of the European hamsters show more or less black on the under-parts, but the small species from Greece and Central Asia (*Cricetulus*) are uniformly grey. The common species constructs elaborate burrows containing several chambers, one of which is employed as a granary, and filled with corn for winter use. As a rule, the males, females, and young of the first year occupy separate burrows. During the winter these animals retire to their burrows, awakening about February or March. They are very prolific, the female producing several litters in the year, each consisting of over a dozen blind young; and these, when three weeks old, are turned out to form underground homes for themselves. The burrow of the adult descends 4 or 5 ft. beneath the surface; on retiring for the winter the hamster closes the entrances. Although feeding chiefly on roots, fruits and grain, it eats small quadrupeds, lizards and birds. It is fierce and pugnacious, the males fighting for possession of the females. Their numbers are kept in check by foxes, dogs, cats and pole-cats. The skin of the hamster is of some value, and its flesh is used as food. America, especially North America, is the home

of the majority of *Cricetinae*. They are divided into about two dozen genera and the number of species is very large indeed. Both in size and form considerable variability is displayed; the majority of the species are, however, mouse-like, as in the genera *Peromyscus* (white-footed mice) and *Oryzomys* (rice-rats). The subfamily also contains the American Grasshopper Mice *Onychomys*, and Harvest Mice (*Reithrodontomys*). The Florida cotton-rat (*Sigmodon hispidus*) is another representative of the group. In the Old World the subfamily is represented by about six genera, three of which *Cricetulus*, *Cricetus*, and *Mesocricetus* are European, and one (*Mystromys*) is African.

HAMSUN, KNUT (1859–), Norwegian author, was born on Aug. 4, 1859, at Lom in the Gudbrandsdal valley, the son of poor parents. He started to write at the age of 19 when he was a shoemaker's apprentice at Bodö in north Norway, and for the next ten years earned his livelihood in various ways, e.g., as coal trimmer and country schoolmaster. He eventually went to America, where he became a tram conductor in Chicago and a farm labourer on the prairies. In 1888 he published, in a Danish magazine, the fragment of a novel, *Sult*, which was later translated into English, as *Hunger*. This work at once attracted attention by the beauty of style and originality of treatment. His works from this time onward revealed a richness of talent which rapidly increased his reputation. He is akin to the Russians in his psychological analysis of morbid types, but the American influence is apparent in his use of startling metaphors and the aptness of his expressions. An intense love of nature characterizes his work. He is chiefly known to the English-speaking world by three novels, *Hunger*, *Growth of the Soil* and *The Woman at the Well*. In 1920 Hamsun was honored with the award of the Nobel Prize for literature.

HAMTRAMCK, a city of Wayne county, Michigan, U.S.A., completely surrounded by Detroit. The population was 48,615 in 1920, and was estimated locally at 60,000 in 1928, of whom about 45,000 were of Polish birth or parentage. It is an important manufacturing community, making chiefly automobiles and their accessories. The output of its 24 factories in 1925 was valued at \$263,285,887, and in 1927 the assessed valuation of property was \$117,177,128. In 1901 a portion of Hamtramck township was organized as a village, consisting then of two factories and a few scattered houses. By 1910 it had a population of 3,559, and in the next ten years that figure was multiplied by 14. In 1922 it was incorporated as a city. Township and city were named after Colonel John Francis Hamtramck, the first American commander of the fort at Detroit after the British troops surrendered it in 1796.

HAMY, ERNEST THÉODORE (1842–1908), French anthropologist and ethnographer, was born at Boulogne-sur-mer on June 22, 1842. He studied medicine in Paris under Quatrefages, with whom he collaborated in his famous *Crania Ethnica les crânes des races humaines* (1875–82). In 1880 he founded the Ethnological museum in the Trocadero, and acted as director until 1892, when he was appointed professor. Hamy devoted himself to research on the Mexican races and the South African tribes, and concluded that the Hottentots are the result of an ancient cross between these two races. He died in Paris on Nov. 18, 1908. Besides the above-mentioned work, he wrote: *Anthropologie du Mexique* (1884, seq.), *Decades Americanae* (1899–1902), *Études historiques et géographiques* (1896), *Joseph Debey* (1905), *Aimée Bonpland* (1906), and edited *Lettres Américaines d'Alex. Humboldt* (1905).

HANAPER, a basket to contain a "hanap," i.e., a goblet with a stem. The famous Royal Gold Cup in the British Museum is called a "hanap" in the inventory of Charles VI. of France. The wicker basket in which were kept writs and other documents in the chancery was called a "hanaper," and hence it became the name of a department of the chancery, now abolished, under an officer known as the clerk of the hanaper, into which were paid fees for the sealing of charters, patents, writs, etc., and from which issued certain writs under the great seal.

HANAU, a town in the Prussian province of Hesse-Nassau, on the right bank of the Main, 14 m. by rail E. from Frankfurt

and at the junction of lines to Friedberg, Bebra and Aschaffenburg. Pop. (1925) 38,498.

From the number of finds near Hanau, it would appear that it owes its origin to a Roman settlement. It received municipal rights in 1393, and in 1528 it was fortified and the castle rebuilt. At the end of the 16th century its prosperity received considerable impulse from the accession of the Walloons and Netherlanders. Early in the 15th century Hanau became the capital of a principality of the Empire, and in 1785 the province was united to Hesse-Cassel. In 1803 it again became an independent principality. In 1815 it reverted to Hesse-Cassel, and in 1866 it was joined to Prussia.

The streets of the old town are narrow and irregular, but the new, founded at the end of the 16th century by fugitive Walloons and Netherlanders, is built in the form of a pentagon with broad streets crossing at right angles. Among the principal buildings are the ancient castle, formerly the residence of the counts of Hanau, who are buried in the old church of St. Mary; the church of St. John, dating from the 17th century, with a handsome tower, and the church in the new town, built by the Walloons in the beginning of the 17th century in the form of two intersecting circles. Hanau is the birthplace of the brothers Grimm, to whom a monument was erected here in 1896. In the neighbourhood of the town are the palace of Philippsruhe and the spa of Wilhelmsbad. Hanau manufactures ornaments of various kinds, cigars, leather, paper, gold, silver and platinum wares, chocolate, soap, hats, gloves, machinery, chemicals and lamps. Diamond cutting is carried on and the town has also foundries and breweries. It carries on trade in wood, wine and corn, in addition to its articles of manufacture.

HANBURY WILLIAMS, SIR CHARLES (1708–1759), English diplomatist and author, was a son of Major John Hanbury (afterwards Hanbury Williams) (1664–1734), of Pontypool, Monmouthshire, and a scion of an ancient Worcestershire family. He was educated at Eton, where he made friends with Henry Fielding, the novelist. He was elected M.P. for Monmouthshire (1734–1747) and subsequently for Leominster (1754–1759). He became known as a gallant and wit about town, and wrote satirical light verse. A collection of his poems was published in 1763 and of his *Works* in 1822. In 1746 he was sent on a diplomatic mission to Dresden; and through Henry Fox's influence he was sent as envoy to Berlin (1750), Dresden (1751), Vienna (1753), Dresden (1754) and St. Petersburg (1755–1757); in the latter case he was the instrument for a plan for the alliance between England, Russia and Austria, which finally broke down, to his embarrassment. He returned to England, and committed suicide on Nov. 2, 1759, being buried in Westminster Abbey.

HANCOCK, JOHN (1737–1793), American revolutionary statesman, was born in that part of Braintree, Mass., now known as Quincy, on Jan. 23, 1737. After graduating at Harvard in 1754, he entered the mercantile house of his uncle, Thomas Hancock of Boston, who had adopted him, and on whose death, in 1764, he fell heir to a large fortune and a prosperous business. In 1765 he became a selectman of Boston, and from 1766 to 1772 was a member of the Massachusetts general court. An event which is thought to have greatly influenced Hancock's subsequent career was the seizure of the sloop "Liberty" in 1768 by the customs officers for discharging, without paying the duties, a cargo of Madeira wine consigned to Hancock. Many suits were thereupon entered against Hancock, which, if successful, would have caused the confiscation of his estate, but which undoubtedly enhanced his popularity with the Whig element and increased his resentment against the British Government. He was a member of the committee appointed in a Boston town meeting immediately after the "Boston massacre" in 1770 to demand the removal of British troops from the town. In 1774 and 1775 he was president of the first and second Provincial Congresses respectively, and he shared with Samuel Adams the leadership of the Massachusetts Whigs in all the irregular measures preceding the American Revolution. The famous expedition sent by Gen. Thomas Gage of Massachusetts to Lexington and Concord on April 18–19, 1775, had for its object, besides the destruction of materials of war at Concord, the

capture of Hancock and Adams, who were temporarily staying at Lexington, and these two leaders were expressly excepted in the proclamation of pardon issued on June 12 by Gage, their offences, it was said, being "of too flagitious a nature to admit of any other consideration than that of condign punishment." Hancock was a member of the Continental Congress from 1775 to 1780, was president of it from May 1775 to October 1777, being the first to sign the Declaration of Independence, and was a member of the Confederation Congress in 1785-86. In 1778 he commanded, as major-general of militia, the Massachusetts troops who participated in the Rhode Island expedition. He was a member of the Massachusetts Constitutional Convention of 1779-80, became the first governor of the State, and served from 1780 to 1785 and again from 1787 until his death. Although at first unfriendly to the Federal Constitution as drafted by the convention at Philadelphia, he was finally won over to its support, and in 1788 he presided over the Massachusetts convention which ratified the instrument. Hancock was not by nature a leader, but he wielded great influence on account of his wealth and social position, and was liberal, public-spirited, and, as his repeated election—the elections were annual—to the governorship attests, exceedingly popular. He died at Quincy, Mass., on Oct. 8, 1793.

See Abram E. Brown, *John Hancock, His Book* (Boston, 1898), a work consisting largely of extracts from Hancock's letters; Lorenzo Sears, *John Hancock, the Picturesque Patriot* (1912).

HANCOCK, WINFIELD SCOTT (1824-1886), American general, was born on Feb. 14, 1824, in Montgomery county, Pa. He graduated in 1844 from the Military academy and was breveted first lieutenant for "gallant and meritorious conduct" in the Mexican War. After serving in the West, in Florida and elsewhere he married in 1850 Miss Almira Russell of St. Louis; became first lieutenant in 1853, and assistant quartermaster with the rank of captain in 1855. At the outbreak of the Civil War he was ordered East at his own request and on Sept. 23, 1861, was made brig.-general of volunteers and assigned to command a brigade in the Army of the Potomac. He took part in the Peninsula campaign, and the handling of his troops in the engagement at Williamsburg on May 5, 1862, was such that McClellan reported "Hancock was superb," an epithet always afterwards applied to him. At the battle of Antietam he was placed in command of the 1st Division of the IIInd. Corps, and in November he was made major-general of volunteers, and about the same time was promoted major in the Regular Army. In the battle of Fredericksburg (*q.v.*), Hancock's division was among the troops that were ordered to storm Marye's Heights. Out of the 5,006 men in his division 2,013 fell. At Chancellorsville his division received the brunt of the attack of Lee's main army. Soon after the battle he was appointed commander of the IIInd. Corps.

In the battle of Gettysburg (*q.v.*) after the defeat of the left wing of the Army of the Potomac and the death of Gen. Reynolds, Hancock arrived on the field with orders from Meade to assume command and to decide whether to continue the fight there or to fall back. He decided to stay, and held Cemetery Hill and Ridge until the arrival of the main body of the Federal Army. During the second day's battle he commanded the left centre of the Union Army, and after Gen. Sickles had been wounded, the whole of the left wing. In the third day's battle he commanded the left centre, upon which fell the full brunt of Pickett's charge, one of the most famous incidents of the war. As the guns of the Confederate Army opened the attack Hancock rode along the front of his line to show his soldiers that he shared the dangers of the cannonade with them. His corps lost in the battle 4,350 out of less than 10,000 fighting men. But it captured 27 Confederate battle flags and as many prisoners as it had men when the fighting ceased. Hancock, himself, was struck in the groin by a bullet, but continued in command until the repulse of the attack. Six months passed before he resumed command. In the battles of the year 1864 Hancock commanded at the Wilderness during the second day's fighting, half of the Union Army; at Spottsylvania he had charge of the successful attack on the "salient"; at Cold Harbor his corps formed the left wing in the unsuccessful assault on the Confederate lines. In August he was

promoted to brig.-general in the Regular Army. His old wound troubling him, he obtained a short leave of absence, expecting to return to his corps. He was, however, detailed to raise a new corps, and later was placed in charge of the "Middle Division." Before he could take the field Richmond had fallen and Lee had surrendered.

After the assassination of Lincoln, Hancock was placed in charge of Washington, and it was under his command that Booth's accomplices were tried and executed. In July 1866 he was appointed major-general in the Regular Army. A little later he was placed in command of the department of the Missouri, and the year following assumed command of the 5th Military Division, comprising Louisiana and Texas. His policy, however, of discountenancing military trials and conciliating the conquered did not meet with approval at Washington, and he was at his own request transferred.

Hancock had all his life been a Democrat. His war record and his personal popularity caused his name to be considered as a candidate for the Presidency, and in 1880 he was nominated for that office by the Democrats, but was defeated by his Republican opponent, Gen. Garfield, by the small popular plurality of 7,000 votes. He died at Governor's island, near New York on Feb. 9, 1886. Hancock was in many respects the ideal soldier of the Northern armies. He was quick, energetic and resourceful, reckless of his own safety, a strict disciplinarian, a painstaking, hard-working officer, a born commander of men. Grant said of him, "Hancock stands the most conspicuous figure of all the general officers who did not exercise a separate command. He commanded a corps longer than any other, and his name was never mentioned as having committed in battle a blunder for which he was responsible."

A biography of him was written by Gen. Francis A. Walker (1894). See also *History of the Second Corps*, by the same author (1886).

(F. H. H.)

HANCOCK, a city of Houghton county, Michigan, in the Upper Peninsula, on Portage lake, opposite Houghton. It is on Federal highway 41, and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Chicago and North Western, the Copper Range and the Mineral Range railways, and by steamers from the Great Lakes through the Portage lake ship canal. The population was 7,527 in 1920, of whom 2,119 were foreign-born white, largely from Finland. It is the seat of the Finnish Evangelical Lutheran Theological seminary, and of the publication house of the denomination. Copper mining and smelting and the manufacture of dairy products are the dominant industries, and the city is growing in popularity as a summer resort and a headquarters for tourists in "Hiawatha Land." The Quincy, Franklin, Hancock, New Baltic and Arcadian mines are in or near the city. Hancock was settled in 1859, incorporated as a village in 1875, and chartered as a city in 1903.

HAND, FERDINAND GOTTHELF (1786-1851), German classical scholar, was born at Plauen in Saxony on Feb. 15, 1786, and died at Jena, where he had held a professorship, on March 14, 1851. His most famous work is his (unfinished) edition of the treatise of Horatius Tursellinus (Orazio Torsellino, 1545-99) on the Latin particles (*Tursellinus, seu de particulis Latinis commentarii*, 1829-45). Like his treatise on Latin style (*Lehrbuch des lateinischen Stils*, 3rd ed. by H. L. Schmitt, 1880), it is too abstruse for the ordinary student. In his *Ästhetik der Tonkunst* (1837-41) he was the first to introduce the subject of musical aesthetics.

The first part of the last-named work has been translated into English by W. E. Lawson (*Aesthetics of Musical Art, or The Beautiful in Music*, 1880), and B. Sears's *Classical Studies* (1849) contains a "History of the Origin and Progress of the Latin Language," abridged from Hand's work on the subject. There is a memoir of his life and work by G. Queck (Jena, 1852).

HAND, the terminal part of the human arm from below the wrist, and consisting of the fingers and the palm. The word is also used of the prehensile termination of the limbs in certain other animals. (See ANATOMY; SKELETON; and such articles as MUSCULAR SYSTEM and NERVOUS SYSTEM.) There are many transferred applications of "hand," as a substantive and in adverbial phrases.

HAND-BALL, a ball game played in a court, the ball being struck against the wall or walls with the hand. Although it is considered a fast game even for men athletically inclined, and one which usually arouses a keen competitive spirit, it can be played in leisurely fashion like tennis or golf by those who seek fun and diversion without extraordinary effort. Played strenuously, it is recommended by some athletic trainers as being better than road running for boxers and wrestlers in preparation for their bouts.

Although the game of hand-ball originated in Ireland a thousand years ago, and is often considered one of the national games of that country, it is now played by more men in America than anywhere else in the world. Hand-ball courts are installed in practically every gymnasium in America, indoors and out, as well as in men's clubs, fraternal organizations and elsewhere. The first scientific hand-ball player was really developed in the early '30s, when William Baggs of Tipperary originated new ways of hitting the ball in curves, low drives and screw tosses. He was followed in Ireland by David Browning. In 1885 John Lawlor of Ireland won the Irish championship. The first international match ever played was the Lawlor-Casey match in 1887 with the prize of \$1,000 for the best of 21 games, 10 in Cork and 11 in the United States. Lawlor won 6 games to 4 in Cork, and Casey, the American champion, won 7 straight in New York, winning the match. Casey, who retained his title against all comers until 1900, when he retired, was spoken of as the "father" of hand-ball in America. McQuade, Alderman Dunne, Judge Dunne, Drew, Cashman, Kelly, Eagan, O'Rourke and Heney were outstanding stars of former days.

Since 1900 hand-ball has developed into two separate games, a one-wall game and a four-wall game, both of which are played by amateurs in singles or doubles. Professional games are unheard of now. The one-wall game (A.A.U. rules) is played in a court 34 ft. long by 20 ft. wide, with front wall 16 ft. high. A "short" line on the floor is 14 ft. from the front wall with a second line 9 ft. further back known as the "service" line. Twenty-one points constitute a game. Preliminary matches consist of two out of three games; semi-final and final matches comprise three out of five games. In serving, the ball must be bounced on the floor within the square formed by the side lines and the short and service lines, and struck on the first bounce. The server must see that the ball will strike the wall and bounce across the short line. Hitting the ceiling, floor or any other part of the room before the front wall, while serving, counts as a lost point. The receiver may strike the ball on the fly or on the first bounce. In singles or doubles, players are entitled to an unobstructed chance at the ball. The ball is 1½ in. in diameter and weighs 2 ounces. There are 37 recognized rules for one-wall hand-ball as adopted at the annual meeting of the A.A.U. on Nov. 20, 1927.

In the four-wall game of hand-ball a standard court 46 ft. long by 22 ft. wide is bounded by four walls 22 ft. high. A serving space enclosed by two parallel lines, the back line and foul-line, drawn across the width is laid out on the floor of the court. The back line, called the "short" line, divides the court equally; the "front" line is 5 ft. in front of it, that is 18 ft. from the front wall. At right angles to these lines and 18 in. from the side walls lines are drawn to form a box where the partner to the man who is serving stands with his back to the side wall while the ball is being served. Should he leave the box before the ball crosses the short line, the referee will declare it a "short" ball. If the server's partner is hit by the ball while in the box, it is considered a dead ball and the ball is out of play. Missing the ball on the first bounce in serving puts the server out, although he has the privilege of several, but not more than three attempts at bouncing the ball before serving. To be in play the ball must hit the front wall and rebound across the short line before striking the floor. While serving the ball the server must stand in the serving space between the two lines. A served ball which does not rebound beyond the short line before touching the floor is termed a short ball, as is also a served ball which rebounds from the front wall and touches the back wall or ceiling before touching the floor, and a served ball which rebounds from the front wall and touches two side walls before touching the floor. If the server steps over the short line while serving, it is termed a "short" ball. If two short balls are served in succession the

server is out. After the ball is served the server's opponents must return the ball to the front wall, before hitting the floor. If the opponents fail to return the ball properly it counts as a tally against the server. If the server or his partner in doubles fails to return the adversary's play properly, the server is out. There are 32 official A.A.U. rules for four-wall hand-ball and this game is usually played indoors exclusively.

The dimensions of the Irish court or alley as given in the playing rules of the Gaelic Athletic Association are: Floor not less than 60 ft. nor more than 63 ft. long, not less than 28 ft. nor more than 30 ft. wide. Height of front wall 30 feet. Height of back wall at least 8 feet.

A.A.U. Champions of the United States: Singles

Year	Champion	Runner-up
1919	Wm. Ranft, Los Angeles.	Joe Lacey, Los Angeles.
1920	Max Gold, Los Angeles.	G. Klawiter, Los Angeles.
1921	Dr. Haedge, St. Paul.	Wm. Sakmann, New York.
1922	A. J. Schinner, Milwaukee.	Wm. Sakmann, New York.
1923	J. Murray, San Francisco.	M. Laswell, Los Angeles.
1924	M. Laswell, Los Angeles.	G. Klawiter, Los Angeles.
1925	M. Laswell, Los Angeles.	Schaufelberger, Detroit.
1926	M. Laswell, Los Angeles.	J. Donovan, San Francisco.
1927	Geo. Nelson, Baltimore.	F. Burke, San Francisco.

Year Champions of Doubles

1919	Ranft and Lacey, Los Angeles.
1920	Klawiter and Retzer, Los Angeles.
1921	Spiegel and Asselin, Detroit.
1922	Gold and Laswell, Los Angeles.
1923	Serenberg and Bathey, Detroit.
1924	McMillan and Donovan, San Francisco.
1925	Dworman and Kammann, Detroit.
1926	Donovan and McMillan, San Francisco.
1927	Dworman and Kammann, Detroit.

See Spalding's *Hand-ball Guide*, No. 114 (1928); Gaelic Athletic Association, *Playing Rules of Football, Hurling, Rounders and Hand-ball*. (J. B. P.)

HANDEDNESS. Why the vast majority of human beings do most things in a right-handed way is a problem which has induced voluminous discussion. Parson, in a recent book, gives some 40 pages of titles of books, pamphlets and articles dealing with various aspects of the problem.

Theories of Handedness.—Theories relative to handedness vary in their treatment of it as an acquired or a native trait. Those who believe it an acquired habit advance many theories to show how it originates. Some relate it to the way a child is held in infancy; others to social training and imitation. Watson, the behaviourist, thinks it a socially conditioned response; forcing the child to eat with the right hand is a potent conditioning factor. The theorists who consider handedness a congenital trait seek to connect it with structural features of the human body. For instance, an appeal has been made in explanation to the unequal visceral distribution in the two halves of the human body and the consequent displacement of the centre of gravity; also to a supposed inequality in a blood supply to the brain, the left cerebral hemisphere, which controls the right half of the body, receiving the greater supply of blood. Many authorities accept the view that right-handedness is due to the functional predominance of the left brain; others cite the dominance of the right eye as explanatory. Ocular dominance and the pre-eminence of the left brain hemisphere must then be explained.

A theory intermediate between explanation of handedness as a habit or dependent upon innate structure, states it originated in primitive warfare, where the stick or sword was wielded by the right hand in order that the left arm and hand might be used for defensive covering of the heart or for holding a shield for this purpose. This racial habit was, according to this theory, transmitted to later generations.

Percentage of Left-handedness.—Acceptance of right-handedness as a native trait is often associated with emphasis on the fact that left-handedness appears to be hereditary in certain family lines. The percentage of left-handedness among normal individuals is estimated to run from 4 to 8%. The percentage is much higher among inmates of institutions for the feeble-minded and the psychopathic.

Left-brainedness.—Right-handed persons are left-brained and left-handed persons right-brained. The motor nerves that innervate the two halves of the body as they descend from the cerebral hemispheres cross over from one side to the other. Some evidence exists that the left hemisphere is more highly organized than the right. Attempts to determine the relative weight of the two hemispheres encounter many sources of error and the results are inconclusive.

Bilaterality.—The problems of handedness should be restated in terms of laterality of function in general. People are right and left footed as well as right and left handed. They also are right-eyed or left-eyed in the sense that in unilateral sighting one eye is preferred to the other. About 70% of right-handed persons are also right-eyed; about 50% of left-handed persons are left-eyed. Discrepancies between preferred hand and eye, described as crossed dextrality or sinistrality, may originate from interference with natural handedness or arise from development of ocular faults. Possibly they may be due to asymmetrical functioning of the nervous system. In any case they appear to be connected with certain psychopathic tendencies.

Bilaterality of Structure and Twinning.—It is probable that we must look to investigations on the biology and physiology of twinning for an ultimate explanation of handedness, since current studies suggest that bilaterality of structure is a form of twinning. In the twinning relation one twin usually gains a physiological ascendancy over the other. Unilaterality of function might arise similarly in man. One would anticipate, however, all degrees of asymmetry between the two body halves. The goal of the biological process would appear to be the development of a bilaterally symmetrical individual.

BIBLIOGRAPHY.—Widely dispersed lists of titles may be found in journals, medical, psychological, physiological and anthropological. For summaries, see B. S. Parson, *Left-Handedness* (1924) and J. E. Downey, "Types of Dextrality and Their Implications," in *Amer. Jour. Psychol.*, vol. xxxviii. (1927). (J. E. D.)

HANDEL, GEORGE FREDERICK (1685-1759), musical composer, was born at Halle, in Lower Saxony, on Feb. 23, 1685. His name was Händel, but, like most 18th century musicians who travelled, he compromised with its pronunciation by foreigners, and when in Italy spelt it Hendel, and in England (where he became naturalized) accepted the version Handel, which is therefore correct for English writers, while Händel remains the correct version in Germany.

LIFE

Early Training.—Handel's father was a barber-surgeon, who disapproved of music and wished George Frederick to become a lawyer. A friend smuggled a clavichord into the attic, and on this instrument, which is inaudible behind a closed door, the little boy practised secretly. Before he was eight his father went to visit a son by a former marriage who was a valet-de-chambre to the duke of Saxe-Weissenfels. The little boy begged in vain to go also, and at last ran after the carriage on foot so far that he had to be taken. He made acquaintance with the court musicians and contrived to practise on the organ when he could be overheard by the duke, who, immediately recognizing his talent, spoke seriously to the father, who had to yield to his arguments.

On returning to Halle Handel became a pupil of Zachau, the cathedral organist, who gave him a thorough training as a composer and as a performer on keyed instruments, the oboe and the violin. Six very good trios for two oboes and bass, which Handel wrote in his 11th year, are extant; and when he himself was shown them by an English admirer who had discovered them, he was much amused and remarked, "I wrote like the devil in those days, and chiefly for the oboe, which was my favourite instrument." These trios were mere parerga beside the study and composition of vocal music, and he had to show Zachau a motet every week. By the time he was 12 Zachau thought he could teach him no more, and accordingly the boy was sent to Berlin, where he made a great impression at the court.

His father, however, thought fit to decline the proposal of the elector of Brandenburg, afterwards King Frederick I. of Prussia, to send the boy to Italy in order afterwards to attach him to the

court at Berlin. German court musicians, as late as the time of Mozart, had hardly enough freedom to satisfy a man of independent character, and the elder Handel had not yet given up hope of his son becoming a lawyer. Young Handel, therefore, returned to Halle and resumed his work with Zachau. In 1697 his father died, but the boy with great filial piety, finished the ordinary course of his education, both general and musical, and entered the university of Halle in 1702 as a law student. But in that year he succeeded to the post of organist at the cathedral, and after his "probation" year in that capacity he departed to Hamburg, where the only German opera worthy of the name was flourishing under the direction of its founder, Reinhold Keiser.

Friendship with Matheson.—Here he became friends with Matheson, a prolific composer and writer on music. On one occasion they set out together to go to Lübeck, where a successor was to be appointed to the post left vacant by the great organist Buxtehude, who was retiring at the age of 90. Handel and Matheson made much music on this occasion, but did not compete, because they found that the successful candidate was required to marry the retiring organist's daughter. Another adventure might have had even more serious consequences. At a performance of Matheson's opera *Cleopatra* at Hamburg, Handel refused to give up the conductor's seat to the composer when the latter returned to his usual post at the harpsichord after singing the part of Antony on the stage. The dispute led to a duel outside the theatre, and, but for a large button on Handel's coat which intercepted Matheson's sword, there would have been no *Messiah* or *Israel in Egypt*. But the young men remained friends, and Matheson's writings are full of the most valuable facts for Handel's biography. He relates in his *Ehrenpforte* that his friend at that time used to compose "interminable cantatas" of no great merit; but of these no traces now remain, unless we assume that a Passion according to St. John, the manuscript of which is in the royal library at Berlin, is among the works alluded to. But its authenticity, while strongly upheld by Chrysander, has since been as strongly assailed on internal evidence.

On Jan. 8, 1705, Handel's first opera, *Almira*, was performed at Hamburg with great success, and was followed a few weeks later by another work, entitled *Nero*. *Nero* is lost, but *Almira*, with its mixture of Italian and German language and form, is extant. It contains many themes used by Handel in well-known later works; but the current statement that the famous aria in *Rinaldo*, "Lascia ch'io pianga," comes from a saraband in *Almira*, is based upon nothing more definite than the common form of saraband-rhythm.

Three Years in Italy.—In 1706 Handel left Hamburg for Italy, where he remained for three years, rapidly acquiring the smooth Italian vocal style which thereafter always characterized his work. He had before this refused offers from noble patrons to send him there, but had now saved enough money not only to support his mother at home, but to travel as his own master. He divided his time in Italy between Florence, Rome, Naples, and Venice; and many anecdotes are preserved of his meetings with Corelli, Lotti, Alessandro Scarlatti, the founder of the Neapolitan school, or rather of the classical language of music as understood by Handel himself, and Alessandro's unacademic son Domenico, whose wonderful harpsichord technique still furnishes problems for the modern pianoforte virtuoso. Handel soon became famous as *Il Sassone* ("the Saxon"), and it is said that Domenico on first hearing him play incognito exclaimed, "It is either the devil or the Saxon!"

There is also a story of Corelli's coming to grief over a passage in Handel's overture to *Il Trionfo del tempo*, in which the violins went up to A in altissimo. Handel impatiently snatched away the violin to show Corelli how the passage ought to be played, and Corelli, who had never written or played beyond the third position in his life (this passage being in the seventh), said gently, "My dear Saxon, this music is in the French style, which I do not understand." The story becomes more interesting in view of the fact that Handel's later treatment of the violin is hardly less restrained than Corelli's, though he often wrote for the greatest players of the day.

In Italy he produced two operas, *Rodrigo* and *Agrippina*, the latter a very important work, of which the splendid overture was remodelled 44 years afterwards as that of his last original oratorio, *Jephtha*. He also produced two oratorios, *La Resurrezione*, and *Il Trionfo del tempo*. The latter, 46 years afterwards, formed the basis of his last work, *The Triumph of Time and Truth*, which contains no original matter. All Handel's early works contain material that he used often with very little alteration later on, and, though the famous "Lascia ch'io pianga" does not occur in *Almira*, it occurs note for note in *Agrippina* and the two Italian oratorios. On the other hand the cantata *Acis, Galatea e Polifemo* has nothing in common with *Acis and Galatea*.

Besides these larger works there are several choral and solo cantatas of which the earliest, such as the great *Dixit Dominus*, show in their extravagant vocal difficulty how radical was the change which Handel's Italian experience so rapidly effected in his methods. Handel's success in Italy established his fame and led to his receiving at Venice in 1709 the offer of the post of Kapellmeister to the elector of Hanover, transmitted to him by Baron Kielmansegge, his patron and staunch friend of later years.

Career in England.—Handel at the time contemplated a visit to England, and he accepted this offer on condition of leave of absence being granted to him for that purpose. To England accordingly Handel journeyed after a short stay at Hanover, arriving in London towards the close of 1710. He came as a composer of Italian opera, and earned his first success at the Haymarket with *Rinaldo*, composed, to the consternation of the hurried librettist, in a fortnight, and first performed on Feb. 24, 1711. In this opera the aria "Lascia ch'io pianga" found its final home. The work was produced with the utmost magnificence, and Addison's delightful reviews in the *Spectator* poked fun at it from an unmusical point of view in a way that would have pleased Gluck 50 years afterwards. The success was so great, especially for Walsh the publisher, that Handel proposed that Walsh should compose the next opera and that he (Handel) should publish it! He returned to Hanover at the close of the opera season and composed a good deal of vocal chamber music for the princess Caroline, the step-daughter of the elector, besides the instrumental works known to us as the "oboe concertos."

In 1712 Handel returned to London and spent a year with Andrews, a rich musical amateur, in Barn Elms, Surrey. Three more years were spent in Burlington, in the neighbourhood of London. He evidently was but little inclined to return to Hanover, in spite of his duties to the court there. Two Italian operas and the Utrecht Te Deum, written by the command of Queen Anne, are the principal works of this period. It was awkward for the composer when his deserted master came to London in 1714 as George I. of England. For some time Handel did not venture to appear at court, and it was only at the intercession of Baron Kielmansegge that his pardon was obtained. By his advice Handel wrote the Water Music which was performed at a royal water party on the Thames, and it so pleased the king that he at once received the composer into his good graces and granted him a salary of £400 a year.

Later Handel became music master to the little princesses and was given an additional £200 by the princess Caroline. In 1716 he followed the king to Germany, where he wrote a second German Passion to the popular poem of Brockes, a text which, divested of its worst features, forms the basis of several of the arias in Bach's Passion according to St. John. This was Handel's last work to a German text. A copy much more accurate than Handel's autograph, exists in Bach's handwriting.

Composer and Impresario.—On his return to England he entered the service of the duke of Chandos as conductor of his concerts, receiving a thousand pounds for his first oratorio *Esther*. The music which Handel wrote for performance at Cannons, the duke of Chandos's residence at Edgware, is comprised in the first version of *Esther*, *Acis and Galatea*, and the twelve Chandos Anthems, which are compositions approximately in the same form as Bach's church cantatas but without any systematic use of chorale tunes. The fashionable Londoner would travel nine miles in those days to the little chapel of Whitchurch to hear Handel's

music; of the magnificent scene of these visits all that now remains is the church, which is the parish church of Edgware.

In 1720 Handel appeared again in a public capacity as impresario of the Italian opera at the Haymarket theatre, which he managed for the institution called the Royal Academy of Music. Senesino, a famous singer, to engage whom Handel especially journeyed to Dresden, was the mainstay of the enterprise, which opened with a highly successful performance of Handel's opera *Radamisto*. To this time belongs the famous rivalry between Handel and Buononcini, a melodious Italian composer whom many thought to be the greater of the two. The controversy has been perpetuated in John Byrom's well-known lines:

Some say, compared to Buononcini
That Mynheer Handel's but a ninny;
Others aver that he to Handel
Is scarcely fit to hold a candle.
Strange all this difference should be
Twixt tweedle-dum and tweedle-dee.

It must be remembered that at this time Handel had not yet asserted his greatness as a choral writer. The fashionable ideas of music and musicianship were based entirely upon success in Italian opera, and the contest between the rival composers was waged on the basis of works which have fallen into almost as complete oblivion in Handel's case as in Buononcini's. Apart from scholarly revivals, none of Handel's 41 Italian operas survives, except in some few detached arias out of each opera; arias which reveal their essential qualities far better in isolation than when performed in groups of between 20 and 30 on the stage, as interruptions to the action of a classical drama which was nothing but an interruption to them. But even under these conditions Handel's inexhaustible inventive power proved decisive; as was shown when he wrote the third act of an opera *Muzio Scevola*, of which Buononcini and Ariosti (Chrysander says Mattei) wrote the other two. Buononcini soon got into discredit by failing to defend himself against the charge of producing as a prize-madrigal of his own a composition which proved to be by Lotti. As a consequence Buononcini left London, and Handel for the next ten years was without a rival in his ventures as an operatic composer.

From Opera to Oratorio.—He was not, however, without a rival as an impresario; and the hostile competition of a rival company which obtained the services of the great Farinelli and also induced Senesino to desert him led to his bankruptcy in 1737, and to an attack of paralysis caused by anxiety and overwork. The rival company, it may be added, also had to be dissolved from want of support. Handel's artistic conscience was that of an opportunist, or he would never have continued till 1741 to work in a field that gave so little scope for his genius. But operas were the only music that was known to pay, and at all events he could supply better operas more quickly and easily than any other living composer. And this he naturally continued to do so long as it seemed the best way to keep up his reputation. But his opportunism did not include a readiness to stand any nonsense; and when the prima-donna Cuzzoni tried to give herself other airs than he had written for her, he held her at arm's length out of a window until she capitulated.

Already before his last opera, *Deidamia*, produced in 1741, Handel had been making a growing impression with his oratorios. In these, freed from the restrictions of the stage, he was able to give scope to his genius for choral writing, and so to develop, or rather revive, that art of chorus singing which is the normal outlet for English musical talent. In 1726 Handel had become a naturalized Englishman, and in 1733 he began his public career as a composer of English texts by producing the second and larger version of *Esther* at the *King's Theatre*. This was followed early in the same year by *Deborah*, in which the share of the chorus is much greater. In July he produced *Athalie* at Oxford, the first work in which his eight-part double choruses appear. The share of the chorus increases in *Saul* (1738); and *Israel in Egypt* (also 1738) is practically entirely a choral work, the solo movements being few and, in spite of their fame, perfunctory. The public, who still considered Italian opera the highest form of musical art, not unnaturally obliged Handel at subsequent per-

formances of this gigantic work to insert more solos.

The Messiah was produced at Dublin on April 13, 1742. *Samson* (which Handel preferred to *The Messiah*) appeared at Covent Garden on March 2, 1744; *Belshazzar* at the King's theatre, March 27, 1745; the *Occasional Oratorio* (chiefly a compilation of the earlier oratorios, but with a few important new numbers), on Feb. 14, 1746, at Covent Garden, where all his later oratorios were produced; *Judas Maccabaeus* on April 1, 1747; *Joshua* on March 9, 1748; *Alexander Balus* on March 23, 1748; *Solomon* on March 17, 1749; *Susanna*, spring of 1749; *Theodora*, a great favourite of Handel's, who was much disappointed by its cold reception, on March 16, 1750; *Jephtha* (strictly speaking, his last work) on Feb. 26, 1752, and *The Triumph of Time and Truth* (transcribed from *Il Trionfo del tempo* with the addition of many later favourite numbers), in 1757. Other important works, indistinguishable in artistic form from oratorios but on secular subjects, are *Alexander's Feast*, 1736; *Ode for St. Cecilia's Day* (words by Dryden); *L'Allegro, il penseroso ed il moderato* (Milton, with a third part by Jennens), 1740; *Semele*, 1744; *Hercules*, 1745; and *The Choice of Hercules*, 1751.

Last Years.—By degrees the enmity against him died away, though he had many troubles. In 1745 he had again become bankrupt; for, although he had no rival as a composer of choral music, it was possible for his enemies to give balls and banquets on the nights of his oratorio performances. As with his first bankruptcy, so in his later years, he was scrupulously honourable in discharging his debts, and, like Scott, he continued to work hard to the end of his life. Unlike Scott, he not only completely recovered his financial position (by the year 1750) but he must have made a good deal of money, for he then presented an organ to the Foundling Hospital, and opened it with a performance of *The Messiah* on May 15.

In 1751 his sight began to trouble him; and the autograph of *Jephtha*, published in facsimile by the *Händelgesellschaft*, shows pathetic traces of this in his handwriting, and so greatly reveals his methods of composition, all the accompaniments, recitatives, and less essential portions of the work being evidently filled in long after the rest. By a dramatic coincidence Handel's blindness interrupted him during the writing of the chorus, "How dark, oh Lord, are Thy decrees, . . . all our joys to sorrow turning . . . as the night succeeds the day." He underwent unsuccessful operations, one of them by the same surgeon who had operated on Bach's eyes. He was able to see at intervals during his last years, but his sight practically never returned after May 1752.

He continued nevertheless superintending performances of his works and writing new arias for them, or inserting revised old ones, and he attended a performance of *The Messiah* a week before his death, which took place, according to the *Public Advertiser* of April 16, not on Good Friday, April 13, according to his own pious wish and according to common report, but on April 14, 1759. He was buried in Westminster Abbey; and his monument is by L. F. Roubilliac, the same sculptor who modelled the marble statue erected in 1739 in Vauxhall gardens, where his works had been frequently performed.

Handel was a man of high character and intelligence, and his interest was not confined to his own art exclusively. He liked the society of politicians and literary men, and he was also a collector of pictures and articles of *vertu*. His power of work was enormous, so that the *Händelgesellschaft's* edition of his complete works fills 100 volumes, forming a total bulk almost equal to the works of Bach and Beethoven together. (F. Hv.; D. F. T.)

MUSIC

Handelian Opera.—No one has more successfully popularized the greatest artistic ideals than Handel; no artist is more disconcerting to critics who expect to follow a great man's mental development easily. Not even Wagner effected a greater transformation in the possibilities of dramatic music than Handel effected in oratorio, yet we have seen that Handel was the very opposite of a reformer. Indeed he hardly took the pains to ascertain what an art-form was, so long as something externally

like it would convey his idea. But he never failed to convey his idea, and, if the hybrid forms in which he conveyed it had no historic influence and no typical character, they were none the less fit for each case. The same aptness and the same absence of method are conspicuous in his style.

The popular idea that Handel's style is easily recognizable comes from the fact that he overshadows all his predecessors and contemporaries, except Bach, and so makes us regard typical 18th century Italian and English style as Handelian, instead of regarding Handel's style as typical Italian 18th century. Nothing in music requires more minute expert knowledge than the sifting of the real peculiarities of Handel's style from the mass of contemporary formulae which in his inspired pages he absorbed, and which in his uninspired pages absorbed him.

His easy mastery was acquired, like Mozart's, in childhood. The sonatas for two oboes and bass which he wrote in his 11th year are, except in their diffuseness and an occasional slip in grammar, indistinguishable from his later works, and they show a boyish inventiveness worthy of Mozart's work at the same age. Such early choral works, as the *Dixit Dominus* (1707), show the ill-regulated power of his choral writing before he assimilated Italian influences. Its practical difficulties are at least as great as Bach's though they are not as necessary; but the grandeur of the scheme and nobility of thought are already those for which Handel so often in later years found the simplest adequate means of expression that music has ever attained. His eminently practical genius soon formed his vocal style, and long before the period of his great oratorios such works as *The Birthday Ode* for Queen Anne (1713) and the *Utrecht Te Deum* show not a trace of extravagance.

Operatic Methods.—The only drawback to his practical genius was that it led him to bury perhaps half of his finest melodies, and nearly all the secular features of interest in his treatment of instruments and of the aria forms, in that limbo of vanity, the 18th century Italian opera. The allegation is untrue that his operas are no better than those of his contemporaries; but it is certainly true that he never stirred a finger to improve the condition of dramatic musical art. He was notoriously masterful with singers; and was not bound by the operatic conventions of the time. In *Teseo* he not only wrote an opera in five acts when custom prescribed three, but also broke a much more rational rule in arranging that each character should have two arias in succession.

He also showed a feeling for expression and style which led him to write arias of new kinds. But he never made any innovation which had the slightest bearing upon the stage-craft of opera, for he never concerned himself with any artistic question beyond the matter in hand; and the matter in hand was neither to create dramatic music nor to make the story intelligible, but simply to provide a concert of between some 20 and 30 Italian arias and duets, wherein singers could display their abilities and spectators find distraction from the monotony of so large a dose of the aria form (which was then the only opportunity for solo vocal music) in gorgeous costumes and scenery.

The Transition to Oratorio.—When the question arose how such musical entertainments could be managed in Lent without protests from the bishop of London, Handelian oratorio came into being as a matter of course. But though Handel was an opportunist he was not shallow. His artistic sense seized upon the natural possibilities which arose as soon as the music was transferred from the stage to the concert platform; and his first English oratorio, *Esther* (1720), beautifully shows the transition.

The subject is as nearly secular as any that can be extracted from the Bible, and the treatment was based on Racine's *Esther*, which was much discussed at the time. Handel's oratorio was reproduced in an enlarged version in 1732 at the King's theatre; the princess royal wished for scenery and action, but the bishop of London protested. And the choruses, of which in the first version there are already no fewer than ten, are on the one hand operatic and unecclesiastical in expression, until the last, where polyphonic work on a large scale first appears; but on the other hand they are all much too long to be sung by heart, as is neces-

sary on the stage. In fact, the turning-point in Handel's development is the emancipation of the chorus from theatrical limitations. This had as great an effect upon his few but important secular English works as upon his other oratorios. *Acis and Galatea*, *Semele*, and *Hercules* are in fact secular oratorios; the choral music in them is pagan, but it is large, independent, and polyphonic.

Handel's scheme of oratorio is, then, operatic in its origin and has no historic connection with the German Passion music of his time; and nothing is more significant than that the chorus should have so readily assumed its proper place in a scheme which the public at first certainly regarded as a sort of Lenten biblical opera. And, as the chorus gains its musical freedom by the disappearance of theatrical necessities, it becomes the more powerful as a means of dramatic expression (as opposed to dramatic action).

Already in *Athalia* the "Hallelujah" chorus at the end of the first act is a marvel of dramatic truth. It is sung by Israelites almost in despair beneath usurping tyranny; and accordingly it is a severe double fugue in a minor key, expressive of devout courage at a moment of depression. On purely musical grounds it is no less powerful in throwing into relief the ecstatic solemnity of the psalm with which the second act opens. Now this sombre "Hallelujah" chorus conveniently illustrates the real originality and creative power of Handel's art. It was not originally written for its situation in *Athalia*, but it was chosen for it. It was originally the last chorus of the second version of the anthem, "As pants the Hart," from the autograph of which it is missing because Handel cut out the last pages in order to insert them into the manuscript of *Athalia*. The inspiration in *Athalia* thus lies not in the creation of the chorus itself, but in the choice of it.

In choral music Handel made no more innovation than he made in arias. His sense of fitness in expression was of little use to him in opera, because opera could not become dramatic until musical forms broke with architectural and decorative limitations (see GLUCK; MUSIC; SONATA-FORMS; and INSTRUMENTATION). But in oratorio there was no necessity for reforming any art-forms. The ordinary choral resources of the time had perfect expressive possibilities where there were no actors and actions to keep waiting. Moreover, when ordinary decorum dictated an attitude of reverent attention towards the subject of the oratorio, then the man of genius could find the true scope for his dramatic sense and base immortal music thereon.

Musical Borrowings.—Handel must be estimated in terms of Shakespearean criticism. Originality, in music as in other arts, lies in the whole, and in a sense of the true meaning of every part. When Handel wrote a normal double fugue in a minor key on the word "Hallelujah" he showed that he enjoyed the vigour and dignity of good 18th century double fugues. In putting it at the end of a melancholy psalm he showed his sense of the value of the minor mode. When he put it in its situation in *Athalia* he shed upon it the light of a truly conceived dramatic situation. Handel himself did not more often transfer old work to new contexts than the first and greatest reformer of dramatic music who thrust Handelian opera into limbo (see GLUCK). Such procedures are interesting enough in any case; but musical criticism is unused to the cases where the borrowed material is not the composer's own; desperate efforts have been made to vindicate Handel or explain away the composers who were to Handel what Holinshed's Chronicles, Sidney's Arcadia, and North's Plutarch were to Shakespeare.

On such matters heat is unaccompanied by light. No apology for Handel can plausibly maintain that his enormous physical industry was not compensated for by the Johnsonian indolence of a well-stocked mind. One writer (P. Robinson, *Handel and his Orbit*) tries to explain away Handel's Holinsheds and Plutarchs by pointing out that Urio and Erba, etc., are place-names around the Italian lakes which Handel visited. You cannot explain away Palestrina and half the Italian masters of painting by pointing out that their names are place-names; nor can you thus explain why Handel, who cares so little for art-forms, should faithfully imitate the minutest features of a style 50 years earlier than his

own, or why his manuscript of the archaic Erba Magnificat should break off as a copyist breaks off, from the top of the page downwards. Besides, why explain away these Italian masters (whose existence as persons is attested by other evidence) when Handel borrowed a chorus in *Esther* from Graun?

This disposes, on the other hand, of attacks made on Handel's morality in plagiarising from sources that could never be traced in his lifetime. Within four years of Handel's death the child Mozart dedicated a set of sonatas to Queen Charlotte with the assurance that, inspired by her Majesty's protection "je deviendrai immortel comme Händel et Hasse"; and if he had substituted Graun, his patroness and his public would have missed no point but the alliteration. The only plausible reason why Handel did not plagiarise from Bach is that he would have thought any chorus of Bach quite impracticable in England. With the old Erba Magnificat the puzzle is that Handel should have thought such leaden vocal writing worth borrowing for *Israel in Egypt*. He could not add four chords, with the words "my fathers' God" without producing a vocal colour that aggravates rather than relieves the surrounding muddiness.

The most probable explanation is that Handel, who never thought of writing an original eight-part fugue, seriously imagined like an examiner for a university musical doctorate, that eight-part fugues were objects of veneration, and that the British public would be the better for hearing some old Italian masterpieces in this form. At all events he made no attempt to improve the Erba fugues, or even to assign them to texts that gave a tolerable declamation. A fugue on *Sicut erat in principio et nunc et semper* has to be sung to the words "THE earth swal . . . lowed them."

Plagiarism or Transmutation?—Handel's plagiarisms begin to be interesting when we turn from these wholesale pilferings to his real transmutations of foreign elements. For English readers Sedley Taylor's volume of analysed illustrations (*The Indebtedness of Handel to the works of other Composers*, Cambridge 1906) is indispensable for a true understanding of the case. Its appearance gave rise to renewals of controversy which proved how dangerous it would have been to Handel if the matter had been raised in his lifetime. His rival Buononcini was finally discredited by the discovery that he had sent in as his own work for a prize competition a madrigal by Lotti. What, say the moralists, was one madrigal against Handel's wholesale thefts? This query overlooks the distinction between a single prize composition, which is nothing if not wholly original, and a four-hours' entertainment which was so seldom entirely new that it was specially advertised to be so when that statement was permissible.

Hardly any two performances of Handel's oratorios took place, during his lifetime, without the addition and substitution of many favourite airs from other works. Later on, in the time of Mozart, performances of operas (which had become much tighter unities than Handelian oratorios) were often adorned with inserted arias by other composers; Mozart's own contributions to other men's operas fill two stout volumes. Music was in the same condition as architecture; and Handel was as indebted to other composers as Wren was to Palladian architects, and as Mozart was (especially in his Requiem) to Handel. And no fear that discovery might discredit him seems to have entered into Handel's mind, for he left his whole musical library to his copyist, and it was from this library that the sources of his work were discovered.

The true plagiarist is the man who does not know the meaning of the ideas he copies, and the true creator is he in whose hands they remain or become true ideas. The theme "He led them forth like sheep" in the chorus "But as for his people" is one of the most beautiful in Handel's works, and we may be shocked by the bare statement that it comes from a serenata by Stradella. But, to any one who knew Stradella's treatment of it first, Handel's would come as a greater revelation than if he had never heard the theme before. Stradella makes nothing more of it than an agreeably frivolous tune which lends itself to comedic purposes by repetition, throughout eight pages of patchy aria and ritornello, at an ever-increasing pace. What Handel sees in it is what he makes of it, one of the most solemn and poetic things

in music.

Again, how shocking that the famous opening of the "Hailstone chorus" comes from the patchy and facetious overture to this same serenata, with which it is identical for ten bars all in the tonic chord representing, according to Stradella, someone knocking at a door. And how yet more shocking that the chorus "He spake the word, and there came all manner of flies" contains no idea of Handel's own; at least, none except the realistic swarming violin-passages, the general structure, and the vocal colouring; whereas the rhythmic and melodic figures of the voice parts come from an equally patchy *sinfonia concertata* in Stradella's work.

The effects of Handel's original inspiration upon foreign material are really the best indication of the range of his style. The comic intention of Stradella's doorknocking overture becomes Handel's inspiration in the "Hailstone chorus." In the theme of "He led them forth like sheep" what Stradella thought frivolous Handel makes sublime.

The converse process is equally instructive. In the short carillon choruses in *Saul*, where the Israelitish women welcome David after his victory over Goliath, Handel uses a delightful instrumental tune which stands at the beginning of a *Te Deum* by Urio, from which he drew extensively in *Saul*, *L'Allegro*, the Dettingen *Te Deum*, and other works. Urio's idea is first to make a jubilant and melodious noise from the lower register of the strings, and then to bring out a flourish of high trumpets as a contrast. The tune could not bear and does not receive any further development, beyond statement and counterstatement. It has none of the solemnity of church music, and its value as a contrast to the flourish of trumpets depends, not upon itself, but upon its position in the orchestra. Handel did not see in it a fine opening for a *Te Deum*, but he saw in it a perfect type of popular jubilation, and, taking it at its face value as a popular tune he raised it to a high dramatic level. So he uses it as an instrumental interlude accompanied with a jingle of carillons, while the daughters of Israel sing to a square-cut tune those praises of David which aroused the jealousy of Saul.

But now turn to the opening of the Dettingen *Te Deum* and see realized the other side of Urio's idea, the contrast between a jubilant noise in the lowest part of the scale and the blaze of trumpets at an extreme height. In the fourth bar of the Dettingen *Te Deum* we find the same florid trumpet figures as we find in the fifth bar of Urio's, but at the first moment they are on oboes. The first four bars beat a tattoo on the tonic and dominant, with the whole orchestra, including trumpets and drums, in the lowest possible position, with all the drastic power of Handel's genius. Then the oboes appear with Urio's trumpet flourishes; the momentary contrast is not less brilliant than Urio's; but when the oboes are immediately followed by the same figures on the trumpets themselves the contrast gains gradation and climax. Moreover, these flourishes are more melodious than the sledge-hammer opening, whereas in Urio's scheme they were mere conventionalities coming after a good melody. Lastly, Handel's primitive opening rhythmic figures inevitably underlie every subsequent inner part and bass that occurs at every half close and full close throughout the movement, especially where the trumpets are used. And thus every detail of his scheme is rendered alive with a rhythmic significance like that of the themes of Beethoven's second period, whereby he obtains the liveliness of polyphony without fussiness.

Greatness of the Oratorios.—No other great composer has ever so overcrowded his life with occasional and mechanical work as Handel, and in no other artist are the qualities that make the difference between inspired and uninspired pages more elusive. The libretti of his oratorios are full of absurdities, except when they are derived in every detail from Scripture, as in *The Messiah* and *Israel in Egypt*, or from the classics of English literature, as in *Samson* and *L'Allegro*. The absurdities, and the way in which all Handel's works exist by taking in each other's washing, only serve to strengthen the conviction of sound musicians that Handel's originality and greatness consist in his grasp of the works as wholes. They would not matter but for the fact that in English oratorio Handel created a true art-form on the

largest possible scale.

Though drama, in the proper and Aristotelian sense of action, was inherently beyond the terms of Handel's art, the two main qualities of dramatic language, viz., rhetoric and characterization, are at their highest power in all his music, and are, in spite of all that an obscurantist piety has done to conceal them, a main source of his popularity. The 18th century love-affairs of the Israelite warriors and their Israelite maidens cease to resemble the Loves of the Triangles when Handel's music begins to discriminate. It cannot always save the situation, unless we are prepared (as the bishop of London in 1740 was not) to be amused at the contrast between the passionate Elder and the crafty Elder in their trio with the chaste Susannah. But it leaves no part of the work altogether lifeless, even where the music is most perfunctory. Neither the chorus nor the solo parts admit any lay-figures. The heathen are so delightfully pagan that Handel has often been praised for his sympathy with them; but it is a feebly man-about-townish view that thinks his orthodox Jews and Christians less true to their ideals and to life. Their music is the work of the man who hoped to die on Good Friday that he might rise with his Christ on Easter Day.

The power of Handel's English declamation is famous and might with advantage be used as a touchstone for the originality of his setting of words. For instance, the theme of "For unto us a child is born" puts an awkward strain on the word "For"; whereas the next theme, "And the government shall be upon his shoulder," is magnificently suggestive of the action symbolical of assuming the load of government. The rest of the chorus "Wonderful Counsellor," etc., obviously goes straight to the point. Now the first two themes come from an earlier Italian duet, of which the first words are *No, da voi non più fidarmi*, so that the word "For" replaces the exclamation "No." The other theme was meant to scold blind Love for its lying cajoleries, the word "shoulder" coinciding with *lusinghe . . . re*. Handel, seeing in this theme the possibility of a majestic interpretation, put up with a slight inconvenience in the opening theme for the sake of the spacious general structure of the whole movement which was easily expanded to include the new material of "Wonderful Counsellor."

It can hardly be doubted that the melody of "He shall feed his flock like a shepherd" was originally composed to some text, now lost, which gave the awkward expansion and fall of the word "shepherd" (scarcely better on the word "weary") a meaning as convincing as the famous "sheds delicious death" in *Acis and Galatea*.

The Additional Accompaniments Question.—There never has been a time when Handel has been overrated, except in so far as other composers have been neglected. But this favourite musician of the non-musician suffers grievously from pious misinterpretation and the popular admiration of the wrong externals. Chrysander spoke true and winged words about the burial of Handel's art beneath "mammoth" Handel Festivals at the Crystal Palace; but greater damage has been done to performances on a normal scale by the use of "additional accompaniments" in the style of a later symphonic art, started most unfortunately by Mozart (whose share in the work has been corrupted in its turn) and continued throughout the 19th century in progressive stages of insensibility until Handel's style has become as unrecognizable as Nash's Regent street.

But while it is obvious that in *The Messiah* Mozart's orchestral colouring is for the most part an intrusion, the desire for purity of style overreaches itself when it leads to a condemnation of Mozart's work in *Acis and Galatea* and the smaller *Ode to St. Cecilia's Day*. (The accompaniments to *Alexander's Feast*, published in Mozart's name, are obviously by no artist of even ordinary competence.) Handel's secular style is by no means remote from Mozart's, and he leaves so much to the discretion of the performer that it is no indiscretion to allow Mozart to convert Handel's often very perfunctory sketch into a perfect Mozart-Handel work of art.

The result is at all events less heterogeneous than the cadenzas inserted by recent *Musikgelehrte* who out of the fullness of

research achieve a style which no real composer at any period would receive without derision.

For the rest, when the worst has been said concerning either his own weaknesses or the misdeeds of his editors, musicians will never cease to love and revere Handel as one of the greatest of composers, whose inspired work is a marvel of architectonic power, perfect sense of style, and the power to rise to the most sublime heights by the simplest means.

Works and Editions.—His important works have all been mentioned above with their dates, and a separate detailed list is unnecessary. He was an extremely rapid worker, and his later works are dated almost day by day as they proceed. From this we learn that *The Messiah* was sketched and scored within 21 days, and that *Jephtha*, with an interruption of nearly four months besides several other delays caused by Handel's failing sight, was begun and finished within seven months, representing hardly five weeks' actual writing.

Handel's extant works may be roughly summarized from the edition of the *Händelgesellschaft* as 41 Italian operas, 2 Italian oratorios, 2 German Passions, 18 English oratorios, 4 English secular oratorios, 4 English secular cantatas, and a few other small works, English and Italian, of the type of oratorio or incidental dramatic music; 3 Latin settings of the *Te Deum*; the (English) *Dettingen Te Deum* and *Utrecht Te Deum* and *Jubilate*; 4 coronation anthems; 3 volumes of English anthems (*Chandos Anthems*); 1 volume of Latin church music; 3 volumes of Italian vocal chamber-music; 1 volume of clavier works; 37 instrumental duets and trios (sonatas), and 4 volumes of orchestral music and organ concertos (about 40 works). Precise figures are impossible as there is no means of drawing the line between *pasticcios* and original works. The instrumental pieces especially are used again and again as overtures to operas and oratorios and anthems.

The complete edition of the German *Händelgesellschaft* suffers from being the work of one man who would not recognize that his musicianship was unequal to the nature of the task, and that the quantity of the task was beyond any single man's power. The best editions in vocal score are undoubtedly those published by Novello that are not based on "additional accompaniments." None is absolutely trustworthy, and those of the editor of the German *Händelgesellschaft* are sad proofs of the uselessness of library-scholarship without practical musicianship. Yet Chrysander's services in the restoration of Handel are beyond praise. His discovery of authentic trombone parts in *Israel in Egypt* is one among many valuable contributions by him to musical history and aesthetics.

(D. F. T.)

BIBLIOGRAPHY.—Collected *Works of Handel* printed for the Handel Society, London (1844-58); J. Mainwaring, *Memoirs of the late G. F. Handel* (1760); J. Hawkins, *General History of the Science and Practice of Music* (1776); C. Burney, *Account of the Musical Performances at Westminster, etc.* (1785); F. Chrysander, *G. H. HANDEL-MAZZETTI, ENRICA, BARONESS VON (1871-), Austrian author, was born at Vienna on Jan. 10, 1871. She is the author of many historical novels, and has shown a peculiar aptitude for depicting the manners, customs and modes of thought of earlier times. The majority of her books are imbued with the spirit of Roman Catholicism, a result of her religious education at Saint Pölken, and are, in fact, propagandist stories.

Her most important works are: *Meinrad Helmpersgers denkwürdiges Jahr* (1900); *Jesse und Marie* (1906); *Die Arme Margaret* (1910); *Stefana Schwertner* (1913, 3 vols.); *Der deutsche Held* (1920); *Das Rosenwunder* (1925).

See E. Korrodi, *Enrica von Handel-Mazzetti* (1909); Brecka, *Die Handel-Mazzetti* (1923); Speckmann, *Quellen und Komposition der Trilogie "Stefana Schwertner"* (1924).

HANDEL FESTIVAL, one of the most famous and long-established of musical festivals, held periodically at the Crystal

Palace, London, and designed originally to celebrate the centenary of Handel's death. A preliminary performance took place at the Crystal Palace in 1857. This was followed by the centenary festival of 1859, and thenceforward the festivals have been continued more or less regularly triennially, the successive conductors having been Costa (1857-80), Manns (1883-1900), Cowen (1903-23) and Wood (1926). The programmes are devoted usually to complete oratorios on two days, the *Messiah* being invariably one of them, and to selections on the other.

HANDBASTING, primarily the O.E. synonym for *betrothal* (*q.v.*), and later a form of temporary marriage at one time common in Scotland, the only ceremony being the verbal pledge of the couple while holding hands (A.S. *handfoestnung* pledging one's hand). The pair thus handfasted were, in accordance with Scotch law, entitled to live together for a year and a day. If then they so wished, the temporary marriage could be made permanent; if not, they could go their several ways without reproach, the child, if any, being supported by the party who objected to further cohabitation.

HANDICAP, a disadvantageous condition imposed upon the superior competitor in sports and games, or an advantage allowed the inferior in order to equalize the chances of both (from the expression *hand in cap*, referring to drawing lots). The character of the handicap depends upon the nature of the sport. Thus in horse-racing the better horse must carry the heavier weight. In foot races the inferior runners are allowed to start at certain distances in advance of the best (or "scratch") man, according to their previous records. In distance competitions (weights, fly-casting, jumping, etc.) the inferior contestants add certain distances to their scores. In time contests (yachting, canoe-racing, etc.) the weaker or smaller competitors subtract certain periods of time from that actually made, reckoned by the mile. In stroke contests (e.g., golf) a certain number of strokes are subtracted from or added to the scores, according to the strength of the players. In chess and draughts the stronger competitor may play without one or more pieces. In court games (tennis, lawn-tennis, rackets, etc.) and in billiards, certain points, or percentage of points, sometimes called *bisques*, are accorded the weaker players.

HANDICRAFTS, manual skill, or skilled work with the hand, more generally designating those visual arts which are actually practised by hand and associated with wearing apparel or decoration in the home. In a sense handicrafts may be considered as synonymous with arts and crafts (*q.v.*), only of a less broad meaning; arts and crafts including those arts which are practised by hand and those which are practised with the aid of a machine.

HANDL, JACOB, also **HÄNDL** or **HÄHNEL** (c. 1550-1591), German composer, was born in Carniola about 1550. The nickname of *GALLUS*, by which he was generally known, was a play on his surname Hähnel, "little cock." He is known to have been in the service of the Bishop of Olmütz as master of the chapel about 1579, but is principally associated with Prag, where he was for many years organist of St. Johann am Ufer. His death took place at Prag on July 18, 1591. Although he hardly merited the name, freely given to him, of "the German Palestrina," he was undoubtedly an important figure in his day. His music shows a definite leaning towards the homophonic style which was so soon to take the place of 16th century polyphony. Most of his works were published in his lifetime, the most important being his "opus musicum," containing motets for the whole church year (Prag, 4 vols., 1586-90).

Other works are: 16 masses (1580); *Epicedion harmonicum* (1589); *Moralia* (1596); a motet a 4: *Ecce quomodo moritur justus* (used by Handel in his Funeral Anthem) and others for 5, 6 and 8 voices, printed in Bodenschatz's *Florilegium portense*; 11 motets, 3 *responsoria*, a *Miserere*, a *Christus factus est*, and a *Te Deum* are included in Proske's *Musica divina*. A selection of his motets with biographical notes will be found in *Denkmäler der Tonkunst in Oesterreich* vol. VI. 1 (1899). See Paul Piok, *Die Messen von Jakobus Gallus* (Vienna, 1917).

HAND PRESSES: see **PRINTING**.

HANDSEL, the O.E. term for earnest money; especially in Scotland the first money taken at a market or fair. "Hand"

indicates the actual putting of the money into the hand. Handsels were also presents or earnings of goodwill in the north; thus Handsel Monday, the first Monday in the year, an occasion for universal tipping, is the equivalent of the English Boxing Day.

HANDSWORTH. (1) A parliamentary division of Birmingham, England. Pop. (1921) 75,145. (See BIRMINGHAM.) (2) An urban district of Yorkshire, 4 m. S.E. of Sheffield. Pop. (1921) 15,893. In this neighbourhood are extensive collieries.

HAND TENNIS: see TENNIS.

HAND-TO-MOUTH BUYING. This American phrase describes a method, involving a notable change in the economic structure of American business, which is the purchase by jobber, retailer and consumer of only such small supplies of goods as are immediately saleable or appropriate for the moment. It was a radical departure from the long-prevailing custom of the jobber and retailer ordering and keeping in stock a large assortment of merchandise. Likewise, it was an important change in the buying habits of many American people.

Hand-to-mouth buying began on a large scale in 1921, but some of its contributing causes were produced by the outbreak of the World War in 1914. Almost every American industry was pressed to fill orders from Europe. When the United States entered the war in 1917, transportation of munitions and other war supplies became a prime object. Manufacturing production had been greatly increased, but the railroads were not equipped to handle the immense volume of goods for both war needs and private consumption. Jobbers and retailers were unable to secure promptly goods ordered from the manufacturers. With the war's end in 1918, there was a movement to meet the public demand for goods by over-stocking. In the summer of 1920 a widespread industrial depression set in; the public stopped buying; and dealers were left with overloaded and stale stocks of depreciated value. From the fear of again over-stocking, jobbers and retailers adopted the hand-to-mouth buying policy.

So rapidly did public taste for different styles in many articles change that manufacturers faced a problem of production, and jobbers and retailers felt that they could not afford to risk carrying a large quantity of goods. Great changes in consumer demand had taken place, and these in turn seriously affected mass production of goods. General automobile ownership had removed suburban and rural isolation. Fashion magazines penetrated in the remotest places, and cinema pictures everywhere vividly presented the latest modes. The result was a general popular awakening to an appreciation of "smart" garb and well-designed objects, whether of house decoration, home architecture or other possessions. Consumer demand became more selective and individualistic; manufacturers found that they could no longer impose old stocks unsaleable in cities upon small towns and rural inhabitants. In its condition of post-war prosperity, the American public demanded constant changes in styles and was both able and willing to pay for them. No prudent merchant was disposed to buy more of an article than he thought could be sold within six to eight weeks. The great increase in commercial rents in the various American cities caused storekeepers to take smaller shops. From 1918 to 1928 these rent increases approximated 300%. Curtailment of store space supplied another reason for hand-to-mouth buying, and the development of motor truck transportation made it more feasible. By motor truck delivery small orders were rushed to their destination.

In 1926 the Farmers Loan and Trust Company of New York city sent a questionnaire to American leaders in industrial and economic thought on the causes and results of hand-to-mouth buying. Many bankers, department store owners, and executives of industrial corporations agreed that large inventories were an evil under modern conditions and that hand-to-mouth buying had become established as a permanent factor.

HAND TREE (*Cheirostemon platanoides*), a tree of the family Sterculiaceae, native to Mexico, which takes its name from the peculiar formation of the flowers, the five bright red stamens of the calyx projecting in such a way as somewhat to resemble the fingers of a human hand—the corolla being absent. It is related to the Baobab of West Africa.

HANDWRITING. Under PALAEOGRAPHY and WRITING, the history of handwriting is dealt with. Questions of handwriting come before legal tribunals mainly in connection with the law of evidence. Proof by comparison of handwritings, with a reference if necessary to three experts as to the handwriting which is to be used for the purposes of comparison, is provided for in the French Code of Civil Procedure (arts. 193 *et seq.*); and in Quebec (Code Proc. Civ. arts. 392 *et seq.*) and St. Lucia (Code Civ. Proc. arts. 286 *et seq.*), the French system has been adopted with modifications. Comparison by witnesses of disputed writings with any writing proved to the satisfaction of the judge to be genuine is accepted in England and Ireland in all legal proceedings whether criminal or civil, including proceedings before arbitrators (Denman Act, 28 & 29 Vict. c. 18, 55, 1, 8); and such writings and the evidence of witnesses respecting the same may be submitted to the court and jury as evidence of the genuineness or otherwise of the writing in dispute. It is admitted in Scotland (where the term *comparatio litterarum* is in use) and in most of the American States, subject to the same conditions. In England, as in the United States, and in most legal systems, the primary and best evidence of handwriting is that of the writer himself. Witnesses who saw him write the writing in question, or who are familiar with his handwriting either from having seen him write or from having corresponded with him, or otherwise, may be called. In cases of disputed handwriting the court will accept the evidence of experts in handwriting; *i.e.*, persons who have an adequate knowledge of handwriting, whether acquired in the way of their business or not, such as solicitors or bank cashiers (*R. v. Silverlock*, 1894, 2 Q.B. 766). In such cases the witness is required to compare the admitted handwriting of the person whose writing is in question with the disputed document, and to state in detail the similarities or differences as to the formation of words and letters, on which he bases his opinion as to the genuineness or otherwise of the disputed document. By the use of the magnifying glass, or, as in the Parnell case, by enlarged photographs of the letters alleged to have been written by Parnell, the court and jury are much assisted to appreciate the grounds on which the conclusions of the expert are founded. Evidence of this kind, being based on opinion and theory, needs to be very carefully weighed, and the dangers of implicit reliance on it have been illustrated in many cases (*e.g.*, the Beck case in 1904; and see *Seaman v. Netherclift*, 1876, 1 C.P.D. 540). Evidence by comparison of handwriting comes in principally either in default, or in corroboration, of the other modes of proof. It has been held in England that in a criminal case where a question of handwriting is raised, the jury should have the assistance of expert evidence (*R. v. Rickard*, 1918, 26 Cox C.C. 318).

GRAPHOLOGY

The systematic attempt to read character from handwriting is termed graphology. Extravagant and unsubstantiated claims have been made in this field. Graphologists have organized a system of reading personality on the basis of such graphic elements as size, line-quality, slant, alignment, continuity and proportions above and below the line. Size has been claimed to be symptomatic of self-feeling. Unusually large handwriting is said to characterize the ambitious, imaginative person; very small writing, the pedantic person. It is, however, recognized that there may be more than one cause for the same effect. Minute writing may be due to myopia; magnification of script may mask loss of motor control. The graphologists claim that slant and alignment are symptomatic of emotivity; extreme slant to the right betokens emotional susceptibility; to the left, coldness, emotional repression. Falling alignment signifies pessimism; rising alignment, optimism, ambition.

The psychology of handwriting puts graphological affirmations

to the test. Binet, for example, checked by means of controlled experiments four assumptions of the graphologists, their claim to read from handwriting: sex, age, intelligence and character. He found that the success of graphologists in detecting sex from handwriting ranged from 63 to 78.8% and under favourable variable conditions might reach 90%. Inversions of sex signs were, however, common. Many women were found to write masculine hands and a few men feminine ones. A sexless hand was also discovered. The interpretation of the results is ambiguous since sex in writing may be an outcome of social factors. On the basis of differences in pressure, speed, size and rhythm, Meumann and Awramoff have also concluded that there are masculine and feminine writing-types. Binet found the graphologists could estimate age on the average within about ten years. They were somewhat successful in separating the hands of geniuses from those of average individuals but could not select accurately the handwriting of criminals. Other experimentalists have tested out other assumptions of the graphologists. Hull and Montgomery obtained negative results. Downey found some evidence of positive correlation between preoccupation with details and small filiform writing and between an explosive psychic make-up and general pattern.

Identification of Handwriting.—The handwriting expert interested in the identification of hands should not be confused with the graphologist who seeks to read character from handwriting. The former may have little patience with the claims of the latter. He may urge that individuality of handwriting is wholly a product of external factors such as the system of handwriting learned, the writing apparatus used, occupational requirements and the like, and yet state, as does Osborn, that the mathematical probability of two complete handwritings being identical is one in something more than 68 trillions.

Identification of handwriting is a matter of great importance in law cases which involve questioned documents. The handwriting expert utilizes the enlarged photograph, the document microscope, the colour microscope, designed for recording the tints and shades of ink and delicate scales for determining line-width and similar graphic details. He also applies stereoscopic photography to determine which line was written first, in the case of lines that cross, and to discover the presence of erasures and changes in paper-fibre. He has also stimulated discussions concerning the limits of variability and of disguise in the hands of individuals.

Graphic Pathology.—Medical graphology is concerned with the changes that take place in writing with the incidence of organic or neural diseases or mental disorders. In the case of neural disturbances, changes in writing may result which are, to a certain extent, symptomatic of a given disease. Such changes occur in handwriting in paralysis agitans, tabes, paresis, writer's cramp, senile deterioration. They consist largely of tremors of various sorts, of ataxia or disorder of form, or involve great increase or decrease in graphic size or blurring or fusion of letters or exaggerated spacing of letters. Mental disturbances may also affect handwriting. There may be an exaggeration of certain characteristics that appear in script produced under emotional excitement or extreme inhibition, for example, the magnification of movement in the writing of the maniac and its uphill trend, or the tiny script of the melancholiac with its falling alignment. The curiously decorated signatures that betoken grandeur of ideas or morbid vanity may also be cited in this connection, as also the elaborate paraphs or flourishes which are made at the end of a signature sometimes in such a way as to suggest that the penman is protecting himself against blows from the outside. Disturbances of handwriting may possibly result from organic diseases. Very broad claims have been made by Duparchy-Jeanneze concerning the possibility of using various graphic signs in the diagnosis of stomach, liver, heart and gastro-intestinal diseases. Curious applications of medical graphology have been made in biographical studies. The question has been raised, for example, whether it is possible to determine from the six defective signatures of Shakespeare that are admittedly genuine, whether or not the poet suffered from a given disease. Beethoven's writing has also been scanned to determine the changes that appear in the script of deaf patients.

A curious modification of writing is found in reversed or mirror-

script which can be restored to the usual form by reflection from a mirror. It has been thought that mirror-writing is the normal writing of the left hand but it is sometimes written spontaneously by the right hand and it is a common occurrence among young children who are just learning to make letters or digits. The most famous instance of mirror-writing is that of Leonardo da Vinci. See CALLIGRAPHY.

HAN DYNASTIES: see CHINA, HISTORY; CHINESE PAINTING; CHINESE SCULPTURE.

HANFORD, a city in the central part of California, U.S.A., 30m. S. of Fresno; the county seat of Kings county. It is served by the Santa Fe and the Southern Pacific railways. The population was 5,888 in 1920; estimated locally at 7,850 in 1928. It lies in the irrigated part of the rich San Joaquín valley, where farming, fruit growing and dairying are the principal industries. The city was incorporated in 1891.

HANGAR: see AIRSHIP SHEDS.

HANGCHOW, one of the most notable of the historic cities of China (30° 15' N., 120° 16' E.). Its significance is largely the product of its position. It lies at the mouth of the basin of the Tsien-tang which drains W. Chekiang, and at the head of the bay of Hangchow into which the Tsien-tang falls. As the natural link between the thickly-peopled plains on either side of Hangchow bay and as the outlet of West Chekiang, Hangchow has come to be the capital of Chekiang province. It has had a wider significance through its position on the south margin of the Yangtze delta and through its participation in the cultural development of the deltaic cities. It gathers up the southern ends of the waterways of the delta and is the southern terminus of the Grand canal which was, from the time of the Mongols to the mid-19th century, the main avenue of communication between the Yangtze delta and Peking. Yet the greatest days of Hangchow were before the completion of the Grand canal as a through route between north and south. It was during the later Sung dynasty (A.D. 1127-1280), when the Chinese had retreated before the Tartars south of the Yangtze, and had established their capital at Hangchow which became the scene of the intense literary activity of that period, that the city reached the height of its importance. Hangchow was then popularly known as King-sze (the capital), from a corruption of which Marco Polo's *Kinsai* was derived.

Hangchow has been a commercial centre of great importance from the T'ang period onwards. Although one of the points where the system of inland waterways which thread the Yangtze delta reaches the sea, Hangchow itself has never been a port for sea-going vessels. From the T'ang to the Yüan periods it utilized Kanfu (or Kanpu) farther down Hangchow bay, and with the continued silting of the bay, its sea-going trade has had to pass through Shanghai. The total trade of the port—Hk. Tls. 29,964,042 in 1926—is of about the same bulk as that of Soochow or Chinkiang, which are also within the delta and on the Grand canal. Hangchow is of industrial as well as of commercial importance. The most important industry is silk manufacture, for north-west Chekiang is a famous sericultural region. Like Nanking, Hangchow is a silk-weaving rather than a silk-reeling centre. A considerable number of rice-hulling and cleaning mills reflect the rice culture of the surrounding plains.

The city itself is built at the foot of a beautiful range of hills (the Tien-mu shan or Eye of Heaven mountains) and by the shores of the famous Si-hu, the Western lake. The beauty of its buildings and gardens equals the charm of its situation among

hills and valleys studded with some of the most famous monasteries in China. Hence the Chinese proverb: "There is Heaven above and Soochow and Hangchow below." To Marco Polo it was incomparably the finest city in the world. This beauty was sadly tarnished by terrible devastations during the Tai p'ing revolt in 1861, but the city, in a somewhat modernized form, has largely recovered its prestige, and with a population of 650,000 still ranks as one of the greatest cities of China.

Hangchow was, especially during 1927 and 1928, of great importance to the contending powers in China. When the Nationalist party made Nanking the capital of the republic, Hangchow immediately sprang into greater prominence as the port of that city. New regulations were formulated for the defence of the port against river-pirates and a shore Customs board was set up to deal with the smuggling which was a profitable undertaking. Early in 1929 there was a clash between the Nationalists and the Customs authorities over a supply of opium which arrived at Hangchow destined for Nanking. Hangchow itself has not frequently suffered the outrages common to most important cities in the active area of hostilities and still preserves many of its beauties in spite of its increased commercial and industrial importance.

HANGING, in ancient days, a mark of indignity practised on the lifeless form of criminals. As a form of execution it does not appear in the Mosaic legislation. It is probable that the Chief Baker in the time of Joseph (Genesis xli. 13) was thus exposed to shame after being killed. Under Persian rule gallows were certainly used as a method of execution. The case of Haman exemplifies this method (Esther ii. 23, vii. 9-10). It was derived by the Anglo-Saxons from their German ancestors (Tacitus, *Germ.* 12). In England Henry I. decreed that all thieves taken should be hanged (*i.e.*, summarily without trial), and by the time of Henry II. hanging was fully established as a punishment for homicide; the "right of pit and gallows" was ordinarily included in the royal grants of jurisdiction to lords of manors and to ecclesiastical and municipal corporations. In the middle ages every town, abbey, and nearly all the more important manorial lords had the right of hanging. From the end of the 12th century the jurisdiction of the royal courts gradually became exclusive. Hanging was substituted in 1790 for burning as a punishment of petty treason (*see* TREASON), and in 1814 for beheading as a punishment for male traitors. Formerly in the worst cases of murder it was customary after execution to hang the criminal's body in chains near the scene of his crime. This was known as "gibbeting," and, though by no means rare in the earliest times, was, according to Blackstone, no part of the legal sentence. It was not until 1752 that gibbeting was recognized by statute. The Act (25 Geo. II. c. 37) empowered the judges to direct that the dead body of a murderer should be hung in chains, in the manner practised for the most atrocious offences, or given over to surgeons to be dissected and anatomized, and forbade burial except after dissection (*see* Foster, *Crown Law*, 107, Earl Ferrers' case, 1760). The Act of 1752 was repealed in 1828, but the alternatives of dissection or hanging in chains were re-enacted and continued in use until abolished as to dissection by the Anatomy Acts in 1832, and as to hanging in chains in 1834.

In Great Britain criminals are executed by fracturing or dislocating the first three cervical vertebrae and so damaging the vital centres in the spinal cord. This is done by placing a noose round the neck and allowing the condemned to fall a distance of 6 to 8 ft. before the rope takes the strain. The knot is placed either behind the ear or under the chin, so that the neck may be more readily broken. Under the Act of 1868 (31 and 32 Vict. c. 24), which was adapted from similar legislation already in force in the Australian colonies convicted murderers are hanged within the walls of a prison. The sentence of the court is that the convict "be hanged by the neck until he is dead." The execution of the sentence devolves on the sheriff of the county (Sheriffs Act, 1887, s. 13). A public notice of the date and hour of execution must be posted on the prison walls not less than 12 hours before the execution and must remain until the inquest is over. The persons required to be present are the sheriff, the gaoler, chaplain

and surgeon of the prison, and such other officers of the prison as the sheriff requires; justices of the peace for the jurisdiction to which the prison belongs, and such of the relatives, or such other persons as the sheriff or visiting justices allow, may also attend. The death of the prisoner is certified by the prison surgeon, and a declaration that judgment of death has been executed is signed by the sheriff. An inquest is then held on the body by the coroner for the jurisdiction and a jury at which it is usual to allow the attendance of some representatives of the press. (*See* further CAPITAL PUNISHMENT.)

United States.—Capital punishment has been abolished in Kansas, Michigan, Minnesota, North Dakota, Rhode Island and Wisconsin, except in North Dakota and Rhode Island where it applies if a person serving a life sentence commits murder. Electrocution has been substituted for hanging in Alabama, Arkansas, the District of Columbia, Florida, Georgia, Illinois, Indiana, Kentucky, Massachusetts, Missouri, Nebraska, New Jersey, New York, North Carolina, Ohio, Oklahoma, Pennsylvania, South Carolina, South Dakota, Tennessee, Texas, Vermont and Virginia. Kentucky still inflicts hanging for rape. Execution is by lethal gas in Nevada and in Utah the condemned person has the option of death by hanging or shooting. In the other States hanging remains as the method of legal execution. In States having execution, it is invoked for first degree murder, although in some States the jury may bring about life imprisonment by urging mercy. A few of the States permit execution for kidnapping and rape.

HANGÖ, a growing port and sea-bathing resort situated on the promontory of Hangöudd, to the extreme south-west of Finland, in 59° 46' N., 22° 57' E. Pop. (1925) 7,000. There are two powerful ice-breakers and the port is kept open all the winter, and the mole has been lengthened to Högholmen, which the largest ships can enter. Warehouses and quays are under construction. The exports are butter, wood, pulp, paper, tar, game and skins, and the imports cotton, coal, sugar, coffee, wines and spirits, iron and textiles. It is connected by railway with Helsingfors and Tammerfors, and is the centre of the Finnish butter export. During the period of emigration, owing to political troubles with Russia, over 12,000 Finns sailed from Hangö in 1901.

HANIËL VON HEIMHAUSEN, EDGAR VON (1870—), German diplomatist and official, was born at Ruhroft on Dec. 12, 1870. He studied at Bonn and Berlin, and entered the diplomatic service in 1900. He served in the principal European embassies before he was attached (1911-17) to the embassy at Washington. He was a member of the armistice commission at Spa and of the peace delegation at Versailles. He was then secretary of State in the Foreign Office, and in 1923 became representative of the *Reichsregiment* at Munich.

HANIHARA, MASANAO (1876—), Japanese statesman, was born in Yamanashi-Ken. He graduated from Waseda university, Tokyo, in 1897 and entered the diplomatic service. In 1899 he went to the legation at Seoul (Korea) as attaché, being transferred to Washington in the same capacity in 1901. After a year of service there, he was made secretary, invited specially to study American affairs, and later became chief secretary for foreign affairs. He felt that American-Japanese relations were unsatisfactory and wished to impress upon the citizens of the United States the necessity for friendly co-operation with the Japanese. He was sent to San Francisco as consul-general in 1916, remaining until the end of 1917. Returning to Tokyo he first became director of political affairs and then, in 1919, vice-minister for foreign affairs. As vice-minister he was one of the four delegates to the Washington Conference 1921-22. In 1923 he was appointed Japanese ambassador to Washington, and it is maintained in America that his reference, in a public speech, to the "regrettable consequences which would follow the passage" of the immigration bill, was responsible for the bill becoming law. The Japanese Government realizing that some blunder had been made, recalled Hanihara in 1924.

HANK: *see* YARN.

HANKA, WENCESLAUS (1791-1861), Bohemian philologist, was born at Horenioves, Bohemia, on June 10, 1791. In

1817 Hanka alleged that he had discovered some ancient Bohemian manuscript poems (the *Königinhof* ms.) of the 13th and 14th century in the church tower of the village of Kralodwor, or *Königinhof*. These were published in 1818, under the title *Kralodvorsky Rukopis*, with a German translation by Swoboda. Dobrowsky pronounced *The Judgment of Libussa*, another manuscript found by Hanka, an "obvious fraud," and, though Dobrowsky afterwards retracted, the ms. is usually regarded as a forgery. The originals were presented by the discoverer to the Bohemian museum at Prague, of which he was appointed librarian in 1818. In 1848 Hanka, who was an ardent Panslavist, took part in the Slavonic congress; he was the founder of the political society *Slovanska Lipa*. He was elected to the imperial diet at Vienna, but declined to take his seat. In the winter of 1848 he became lecturer and in 1849 professor of Slavonic languages in the University of Prague, where he died on Jan. 12, 1861.

His works include: *Hankow Pjsne* (Prague, 1815), a volume of poems; *Starobyta Skladani* (1817-26), in 5 vols.—a collection of old Bohemian poems, chiefly from unpublished manuscripts; editions of various texts; and a Czech grammar.

HANKEY, SIR MAURICE PASCAL ALERS, G.C.B. (1919) (1877-), British soldier and politician, was born on April 1, 1877, and educated at Rugby. He joined the Navy in 1895, and served in the Mediterranean from 1899 to 1901. He was then appointed to the Naval Intelligence department (1902-1906) and afterwards served as secretary to the committee of imperial defence (1912), the war cabinet (1916), the imperial war cabinet (1917), the imperial conferences of 1921, 1923 and 1926 and the London conference on reparations (1924). He also acted as secretary to the British delegation at the peace conference in 1919, the Washington conference in 1921, and the Genoa conference in 1922. In 1923 he was appointed clerk of the Privy Council. He was made G. C. M. G. in June, 1929.

HANKOW, the greatest commercial city of Central China in 30° 32' N. and 114° 19' E. Hankow itself lies on the north side of the Yang-tze at the junction of the Han-kiang with the main river. Immediately opposite, in the angle of junction, is the older city of Hanyang and a little below the confluence, on the south bank of the Yang-tze, is the ancient metropolis of Wuchang, the capital of Hupeh province. Hankow, Hanyang and Wuchang really constitute a single urban unit of vast dimensions known to the Chinese under the composite name of Wu-Han. The total population in 1926, as estimated by the Chinese Maritime Customs, was 1,583,900.

Communications.—This triple city of Wu-Han has an almost unrivalled geographical centrality which gives its site immense commercial significance. The Hupeh basin in which it lies is pre-eminently the central basin of China, the very heart of the country, and the converging point of routes from every point of the compass. If a line is drawn connecting the chief emporia along the periphery of China proper (Peking, Sianfu, Chengtu, Yunnanfu, Canton, Shanghai) we get a roughly circular figure with Wu-Han nearly in the centre. The Yang-tze, the greatest of China's arterial waterways, is navigable for large ocean-going vessels, except during the winter dry season, up to the site of the city which can therefore be considered as the head of ocean navigation, although 600 miles from the coast. Upstream between Hankow and Ichang, at the outlet of the Yang-tze gorges, it is navigable for vessels of considerable size, and midway in this stretch, at Yochow, the river is the outlet for the large Tung-ting lake into which flows from the south the Siang, the main artery of Hunan, and from the south-west the Yuen-kiang, affording the chief route to Kweichow and south-west China generally. To the east the Po-yang lake, strictly analogous to the Tung-ting lake, receives the waters of the Kan, the second of the two great ways to the south through the south China highlands. Kiukiang, at the Yang-tze outlet of this system, may be regarded largely as a feeder of Wu-Han which is centrally placed in relation to the twin basins of Tung-ting and Po-yang.

To the west of the Hupeh basin is the trough of the Yang-tze gorges, difficult indeed, but the only practicable route by which the Red basin of Szechwan can be brought into relation with the

heart of China and the ocean. The construction of special steamers for negotiating the gorges even during the dry season now greatly facilitates trade between Chung-king and Hankow. From the north-west comes the Han, navigable for 300 miles above Hankow and the chief route to Sianfu and north-west China.

The importance of this convergence of river-routes is now increased by the fact that the main trunk railway of China, destined to link Peking with Canton, here intersects the Yang-tze. The railway is in two main sections: the completed section from Peking to Hankow, and the incomplete section from Wuchang to Canton. The railway southwards has been finished to a point beyond Changsha and a branch line puts Wu-Han into direct rail connection with the coalfield at Pinghsiang. Among projected railways two are of great importance, an urgently needed line to the Red basin and another to south-west China utilizing the valley of the Yuen-kiang. As the meeting point of maritime, river and rail transport, Wu-Han has almost unique advantages as a collecting and distributing centre and its position in this respect may be compared with that of Chicago.

It is connected by regular lines of steamers with Shanghai, Ichang, Changsha and other river ports and is the focus of an enormous junk traffic. It is the chief entrepôt for the Central Yang-tze provinces and for west and south-west China particularly for tea, cotton, silk, timber (from western Hunan by the Yuen-kiang), wood-oil and hides.

Industries.—Hankow was one of the first inland cities of China to be opened to foreign trade (1858) and its development as a port in close contact with Europe brought it early under the influence of western industrialism. Hanyang was selected by the viceroy Chang Chih-tung in 1891 as the site of the first modern iron and steel works in China. This became the property of the Han-yeh-ping Iron and Steel Company, organized in 1908, one of the chief industrial corporations of the middle Yang-tze valley, owning, in addition to the Hanyang iron and steel works, the Tayeh iron mines and the collieries of the Pinghsiang coalfield. This company has been largely financed by Japanese loans and one of the most important concessions obtained by Japan in 1915 was an undertaking from the Chinese Government "not to confiscate the company nor, without the consent of the Japanese capitalists, to convert it into a state enterprise, nor cause it to borrow and use foreign capital other than Japanese." In recent years this company and also the Yang-tze engineering works have suffered severely as a result of economic and political disturbances but Wu Han is likely to remain one of the chief centres of the Chinese iron and steel industry.

It is also an important centre of textile manufactures, although at present ranking far behind Shanghai. At the end of 1925 there were 27 weaving mills in Hankow, 6 in Wuchang and one in Hanyang. The cloths produced are mainly plain cloths, including woollen and cotton mixtures and fancy cloths, including artificial silk and brocades, the demand for which is increasing on the Wu-Han market. Dependent on this industry are a large number of dye works, the dyers in the majority of cases being weavers as well. There are five modern-style cotton mills, four of which are in Wuchang. In this connection it may be noted that American varieties of cotton have so far yielded much better results in the Hupeh basin than in the Yang-tze delta and that the area under cotton in the region surrounding Wu-Han has been steadily increasing.

Another large industry based on local production is represented by the rice mills of which there are over 30 in Wu-Han, all of them employing modern machinery. In addition there are several oil mills, utilizing the large local supplies of beans and many important refineries of wood or *tung* oil, which, as a substitute for linseed and other oils, has a large American and European market. There are also flour-mills, cement works, soap and albumen factories, distilleries and a large number of miscellaneous industries. Hankow is also a great banking centre.

Prior to the political disturbances of 1926-27, the rapid increase in Hankow's foreign trade was very remarkable. The value of the trade coming under the cognisance of the Maritime Cus-

toms in 1925 was HK. Tls. 288,761,077 made up as follows: net Foreign imports, 69,365,189; net Chinese imports, 64,309,105; exports, 155,086,283.

Political Significance.—Both on account of its intrinsic importance and its situation in relation to the chief routes, the Wu-Han group of cities has figured prominently in the troubled political history of modern China. The revolution of 1911 broke out in the barracks at Wuchang and the low ridges, particularly the Serpents' ridge at Wuchang, which here cross the marshy basin, were of great strategic importance in the subsequent fighting. The line of heights overlooking the Han was the scene of the principal struggle between the imperial and revolutionary troops, the main objective being the government arsenal at Hanyang. More recently, the capture of Hankow by the Nationalist armies, advancing northwards from Kwangtung (December 1926), marked the extension of Nationalist power to the middle Yang-tze. It was followed by a serious mob onslaught on the British Concession, the charge of which passed into the hands of the Chinese and for a time business was completely suspended. Finally an agreement was concluded providing for the dissolution of the British Municipal Council and the setting up of a Chinese municipality modelled on that already set up for the former German Concession in Hankow but Sino-British in composition. The events at Hankow were also followed by the important communication (Jan. 27 and 28, 1927) to the Chinese authorities both at Peking and Hankow of the proposals of the British Government for modifying their position under the treaties to meet Chinese Nationalist aspirations. Subsequently Hankow was for a short time under the control of a "Communist" Government in opposition to the Nationalist Government at Nanking.

HANLEY, market town; Stoke on Trent county, municipal and parliamentary borough, Staffordshire, England. Pop. (1921) 77,786. In 1910 it amalgamated with neighbouring towns to form the municipal borough of Stoke-on-Trent (*q.v.*) which in 1925 became a city.

HANN, JULIUS (1839-1921), Austrian meteorologist and climatologist, was born near Linz, Upper Austria, on March 23, 1839. In 1865 he became editor of the *Zeitschrift der Oesterreichischen Gesellschaft für Meteorologie*, and from 1877 was occupied in the Central Meteorological Institute at Vienna. In 1873 he was appointed professor of physics at the University of Vienna. He acquired a world-wide reputation for his works on atmospheric dynamics and thermodynamics, the "atmospheric pulse," cyclones and climatology. His principal works are *Die Erde als Ganzes; Die Atmosphäre und Hydrosphäre* (1872); *Handbuch der Klimatologie*, 3 v. (1908); *Lehrbuch der Meteorologie*, 3d ed. (1914) and many papers in his own *Zeitschrift* and the reports of the Akademie der Wissenschaften. He died in Vienna on Oct. 1, 1921.

HANNA, MARCUS ALONZO (1837-1904), American politician, was born at New Lisbon (now Lisbon), Columbia county (O.), on Sept. 24, 1837. In 1852 he removed with his father to Cleveland. He received his education in the public schools of that city and at the Western Reserve university. He was associated with his father in the wholesale grocery business and became a member of the firm. In 1867 he entered into partnership with his father-in-law, Daniel P. Rhodes, in the coal and iron business. In 1877 the firm became M. A. Hanna & Company and was extended to include the ownership of a fleet of lake steamships constructed in its own shipyards and the control and operation of valuable coal and iron mines. Hanna became largely interested in street railway properties and in various banking institutions, and after 1880 became prominent in the affairs of the Republican party in Cleveland. In 1884 and 1888 he was a delegate to the Republican national convention and was associated with William McKinley in the management of the John Sherman canvass. It was not, however, until 1896, when he personally managed the canvass that resulted in the Republican presidential nomination for William McKinley that he became known throughout the United States as a political manager of great adroitness, tact, and resourcefulness. He was chosen chairman of the Republican national committee and managed with consum-

mate skill the campaign of 1896 against William Jennings Bryan and "free-silver." In March 1897 he was appointed, by Governor Asa S. Bushnell (1834-1904), U.S. senator from Ohio. In the Senate, to which in Jan. 1898 he was elected for the short term ending March 3, 1899, and for the succeeding term, he was recognized as one of the principal advisers of the McKinley administration and his influence was large.

He took a deep and active interest in the problems of capital and labour, was one of the organizers (1901) and the first president of the National Civic Federation, whose purpose was to solve social and industrial problems, and in Dec. 1901 became chairman of a permanent board of conciliation and arbitration established by the Federation. After President Roosevelt's policies became defined Senator Hanna was regarded as the leader of the Conservative branch of his party and a possible presidential candidate in 1904. He died at Washington on Feb. 15, 1904.

HANNEN, JAMES HANNEN, BARON (1821-1894), English judge, was born at Peckham in 1821, and educated at St. Paul's and at Heidelberg university. Called to the bar in 1848, he rapidly made his name both in his own profession and in journalism. In 1868 Hannen was appointed judge of the court of Queen's Bench; in 1872 he became judge of the Probate and Divorce court, in 1825 president of the probate and admiralty division of the High Court of Justice, and lord of appeal in ordinary in 1893. His name is associated with many famous cases, notably that of *Farrar v. Close*, which affected the legal status of trade unions. He presided over the Parnell commission, and is said to have written a large part of the report himself. Hannen was one of the British arbitrators in the Bering sea enquiry in Paris in 1893. He died on March 29, 1894.

HANNIBAL (247-183 B.C.), Carthaginian general. The name of Hannibal was a very common one in Carthage, but the most illustrious of its bearers was the son of Hamilcar Barca. Born in 247 B.C., at the age of nine Hannibal was taken by his father to Spain, after swearing eternal hatred against the Romans. In Spain he was trained by his father in the art of war. He also accompanied him on the expedition in the course of which Hamilcar, having assured the safety of his young son, was killed by the rebellious Oretani (229). Hannibal remained in Spain during the term of government of his brother-in-law, Hasdrubal, who succeeded Hamilcar Barca, and he served under Hasdrubal for some years. On the latter's death (221), Hannibal, at the age of little more than 25, assumed command of the army and province of Spain. In 221 also, he conducted a campaign against the Holcades, and in 220 he moved against the Vaccaei, and overcame the Carpetani in a battle near the Tagus. In the following year, notwithstanding a warning received from Roman ambassadors, he laid siege to Saguntum, the only city in eastern Spain south of the Ebro which still resisted his armies, and he took it after an eight months' siege. The Romans, who had threatened war if Hannibal should attack Saguntum, now demanded satisfaction from Carthage and, failing to obtain it, declared war. Thus began one of the most terrible wars of antiquity, the Second Punic War.

Inasmuch as he rejected the Roman warning, it is beyond dispute that Hannibal must bear the responsibility in history for initiating the war. On legal grounds we may ask whether in virtue of the treaties, the Romans were entitled to intimate to Hannibal that he must not attack Saguntum, and there can be no doubt as to the answer, in view of what we learn from the very historians who consider that Hannibal's attack on Saguntum was a violation of the treaties. The treaty concluded by the Romans with Hasdrubal prohibited the latter from crossing the Ebro in arms. Saguntum, however, is south of that river, though certain ancient historians committed the gross geographical error of placing it to the north. Again, it is by no means certain that the treaty contained a clause excluding the Greek colonies from the Carthaginian sphere of influence; but even if there was any such clause it did not apply to Saguntum, for it is a mere fable, due to the likeness of names, that Saguntum was a colony of Zacyn-

thus; it was undoubtedly an Iberian city, as is shown by its coins. While, however, legally the Romans had no right to intervene on behalf of Saguntum—their own alliance with the Saguntines constituting a violation of Hasdrubal's treaty, which, at all events implicitly, assigned the region to the south of the Ebro to the Carthaginian sphere of influence—politically it is clear that by attacking Saguntum Hannibal accepted responsibility for the war and all its consequences. He did so because he thought it necessary in order to uphold the position of Carthage as a great power, and at the same time he thought that he could win—not realizing the granite solidity of the Italic confederation centred in Rome, which he hoped to dismember by the hammer-blows of his army. Thus Hannibal's whole action was based on a grave and fatal error of valuation; but this error was inevitable, because he could have no idea of the solidity of the Roman confederation, which had never yet been tested, except partially and not very thoroughly in the time of Pyrrhus; he could only draw a fallacious analogy with the other, infinitely weaker, confederations with which he was acquainted from history or by personal experience. Granted that Hannibal believed in the possibility of a victorious war with Rome, and thought that Carthage was bound to initiate it in order to retrieve the disasters of the First Punic War, we must then consider whether the moment Hannibal selected was a good one, and whether his preparations and his plan of campaign were suited to the exigencies of that moment.

The moment itself could not have been better chosen. Later on, a victorious war in Italy would have been almost impossible. The Romans had indeed, during recent years, discomfited the Boii, and crossing the Po had subjugated the Insubres, but the power of the Gauls was not yet broken; hatred of the victors was still extreme, and the Romans had scarcely begun to establish themselves in the conquered territory. At that juncture, therefore, the valley of the Po offered Hannibal an excellent base for a war against Rome, with abundant recruiting material. Had the Romans but been able to consolidate themselves in the Transpadane, he could have had no such hopes. Indeed, from then onwards it was already beginning to be a little too late, and Hasdrubal, by allowing the Romans to conquer the Cisalpine Gauls, had paid dearly for the truce during which he had been left free to consolidate the Punic empire in Spain.

With regard to the plan of campaign, modern writers have discussed whether Hannibal was really its author or whether it was not essentially due to Hamilcar Barca, who had entered upon the conquest of Spain with the precise object of subsequently preparing for an invasion of Italy across the Alps with the help of the Gauls, who at that time were still not under Roman dominion. There seems no doubt that such was really Hamilcar's intention. That he nourished a deadly hatred for the Romans, that he prepared for a war of revenge after having been forced to give up Sicily to them and watch them seize Sardinia, and that his whole object in founding the empire in Spain was to prepare for that war, is beyond question. But he could have made use in two ways of the strength and wealth which Carthage drew from her Spanish empire against the Romans: either in the way which Hannibal afterwards chose, or by preparing to regain the command of the sea, which had been lost in the First Punic War. As, however, he did not direct the policy of Carthage along this latter channel, it is perfectly legitimate to conclude that it was he who laid the foundation of the plan of campaign which Hannibal subsequently carried out. Hannibal's merit consists in having adopted that plan and putting it into execution with unequalled genius.

Nevertheless, Hannibal's conduct of the war had two fundamental defects. One was that—as his father, Hamilcar Barca, had previously done in Sicily, when he tenaciously defended the last remnants of Carthaginian territory there—he failed to realize with sufficient clearness the absolute necessity of naval supremacy for a definitive victory in the great duel with Rome, and, taking the view that the predominance gained by the Romans in the First Punic War was unalterable, he made no serious attempt at preparing to dispute it. Thus he lessened the efficiency of his conduct of the war; for there is no doubt that the ultimate victory of Rome in the Second Punic War was essentially due to the fact

that her naval supremacy was maintained throughout.

Moreover, Hannibal, having to entrust the command of the Spanish forces which were left to themselves when he started for Italy to a tried and faithful officer, selected his brother Hasdrubal, who was certainly in every way loyal, but was very young and quite unequal to his heavy responsibilities—so much so, that he was not merely unable to make head for a moment against a really good general like Scipio (afterwards called Africanus), but was repeatedly defeated by mediocre leaders like the brothers Publius and Gnaeus Scipio, who had small resources and few troops at their command.

Having gone into winter quarters at Cartagena (219–218), Hannibal started slowly towards the Ebro in the spring of 218, not crossing the river till nearly the end of May; he then spent two months in operations against the tribes between the Ebro and the Pyrenees. This slow progress was intentional. He was anxious that his opponents should not have the slightest suspicion of his contemplated invasion of the Po valley, and (thinking it possible to stop him near the Rhone with the strong allied city of Marseilles as their base) should not soon enough make efficient preparations in upper Italy for the defence of the passes of the western Alps. This must have been exactly what the consul Publius Cornelius Scipio planned when, in the late summer of 218 (he had been detained in Italy by an unexpected rebellion of the Boii), he transported his army of two legions by sea from Pisa to the mouths of the Rhone. Here Scipio learned that Hannibal was already north of him, near the right bank of the river. When, after a successful cavalry reconnaissance, he moved northward along the right bank of the Rhone with his legions, he found that Hannibal had crossed the river and was proceeding northward on the left bank with intentions that were not too clear. Hannibal had been anxious to avoid a battle for the time being, and by marching northward to leave Scipio uncertain through which Alpine pass he had chosen to descend into Italy. In these circumstances, Scipio returned to the sea, embarked his legions for Spain with the intention of campaigning against the Carthaginian forces that still remained there, and accordingly entrusted the command to his brother Gnaeus, while he himself sailed from Marseilles for Pisa, whence he hastened to the Po to take command of the two legions stationed there to guard the territory and protect the two recently-founded Roman colonies near the river—Placentia and Cremona. Hannibal, however, as soon as he was assured that the Romans were not contemplating either pursuing him or closing the Alpine passes against him, returned southward, and crossing the pass of Mont Genève descended into Italy, into the valley of Susa. There he rested his forces, and having taken by assault the city of the Taurini tribe of Gauls, which offered resistance, proceeded to take the offensive, moving so rapidly in the direction of the Po as to anticipate Scipio's offensive.

Hannibal's march was thus, strategically, entirely successful. The Romans, failing to anticipate his movements, had not awaited him where with strong forces they could easily have given an initial and perhaps decisive check to his war worn and unacclimatized Africans—that is to say, in Piedmont, between Ivrea and Turin. After wasting time in seeking him near the Rhone, they had not acted rapidly enough to encounter him near the passes of the western Alps. Nevertheless, according to our tradition, this strategic success was very dearly bought, for between the Ebro and the Po Hannibal is said to have lost more than 50,000 men—about two-thirds of his army—reaching Italy with 20,000 infantry and 6,000 cavalry. This estimate of his losses is, however, quite inadmissible, and a critical scrutiny must reduce the total Carthaginian losses during the long march to not more than 5,000 or 10,000. It is indeed inconceivable that any army, after undergoing such hardships and suffering such enormous losses, could at once enter upon a victorious campaign; nor can it be supposed that Hannibal made such havoc of the best army Carthage ever had.

A cavalry skirmish between the Ticino and the Sesia, known as the battle of the Ticino, informed Scipio of the enemy's strength and led him to recross not only the Ticino but also the Po, abandoning the Transpadane to Hannibal and organizing his defence to the south of the Po, with the colony of Placentia as its base.

Near Placentia the Romans also concentrated the legions of the other consul, Tiberius Sempronius, who had been recalled from Sicily, where he was making preparations for a descent on Africa. Hannibal, crossing the Po higher up, moved in the direction of Placentia and encamped on the left bank of the Trebia. Here, crossing the river, the four Roman legions attacked him by order of Sempronius. The victory of the Trebia (about Dec. 218) was the first of the three great victories that Hannibal owed to his supreme tactical skill. This battle caused the Romans to abandon the whole of northern Italy except the colonies of Placentia and Cremona, so that in the following year (217) they stood on the defensive in the peninsula, with one army commanded by Gaius Flaminius at Arretium, and the other under Gnaeus Servilius at Ariminum. Eluding the vigilance of Flaminius, Hannibal now succeeded in crossing the Apennines and proceeded to ravage north-eastern Etruria under his very eyes; he then moved unexpectedly from Cortona along the northern shore of Lake Trasimene in the direction of Perugia, as if he intended to attack the other consul, Servilius, who was coming down by forced marches from Ariminum to effect a junction with his colleague in Etruria. Flaminius, who was in the enemy's rear, allowed himself to be surprised on the northern shore of Lake Trasimene, between the pass of Borghetto and Passignano, giving Hannibal the opportunity to gain the second of his great victories (June 217).

The dilatory and cautious methods of the dictator Fabius gave the Romans every facility for preparing for what they thought was bound to be the decisive campaign in the following year, but did not hinder Hannibal from ravaging along the Adriatic as far as Apulia and crossing into Campania, where he laid waste the fertile Ager Falernus. Thereafter, exhibiting admirable judgment and amazing skill in manoeuvre, he evaded the ambushes laid for him with considerably superior forces by the dictator, and returned to northern Apulia to take up his winter quarters (217-216).

Here, skirmishes near Geronium, one of which went in the Romans' favour and the other against them, did not alter the situation. It was altered by Hannibal, who at the end of the winter, without interference from the Roman army that was watching him, suddenly moved further south near the Aufidus and there seized the fortress of Cannae, where the Romans had a large supply depot. He thus secured stores for his army and at the same time had the advantage of moving into an undevastated area well suited to his skilful manoeuvring. Here, near the Aufidus, he was overtaken by the consuls for the year 216, Lucius Aemilius Paulus and Gaius Terentius Varro, with one of the largest armies that Rome had ever put in the field, about 50,000 strong (allowing for the exaggerations of tradition, which sets it at 80,000); their intention was to engage the enemy in a decisive battle. The Romans had two camps, one on either bank of the river, connected by a bridge; Hannibal had a camp on the right bank, further downstream.

The Romans drew up in order of battle on the left bank of the Aufidus, with their front facing the sea and their right resting on the river. If they were defeated, they thought they could fall back either on the left bank towards Asculum or Aquilonia, or, crossing the bridge between the two camps, on the right bank towards Canusium or Venusia. If he gave battle on the Apulian plain, Hannibal had to be prepared to fight with his back to the sea and risk a complete disaster if defeated, since he had no line of retreat. He relied, however, on the efficacy of a manoeuvre that has made the battle of Cannae famous, and has been successfully imitated several times in modern warfare, including the recent World War. Drawing up, as usual, his infantry in the centre and his cavalry on both wings, he advanced impetuously against the enemy with the middle part of the infantry line, consisting of the Gauls and Spaniards, while the detachments of Libyan infantry on both flanks remained inactive. The Romans not merely withstood the attack, but, with the weight of their deep columns, forced the enemy to give back beyond his original position. Thus the Libyan detachments, which had not moved during the attack, were projecting on both sides of the front as it bent before the drive of the legionaries; and now, at a given

signal, the Romans, who were penetrating like a wedge into the Carthaginian front, were assailed on either flank, while to complete the enveloping movement there came up from the rear the cavalry, who had routed the Roman cavalry on the wings, and half of whom, giving up the pursuit, had returned to the field of battle. Thus the enveloping movement was completely successful, and, notwithstanding its bravery and its superiority in numbers, the Roman army was utterly defeated. It will be realized that Hannibal's manoeuvre, which brought about the complete encirclement of the enemy, presupposes that the Romans were not so enormously superior in numbers as tradition would suggest. Otherwise, in order to surround them, he would have had to weaken his lines proportionately, to such an extent as to make it almost impossible for them to withstand the enemy's attacks.

This tremendous victory bore its natural fruits. After the battles of the Trebia and Lake Trasimene, the Italic confederation had remained intact. Not one of the confederate cities had passed over to the enemy. Now, however, this terrible hammer-blow detached from the granite mass of the confederation those parts that were least firmly joined to it—first northern Apulia with the powerful city of Arpi, then nearly all the territory of the Caudini and Hirpini, then most of the Lucanians and Bruttians, and lastly Capua, the second city in Italy.

Both by the ancients and in our own day Hannibal has been blamed for not profiting by his victory to march directly on Rome. The criticism is wholly unjustified. Defended by the strong and recently-repaired wall of Servius Tullius, inhabited by a warlike people not accustomed to quail, commanded by a senate that had always known how to face difficult moments, situated on a river that ensured its supplies even if Hannibal had succeeded in blockading it by land, Rome was in such a position that in all probability a move against it would not have had the very slightest hope of success, immediate or remote, and would have prevented Hannibal from exploiting his victory and gaining the practical benefit he obtained by inducing southern Italy to rebel. But at this point comes the end of Hannibal's wonderful series of successes, and the character of the war entirely changes. Legend ascribes this to the fact that Hannibal's troops went into winter quarters at Capua and thus lost the fighting spirit. In reality it was due to the new Roman strategy, which no longer allowed Hannibal to exploit that fighting spirit in great pitched battles. For the Romans now adopted the strategy suggested by Fabius, which earned him the name of *Cunctator*, the Delayer: never to accept battle when the enemy offered it, never to offer it on equal terms, never to attack him in his camp; but to destroy his army in detail as time and opportunity offered, to defend vigorously all the places that had remained loyal to Rome, to try to recover by force or fraud the places that had fallen into Hannibal's hands, profiting by Rome's numerical superiority and Hannibal's inability to keep the two theatres of war, Apulia and Campania, both under his own eye. This plan of campaign undoubtedly called on the Roman people and its allies for immense sacrifices in men and money, and for an indomitable tenacity. Hannibal, inferior in strength and not adequately supported by the Carthaginian Government because the Romans held permanent command of the sea, was obliged to substitute for his audacious and victorious offensives a cautious and not always successful defensive in which all the resources of his genius could not prevent the recovery by the Romans of one place after another that had fallen into his hands; for when superior Roman forces sat down before a city friendly to Carthage his only way of saving it was to give battle with inferior numbers, or to attack the Romans in their firmly-defended entrenchments, offering them the choice of easy victory.

Thus Hannibal's genius was nullified by the force of circumstances. It is not surprising that he lost ground and gained no more great victories in the field. Rather is it surprising that, always unconquered, threading his way among armies superior to his own, without any hope of adequate reinforcements, he succeeded for so many years in gaining still here and there a success, in winning here and there, even if not for long, another position, in retaining possession of a little Italian territory to the

end, and maintaining in it a strong and fairly large army. The weak point in the strategy of attrition adopted by the Romans was the immense effort for which it called, and it is doubtful whether the citizens and their allies would have been equal to such an effort year after year if they had not been comforted by visible successes, which raised their *moral* when it had been lowered by weariness. Nor must it be supposed that because he was reduced to passive resistance, Hannibal had any idea of allowing the Romans to dictate to him, or even of accepting the transformation of the war into a war of pure attrition, as Fabius desired. He was no longer, indeed, in a position to strike unaided such decisive blows as Cannae. But he could hope for some assistance that would change the aspect of the war in Italy—not so much from Africa, whence reinforcements could only reach him intermittently, as from Spain, if Hasdrubal had succeeded in destroying the small forces which the Romans could send there, or from Macedon, if King Philip V., who had been induced by news of Hannibal's success to take up arms against Rome in order to expel the Romans from their possessions in what is now Albania, had ventured to cross the Strait of Otranto and conduct an offensive war in Italy. Hannibal might also hope for assistance from Sicily, which, impressed by the Carthaginian victories, also rebelled against Rome immediately upon the death of the old king Hieron (215); or, at any rate, he might hope that the rebellious Syracusans, with effective help from Carthage, would succeed in containing considerable Roman forces for a long period, and thus indirectly assist him in his war in the peninsula. For reasons over which Hannibal had absolutely no control, none of these hopes were realized except the hope of reinforcements from Spain, which however, as we shall see, arrived too late to change the course of the war in Italy.

Meanwhile, however, the effects of the tenacious Roman resistance and the war of attrition were making themselves inexorably felt. In 213, Casilinum fell into the hands of the Romans, and later they recovered Arpi. True, Hannibal succeeded in surprising the Greek colony of Tarentum, the third city in Italy. This was not in every way of advantage to him; for as he never succeeded in occupying the citadel he was obliged to disperse his forces in a very dangerous manner, and meanwhile in his absence the Romans, with six legions, laid siege to Capua and surrounded it entirely with lines of circumvallation. Hannibal was not deaf to his allies' appeal, and in the spring of 211 he broke into Campania and offered battle to the Romans. They, however, refused to leave their fortified positions, and Hannibal was unable to relieve the city because he could not, without very great risk, persevere in his efforts to break the lines of circumvallation. Accordingly he made a very bold move. Leaving behind him the armies which were besieging Capua, he marched on Rome, and encamped three miles from the walls, between the Anio and the Tiber. The Romans were not intimidated; lining the walls with defending troops, instead of offering battle they sent a force out of the city to encamp a mile from Hannibal. In such circumstances it was madness to attempt an assault upon the walls, and equal madness to delay in the heart of the enemy's country, with difficult communications and with the danger of being surrounded by superior forces. Consequently, after a few days, Hannibal was forced to retire towards Bruttium, without realizing his hope of drawing away to the relief of Rome the powerful armies which were surrounding Capua, and thus securing an opportunity for a pitched battle and giving the besieged the respite of which they stood in need. A slight success over the consul Sulpicius Galba, who was following him up, did not recompense Hannibal for the complete strategic failure of his march, marvellous—almost miraculous—as it was in itself. Merely by remaining firmly at their posts the besiegers of Capua had decided the fate of the city, which not long afterwards opened its gates and received terrible punishment for its treachery. The fall of Syracuse a little earlier had marked the final destruction of the Greek power in Sicily. In 209, Hannibal received another heavy blow in the occupation of Tarentum by Fabius through treachery. In Spain also, after many years of indecisive warfare and following the momentary success represented by the rout of the two Scipios (of which,

however, the Carthaginians had not been capable of taking full advantage), their empire was breaking up under the blows of Scipio. At this juncture it occurred to Hasdrubal to go to help his brother in Italy with the troops which he could not usefully employ in the defence of Spain. In the fine season of 208, while Hasdrubal, retracing his brother's route, was descending the Alps and continuing in the direction of central Italy as far as the Metaurus, it would seem that Hannibal, with the object of effecting a junction with him, advanced as far as Larinum, in the country of the Frentani. Such, however, was the numerical superiority of the Romans that, while he himself was obliged to proceed northward with extreme slowness and caution, he was unable to prevent the concentration of considerable forces against his brother. The defeat of Hasdrubal at the Metaurus deprived Hannibal of his last hope of making a recovery in Italy, and the fatal news was conveyed to him by the severed head of his brother being cast by the Romans into his camp. Thereupon, abandoning all idea of an offensive, he retired into Bruttium, where he also concentrated the forces of those allies who had remained loyal to him. Here for four more years he withstood the Romans, fiercely contesting every step of their advance, and making them pay heavily for such successes as they gained by their strategy of attrition. Had they persevered in this strategy to the end, it is doubtful indeed whether they would have gained the final decisive victory, and even had they done so they would probably have paid for it by such immense sacrifices that they themselves would have fallen exhausted upon the corpses of their conquered adversaries. Now, however, Publius Cornelius Scipio, the young general who had displayed genius of such a high order in destroying, with very limited resources, the Carthaginian empire in Spain, was anxious to substitute a strategy consisting in boldly taking the offensive in Africa; and, despite the reluctance of the senate, in which a strong party headed by the aged Fabius was opposed to such an audacious policy, regarding it as dangerous and foolish, he succeeded in obtaining permission to carry out his design.

Scipio's marvellous victories, which broke Carthage's principal ally, Syphax, king of the Massaesylian Numidians, and threatened Carthage herself, ultimately compelled Hannibal to abandon Italy in the autumn of 203 in order to go to the help of his country. When he landed with his army at Leptis Minor and encamped near Hadrumetum, the Carthaginians, reduced to the last extremity, had already concluded an armistice and accepted preliminaries of peace with Scipio on extremely severe terms. Meanwhile the forces with which, a little earlier, Hannibal's other brother Mago had tried somewhat unsuccessfully to take the war into Liguria, also collected at Hadrumetum. Mago, recalled, had also embarked for Africa, but had died of wounds during the voyage. The large forces collected at Hadrumetum and the presence of their greatest general now induced the Carthaginians to try once more the test of arms. Almost at the very moment when the ambassadors were returning from Rome with the peace preliminaries approved, the Carthaginians—perhaps with Hannibal's connivance—violated the armistice concluded with Scipio, and the war broke out again. Scipio promptly recalled his faithful ally, Masinissa, king of the Massilian Numidians, whom he had sent into Numidia to fight against Vermina, son of Syphax, king of the Massaesylians, and allied like his father to the Carthaginians. Then, in the fine season of 202, he decided to climb the Bagrada in order to make a junction with the Numidians. Hannibal, who had likewise sent for Vermina, moved from Hadrumetum into the interior to join him, and encamped not far from Scipio, near Zama Regia. Scipio, instead of retiring towards his base, boldly moved forward towards Naraggara, between the Bagrada and the Muchtul, where he effected a satisfactory junction with the Numidian cavalry that Masinissa was bringing him. Hannibal, who had been following him, always in the vain hope of being joined by Vermina, now found himself in a serious position, being something like 125 miles from his base and in the presence of an enemy immensely his superior in cavalry. A meeting between the two commanders, at which Hannibal asked for peace, proved fruitless—because Scipio, realizing the strategic advantage he had

gained, insisted on terms more severe than those which had been agreed to before the breach of the armistice; so that there was nothing for it but battle. Scipio disposed the maniples of his legions in column, in three lines capable of operating independently, and defended his wings with the Italian and Numidian cavalry. Hannibal posted in his first line the Ligurian and Celtic mercenaries who had been under Mago's command, in his second line the native Libyans and the Carthaginian citizens, and in his third, further back as a true reserve, the flower of his army—the veterans of the Italian war. The front was protected by the elephants, the flanks by the cavalry. The elephants' assault was ineffectual owing to the able resistance of the Roman light troops, who succeeded in directing them through the columns of maniples, after passing which they were disposed of by other light troops without having done any serious damage. In the centre, the Carthaginian front line failed to resist the charge of the Roman *hastati*, and defeat seemed inevitable when Scipio, employing a manoeuvre which he himself had first used in the war in Spain, brought up the second- and third-line maniples, the *principes* and the *triarii*, on the flanks of the *hastati*. Hannibal had foreseen this manoeuvre, and countered it by bringing up the African infantry on either side of the mercenaries. But his tactical foresight was not crowned with success. The mercenaries, who were already giving ground, were routed, and the Africans with them. The reserve of Italian veterans remained intact, and Hannibal had disposed them on purpose to attack the legions if the latter should be victorious and should enter upon an undisciplined pursuit. As soon, however, as he perceived that Hannibal's third line was intact, Scipio recalled his men and re-formed them behind the natural breastwork afforded by the bodies of the casualties in the first two Carthaginian lines; having done so, he led them to the attack. Coming up from the rear at the same moment were the Italian and Numidian cavalry under Laelius and Masinissa, who had driven back the weaker Carthaginian cavalry with ease and, abandoning the pursuit in time, were returning to attack the infantry. Hannibal's veterans were thus surrounded and cut up, only very few escaping, among whom, however, was Hannibal himself (Oct. 202).

After this battle, in which, though not victorious, he had given a most wonderful exhibition of his tactical genius, Hannibal advised his fellow-citizens to make peace—indeed, almost forced them to do so—notwithstanding the very severe terms now dictated by the victor. After the conclusion of peace Carthage, despite her defeat, displayed the greatest confidence in Hannibal, and placed him at the head of the Government, thus enabling him to reorganize public affairs. Hannibal, great in administration as in war, speedily restored the State finances—to such an extent that in a short time the Carthaginians were able to make Rome an offer of payment in full of the heavy war indemnity that had been exacted. Rome, however, could not allow Carthage to recover; and so, a few years later, Roman envoys came to the city to accuse Hannibal of conspiring against the peace. He was forced to escape secretly, and took refuge (196) with Antiochus IV. the Great, king of Syria; who, having reunited the old Seleucid empire, was in diplomatic conflict with Rome, since the latter, after her victory in the Second Macedonian War, had established herself in the hegemony of the Balkan peninsula. The diplomatic conflict between Syria and Rome dragged on for some years until in the autumn of 192, in response to an appeal from the Aetolians, who had taken up arms against Rome, Antiochus landed in Greece and began the so-called Syrian War.

To this war he had been incited by the great Carthaginian refugee, who hoped that it might lead to the liberation of his country. Hannibal is said to have asked to be sent to the west with a hundred warships to prepare for a descent on Italy. This was a chimerical project, in view of the failure of the great expedition which he had so carefully prepared and ably conducted in the peninsula. It is much more likely that Hannibal simply asked Antiochus for a small land and sea force, with a view to preparing for a descent on Africa and inducing the Carthaginians to resume the war of independence against Rome and her ally Masinissa in Africa, thus causing a diversion which might also

turn greatly to the advantage of the king of Syria. But even if such were the original plans of Hannibal and Antiochus, there was no possibility of carrying them out. When the Aetolians took up arms, intervention by Antiochus in Greece became urgent and could no longer be delayed; and he was obliged to employ all his available land and sea forces in strengthening and maintaining his expeditionary forces in the peninsula. Moreover, it is obvious that, since he could not even find adequate forces in 191 to resist the attack of the Romans and Philip in Greece, he could certainly have none available for a diversion in Africa. When, defeated at Thermopylae (191), he took refuge in Asia Minor, his only thought was—inevitably—to prepare to defend by land and sea his ancestral kingdom, which the Romans were getting ready to attack.

Already in the year 191 the naval battle of the Corycus gave the Romans the command of the Aegaeon. It was essential for Antiochus to regain it in the following year. With this object, while his admiral Polyxenides was operating in the Aegaeon, Hannibal was sent to Phoenicia to collect a fleet with which to help the principal Syrian squadron. In 190 Hannibal moved north from Phoenicia with 37 warships. Near the promontory of Side he encountered the fleet of the Rhodians, allies of Rome, who disputed his passage. After a fierce fight Hannibal was defeated and forced to retire; nor did he succeed either then or later, in joining with Polyxenides to take part in the decisive struggle. By land as by sea the fortune of war was against the Syrians, and after the defeat of Polyxenides at Myonessus and that of Antiochus at Magnesia (the latter battle took place late in 190 or early in 189) the king was obliged to accept the peace terms imposed by the Romans, which included the surrender of Hannibal.

Hannibal, however, effected his escape, and after many vicissitudes—tradition gives us anecdotes of varying degrees of authenticity—we find him at the court of Prusias, king of Bithynia, one of the few despots who had not yet become dependent on Rome. It was Hannibal who suggested to his protector the magnificent site which was chosen for the foundation of the city of Prusa, the modern Brussa. Later he took part in the war between Prusias and Eumenes II., king of Pergamus, in which he gained his last success, the naval victory of the Bithynian fleet over that of Pergamus, commanded by Eumenes himself, who narrowly escaped capture. The war ended when Rome imposed her mediation on the contending parties. These events, however, drew the attention of the Romans upon Hannibal, and, through Titus Quintius Flamininus, they demanded that Prusias, who also had now been forced by circumstances to become dependent upon them, should surrender him. Prusias was cowardly enough to arrange for the great refugee's arrest; Hannibal, however, seeing his house surrounded by soldiers, committed suicide by taking poison, which he always carried on his person in readiness for emergencies (183).

The great Carthaginian had thus witnessed the complete failure of what had been the whole purpose of his life—the war of revenge by Carthage against Rome. That war had not merely ended in the defeat and destruction of the Carthaginian power, but had made Rome so conscious of her strength, and given rise to such a development of the spirit of militarism and imperialism among the Romans, that they had by now firmly established their predominance over the Eastern Greek world as well. This complete failure can in no way be laid to the charge of Hannibal, who, with unshaken patriotism, until his death employed all the resources of his genius in the unequal struggle; nor would it be fair to impute it to Carthage, whose tenacious resistance was marvellous, having regard to the forces at her command, and was at any rate immensely superior to that of the Hellenic powers, though in many respects the latter were in a much more favourable position. The failure was due to the strength of the Roman people and the Italians so firmly bound to them, to the admirable political-military organization of the Italic confederation, to the almost superhuman spirit of sacrifice exhibited by the Italians during the war, to the strategy of their leaders—the policy of attrition adopted at the beginning by Fabius when it represented

the only possibility of resistance, and the bold offensive policy later adopted by Scipio, who proved himself such a talented pupil of his great adversary as to profit by his own teaching to frustrate his most wonderful tactical inspirations.

Of the great Carthaginian's personality we know but little, and the tradition that has come down to us is often vitiated by the partisan hatred of his adversaries; but all the ancient writers without exception pay homage to his incomparable military genius, and all but a few moderns regard him as one of the greatest warriors of all time. Roman tradition charged him with acts of cruelty, and his memory lived as that of a man "abominated by the fathers" of Italy for the slaughter of their sons. But those of his cruel acts of which there is reliable evidence do not exceed what the customary laws of war in ancient times were cruel enough to permit, and the terrible tragedy of Carthage's struggle for existence affords them an extenuation which is not forthcoming for some of the atrocities committed by the Roman commanders in the second century. Moreover, on more than one occasion he displayed generosity towards a fallen enemy. The "Punic faith" of which the Roman sources accuse him seems to have no more foundation than resides in the military stratagems of which he made free use, and these were certainly far more innocent than the somewhat dishonourable stratagem employed by Scipio Africanus to surprise the camps of Hasdrubal and Syphax. For the rest, Hannibal was a cultured man, acquainted with several languages; he spoke and wrote Greek, and probably had not omitted to study the military science of the Greeks. Many of his sayings are given us by the various sources, and, though not all authentic, taken as a whole they illustrate his rough, frank, soldierly spirit. Little or nothing is known of his private life. We are told that he married a Spanish woman from Castulo, by whom he does not seem to have had any children. The ancient writers, who manage to find more or less well-authenticated scandalous anecdotes about almost all the greatest men of antiquity, laud his morality to the skies, and, much as they hate him, they can find no least speck on his fair fame in this regard. There is only one reference to be found in certain sources to a love affair with a Bruttian girl, but its authenticity is by no means sure, and it is in any case too vague to arouse our curiosity. For the rest, certain charges of avarice which we find in the ancient sources can easily be explained by his constant need of large resources for his political and military activities. Even in this matter, however, his prudent administration of the finances of Carthage bears witness to his integrity. Taken for all in all, we find him one of the noblest, as he is one of the most unfortunate, of the great men of action of antiquity.

BIBLIOGRAPHY.—The history of Hannibal was written very shortly afterwards by Greeks who were in his camp, like Sosilus and Silenus. Sosilus, as also another Greek historian of Hannibal, Chaereas, is reprimanded by Polybius (iii., 25) for his "barber's-shop anecdotes"; but a recently-discovered fragment dealing with the war in Spain (Wilcken, *Hermes*, xli., pp. 103 sqq.) does not seem to confirm the condemnation. In addition to these Greek sources, all or nearly all of which are pro-Carthaginian, the ancients had Roman primary sources, chief of which were the *Annales* of Fabius Pictor. Later a full general history of the Second Punic War was composed in Latin by L. Caelius Antipater; it is lost, but, to judge from the fragments, it was of little value. There has come down to us the Greek history of the Second Punic War composed about the middle of the second century B.C. by the Greek historian Polybius of Megalopolis; it is complete as far as the battle of Cannae (lib. iii.), fragmentary thereafter. Polybius combined Carthaginian and Roman sources—in what proportions it is difficult to say, but it is certainly a mistake to suppose that our tradition regarding the Second Punic War is wholly of Roman origin (Dessau, *Hermes*, li., pp. 355 sqq.), or to try to make a mechanical separation of the Roman and Carthaginian passages in the text of Polybius (Beloch, *Hermes*, l.). The full story of the Second Punic War has come down to us in the third decade of Livy; and here again, while we have passages of undoubted annalistic origin and others, particularly dealing with the wars in Sicily and the East, that are mere versions of Polybius, regarding the remainder there are strong differences of opinion among the critics. Of the copious bibliography mention need only be made of Wesselbarth's *Historisch-kritische Untersuchungen zur dritten Dekade des Livius*, and for the rest the student may be referred to the historical works cited below. Of the minor sources, apart from those derived from Livy (Florus, Orosius, etc.), we need only mention here Plutarch's lives of Fabius and Marcellus, Appian's *Hannibalic*, and the

fragments of Diodorus and Dion Cassius, all of which narrations appear to be based on the vulgate of Polybius, with additions and errors in varying degrees.

The modern Hannibalic bibliography is enormous. On a single episode in his career—the crossing of the Alps—a whole shelf of monographs could be collected; and no year passes without publications on this subject in various languages, especially English. Neglecting entirely the earlier writings and those that deal with too specialized subjects, we may mention in the first place Mommsen's passage on Hannibal and his wars (*Röm. Geschichte*, vol. i., book iii.), and Neumann's *Das Zeitalter der punischen Kriege* (Breslau, 1883), a solid and well-balanced treatise. Acute and original, though frequently hypercritical, is U. Kahrstedt, *Geschichte der Karthager von 218–146* (Berlin, 1919; published as vol. iii. of O. Meltzer's *Geschichte der Karthager*, but entirely different in character from the first two volumes). This work contains an exhaustive discussion of the sources. On the military aspect two works are of fundamental importance, though frequently at variance with each other: these are Delbrück's *Geschichte der Kriegskunst* (2nd ed., Berlin, 1908), book v., and Kromayer's *Antike Schlachtfelder*, iii., 1. Italien and 2. Afrika (Berlin, 1912); in addition, K. Lehmann, *Die Angriffe der drei Barkiden auf Italien* (Leipzig, 1905), may be read with profit. An attempt at a comprehensive political and military appreciation of the history of the Second Punic War, its antecedents and its consequences, is made in De Sanctis, *Storia dei Romani*, especially in vol. iii. 2 (Turin, 1917). For the most recent bibliography reference may be made to the text accompanying Kromayer and Veith's *Schlachten-Atlas*, Röm. Abteilung, Liefg. i and ii. (Leipzig, 1922). Lastly, special mention must be made of the *Untersuchungen zur Geschichte des zweiten punischen Krieges* collected by E. Meyer in his *Kleine Schriften*, ii. (Halle, 1924), and his drawings of medallions of Hannibal and Scipio in *Meister der Politik* (I. 2nd ed., 1923). (G. DE S.)

HANNIBAL, a city of Marion county, Mo., U.S.A., on the Mississippi river, 120m. above Saint Louis. It is on Federal highways 36 and 61, and is served by the Burlington, the St. Louis and Hannibal and the Wabash railways, and by river steamers and barges. The population was 19,306 in 1920 (9.3% negroes), and was estimated locally at over 21,000 in 1928. Behind the low, level business section of the city rise picturesque bluffs and hills to a height of 200ft. above the river, on which are most of the residences. Riverview park (200ac.) affords magnificent views of the Mississippi valley. The Burlington has large repair shops here, and there are numerous and varied factories, with an output in 1925 valued at \$15,852,479. Mark Twain spent his boyhood in Hannibal, which provided the setting of his *Life on the Mississippi*, *Huckleberry Finn*, and *Tom Sawyer*. His home at 316 Hill street, a two-story frame house built by his father John Marshall Clemens in 1844, is maintained by the city as a memorial. A statue of him stands on an eminence in Riverview park, looking out over the river, and there is one of Huck Finn and Tom Sawyer at the foot of Cardiff hill. The cave described in *Tom Sawyer*, 2m. S. of the city, extending south-eastwardly to the Salt river, 9m. away, was used as a hiding-place for slaves escaping by the "Underground Railway," and twice was a refuge for Jesse James. The site of Hannibal was part of old Spanish grants, and this gave rise to much litigation in the early days. The name Hannibal was given by a Spanish surveyor to the small stream (now called Bear creek) which empties into the Mississippi at this point, and was transferred to the settlement. The first settler, Moses D. Bates, arrived in 1818. The town was laid out in 1819 and chartered as a city in 1839.

HANNINGTON, JAMES (1847–1885), English missionary, was born at Hurstpierpoint, Sussex, on Sept. 3, 1847, and was educated at St. Mary's Hall, Oxford. He was curate in charge at Hurstpierpoint when his thoughts were turned to mission work by the murder of two missionaries on the shores of Victoria Nyanza. He sailed on May 17, 1882, at the head of a party of six, for Zanzibar, and thence set out for Uganda; but, prostrated by fever and dysentery, he was obliged to return to England in 1883. On his recovery he was consecrated bishop of Eastern Equatorial Africa (June 1884), and in January 1885 started again for the scene of his mission, and visited Palestine on the way. He reached a spot near Victoria Nyanza in safety. His arrival, however, roused the suspicion of the natives, and under King Mwanga's orders he was lodged in a filthy hut swarming with rats and vermin. After eight days his men were murdered, and on Oct. 29, 1885 he himself was speared in both sides, his last words to the soldiers appointed to kill him being, "Go, tell Mwanga I

have purchased the road to Uganda with my blood."

His *Last Journals* were edited in 1888. See also *Life* by E. C. Dawson (1887); and W. G. Berry, *Bishop Hannington* (1908).

HANNINGTON, a shallow lake (7 m. by 2 m.) in Kenya Colony, south of Lake Baringo, just south of the Equator. It lies in the eastern rift-valley, in the shadow of the Laikipia escarpment. It was named after Bishop Hannington; its waters are brackish, its shores having on them remnants of an ancient forest which serve as an eyrie for storks, herons and eagles, whilst on the flat banks congregate thousands of flamingoes. There are valuable guano deposits here.

HANNO, the name of many Carthaginian soldiers and statesmen, the most important of whom are:

1. **HANNO**, Carthaginian navigator, who flourished c. 500 B.C. He wrote an account of a coasting voyage on the west coast of Africa, undertaken for the purpose of exploration and colonization. The original, inscribed on a tablet in the Phoenician language, was hung up in the temple of Melkarth on his return to Carthage. A supposed Greek translation of this is still extant, under the title of *Periplus*, but its authenticity has been questioned. Hanno appears to have advanced beyond Sierra Leone as far as Cape Palmas.

Valuable editions by T. Falconer (1797, with translation and notes) and C. W. Müller in *Geographici Graeci minores*, i.; see also E. H. Bunbury, *History of Ancient Geography*, i. and treatise by C. T. Fischer (1893), with bibliography.

2. **HANNO** (3rd century B.C.), called "the Great," Carthaginian statesman and general, leader of the aristocratic party and the chief opponent of Hamilcar and Hannibal. He appears to have gained his title from military successes in Africa, but of these nothing is known. In 240 B.C. he drove Hamilcar's veteran mercenaries to rebellion by withholding their pay, and when invested with the command against them was so unsuccessful that Carthage might have been lost but for the exertions of Hamilcar (q.v.). Hanno subsequently remained at Carthage, exerting his influence against the democratic party. During the Second Punic War he advocated peace with Rome, and according to Livy even advised that Hannibal should be given up to the Romans. After the battle of Zama (202) he was one of the ambassadors sent to Scipio to sue for peace.

Livy xxi. 3 ff., xxiii. 12; Polybius i. 67 ff.; Appian, *Res Hispanicae*, 4, 5, *Res Punicae*, 34, 49 68.

For others of the name see **CARTHAGE**; **HANNIBAL**; **PUNIC WARS** and Smith's *Classical Dictionary*.

HANOI, capital of Tongking and of French Indo-China, on the right bank of one of the mouths of the delta of the Song-koi or Red river, about 80 m. from its mouth in the Gulf of Tongking. Pop. 140,000. The town consists of a European quarter and a crowded native quarter built round a picturesque lake which lies close to the river. The so-called pagoda of the Great Buddha is the chief native building. The river is embanked and is crossed by the Pont Doumer, a fine railway bridge over 1 m. long. Vessels drawing 8 or 9 ft. can reach the town. Hanoi is the seat of the general government of Indo-China, of the resident-superior of Tongking, and of a bishop, who is vicar-apostolic of central Tongking. It is administered by an elective municipal council with a civil service administrator as mayor. It has a chamber of commerce, a chamber of the court of appeal of Indo-China, a civil tribunal of the first order, and is the seat of the chamber of agriculture of Tongking. Its industries include cotton-spinning, brewing, distilling and the manufacture of tobacco, earthenware and matches; native industry produces carved and inlaid furniture, bronzes and artistic metalwork, silk embroidery, etc. Hanoi is the junction of railways to Hai-Phong, its seaport, Lao-Kay, Vinh, and the Chinese frontier via Lang-Son. It is in frequent communication with Hai-Phong by steamboat.

See C. Madrolle, *Tonkin du sud: Hanoi* (1907).

HANOTAUX, ALBERT AUGUSTE GABRIEL (1853–), French statesman and historian, was born at Beaurevoir, Aisne, on Nov. 19, 1853. He studied at the École des Chartes, and became *maître de conférences* in the École des Hautes Études. In 1879 he entered the ministry of foreign affairs as archivist, and rose step by step through the diplomatic service, being appointed

councillor of embassy at Constantinople in 1885. In 1886 he was elected Republican deputy for Aisne, but, defeated in 1889, he returned to his diplomatic career. On May 31, 1894 he became foreign minister in the Dupuy cabinet. With one interruption (during the Ribot ministry, Jan. 26–Nov. 2, 1895), he held this portfolio until June 14, 1898. During his ministry he developed the *rapprochement* of France with Russia, visiting St. Petersburg with the President, Félix Faure, and sent expeditions to delimit the French colonies in Africa. The Fashoda incident of July 1898 was a result of this policy, and Hanotiaux's distrust of England is frankly stated in his literary works.

During the World War Hanotiaux, who was already known as a distinguished historian, and had been elected to the French Academy on April 1, 1897, was active as propagandist. He was employed on more than one semi-official mission, notably to the Vatican. In 1921 he was the third French delegate to the League of Nations Assembly.

Hanotiaux's works include: *Origines de l'institution des intendants de provinces* (1884), the authoritative study on the intendants; *Études historiques sur les XVI^e et XVII^e siècles en France* (1886); *Histoire de Richelieu* (2 vols. 1888); *Histoire de la France contemporaine, 1871–1900* (4 vols. 1903–8), the standard history of contemporary France; *Histoire de la Guerre de 1914* (9 vols. 1914 ff.); *Le Traité de Versailles* (1919); *Histoire de la Nation française* (15 vols. 1920–4); *La Bataille de la Marne* (2 vols. 1923). He also edited the *Instructions des ambassadeurs de France à Rome, depuis les traités de Westphalie* (1888).

HANOVER, formerly an independent kingdom of Germany, but since 1866 a province of Prussia, bounded on the north by the North Sea, Schleswig-Holstein, Hamburg and Mecklenburg-Schwerin, east and south-east by Prussian Saxony, Brandenburg and Brunswick, south-west by Lippe and the Prussian provinces of Hesse-Nassau and Westphalia, and west by Holland. These boundaries include the republic of Oldenburg and the free state of Bremen, the former stretching southward from the North Sea nearly to the southern boundary of Hanover. A small part of the province in the south is separated from Hanover proper by the interposition of part of Brunswick. In 1873 the province was increased by the addition of the Jade territory (purchased by Prussia from Oldenburg), south-west of the Elbe, with the naval station and arsenal of Wilhelmshaven. The area of the province is 14,897 sq. miles.

The plain of Hanover is mainly sandhills, heath and moor. On the Elbe and near the North Sea, rich meadows are preserved from encroachment of the sea by dikes and ditches. The so-called *Lüneburger Heide* in the north is an expanse of moor and fen, with oases of beech and oak woods, extending almost due north from the city of Hanover to the southern arm of the Elbe at Harburg. The south part of the province is hilly, rising to the forested Harz mountains. The east part of the northern plain is covered with fir forests. The Elbe forms the north-east boundary and receives the navigable Jeetze, Ilmenau, Lühe, Seve, Este, Schwinge and Medem; the Weser drains the centre, with its tributary the Aller (navigable from Celle downwards); and the Ems, the west, with its tributaries Aa and Leda. Numerous canals connect these river systems. A few small lakes are found here and there in the province.

The climate in the coastal lowlands is moist and foggy, in the plains mild, on the Harz mountains severe and variable. In spring the prevailing winds are easterly, in summer they blow from the south-west. In the town of Hanover the average monthly temperature ranges from 32° F in January to 63° F in July, and the average annual rainfall is about 23.5 in. In the west the Herauch, a thick fog arising from the burning of the moors, is of frequent occurrence.

The population in 1925 was 3,190,619, giving a density of 214 to the sq.m. (English). The province is divided into the six *Regierungsbezirke* (or departments) of Hanover, Hildesheim, Lüneburg, Stade, Osnabrück and Aurich, and these again into *Kreise* (circles, or local government districts)—82 in all. The chief towns are Hanover, Osnabrück, Hildesheim, Wesermünde, Wilhelmshaven, Harburg, Lüneburg, Celle, Göttingen and Emden. Above 80% of the population are Protestant. A court of appeal for the province sits at Celle.

The province has the university of Göttingen, a technical college in Hanover, an academy of forestry in Münden, a mining college in Clausthal, and a veterinary college in Hanover.

The greater part of the soil is of inferior quality, and one-third of the province is uncultivated moor and heath; about half the remainder is arable and the rest pasture and forest. The best agriculture is to be found in the districts of Hildesheim, Calenberg, Göttingen and Grubenhagen, on the banks of the Weser and Elbe, and in East Friesland. Rye is widely grown for bread. Flax is extensively cultivated and exported, chiefly in the form of yarn. Potatoes, hemp, turnips, hops, tobacco and beets are also grown, the latter in connection with the sugar industry. Apples, pears, plums and cherries are the principal fruits cultivated, while the wild red cranberries from the Harz and the black bilberries from the Lüneburger Heide form an important article of export.

Hanover is renowned for its cattle and live stock. The Lüneburger Heide yields excellent sheep, while horses are reared in Aurich and Stade, in Hildesheim, Hanover and in Celle. Bees are principally kept on the Lüneburger Heide, and the yield of honey is considerable. Large flocks of geese are kept in the moist lowlands. The rivers yield trout, salmon (in the Weser) and crayfish. The sea fisheries are important and have their chief centre at Wesermünde.

The Harz mountains are rich in silver, lead, iron and copper; coal is found around Osnabrück, on the Deister, at Osterwald, etc., lignite in various places; salt-springs exist at Egestorfshall and Neuhaus near Hanover, and at Lüneburg; and petroleum is obtained south of Celle. In the cold regions of the northern lowlands peat occurs.

Works for the manufacture of iron, copper, silver, lead, vitriol and sulphur are carried on. The iron works are important: smelting is carried on in the Harz and near Osnabrück; there are extensive foundries and machine factories at Hanover, Linden, Osnabrück, Hameln, Wesermünde, Harburg, Osterode, etc., and manufactories of cutlery in the towns of the Harz and in the Sollinger Forest. Linen yarn and cloth are largely manufactured, and bleaching is engaged in extensively; woollen cloths are made in the south about Einbeck, Göttingen and Hameln; cotton-spinning and weaving have their seats at Hanover and Linden. Glass houses, paper-mills, potteries, tile works and tobacco-pipe works are numerous. There are numerous tobacco factories, tanneries, breweries, vinegar works and brandy distilleries. Ship-building is an important industry, especially at Wilhelmshaven, Papenburg, Leer, Stade and Harburg; and at Münden river-barges are built.

The carrying trade of Hanover is largely absorbed by Hamburg and Bremen, while the Weser forms the chief commercial artery of the province. The province has good roads connecting the chief towns and is intersected by trunk lines of railway; notably the lines from Berlin to Cologne, from Hamburg to Frankfurt-on-Main, from Hamburg to Bremen and Cologne, and from Berlin to Amsterdam.

HISTORY

The name Hanover (*Hohenufer*=high bank), originally confined to the town which became the capital of the duchy of Lüneburg-Calenberg, came gradually into use to designate, first, the duchy itself, and secondly, the electorate of Brunswick-Lüneburg; and it was officially recognized as the name of the state when in 1814 the electorate was raised to the rank of a kingdom.

The early history of Hanover is merged in that of the duchy of Brunswick (*q.v.*), from which the duchy of Brunswick-Lüneburg and its offshoots, the duchies of Lüneburg-Celle and Lüneburg-Calenberg, have sprung. In 1692, in return for lavish promises of assistance to the empire and the Habsburgs, the emperor granted Duke Ernest Augustus of Calenberg the rank and title of elector of Brunswick-Lüneburg with the office of standard bearer in the Holy Roman empire. Indignant protests followed, but in 1708 George Louis, the son and successor of Ernest Augustus, was recognized as an elector by the imperial diet. Through his mother, the elector George Louis became, by the terms of the Act of

Settlement of 1701, king of Great Britain and Ireland in 1714.

Under British Sovereignty.—From this time until the death of William IV. in 1837, Lüneburg or Hanover, was ruled by the same sovereign as Great Britain. Both George I. and George II. preferred Hanover to England as a place of residence, and it was a frequent and perhaps justifiable cause of complaint that the interests of Great Britain were sacrificed to those of the smaller country. But George III. was more British than either his grandfather or his great-grandfather, and owing to a variety of causes the foreign policies of the two countries began to diverge in the later years of his reign. During the Napoleonic wars Hanover was occupied by Prussia in 1805, but after the battle of Jena (1807) became part of the kingdom of Westphalia. The northern portion was added to France in 1810. The elector was granted the title of king by the Vienna Congress, which restored the independence of Hanover. On the conclusion of peace in 1814 the estates of the several provinces of the kingdom were fused into one body, consisting of 85 members, but the chief power was exercised as before by the members of a few noble families. In 1819, however, this feudal relic was supplanted by a new constitution. Two chambers were established, the one formed of nobles and the other of elected representatives; but although they were authorized to control the finances, their power with regard to legislation was very circumscribed. This constitution was sanctioned by the prince regent, afterwards King George IV.; but it was out of harmony with the new and liberal ideas which prevailed in Europe, and it hardly survived George's decease in 1830. The revolution of that year compelled George's brother and successor, William, to dismiss Count Münster, who had been the actual ruler of the country, and to name his own brother, Adolphus Frederick, duke of Cambridge, a viceroy of Hanover, one of the viceroy's earliest duties being to appoint a commission to draw up a new constitution. This was done, and after William had insisted upon certain alterations, it was accepted and promulgated in 1833. Representation was granted to the peasants; the two chambers were empowered to initiate legislation; ministers were made responsible for all acts of government; a civil list was given to the king in return for the surrender of the Crown lands; and, in short, the new constitution was similar to that of Great Britain.

King Ernest Augustus.—By the law of Hanover a woman could not ascend the throne, and accordingly Ernest Augustus, duke of Cumberland, the fifth son of George III., and not Victoria, succeeded William as sovereign in 1837, thus separating the crowns of Great Britain and Hanover after a union of 123 years. Ernest, a prince with very autocratic ideas, had disapproved of the constitution of 1833, and his first important act as king was to declare it invalid. He appears to have been especially chagrined because the Crown lands were not his personal property, but the new arrangements were quite repugnant to him. Seven Göttingen professors who protested against this proceeding were deprived of their chairs; and some of them, including F. C. Dahlmann and Jakob Grimm, were banished from the country for publishing their protest. To save the constitution an appeal was made to the German Confederation, which Hanover had joined in 1815; but the federal diet declined to interfere, and in 1840 Ernest altered the constitution to suit his own illiberal views. Recovering the Crown lands, he abolished the principle of ministerial responsibility, the legislative power of the two chambers, and other reforms, virtually restoring affairs to their condition before 1833. The inevitable crisis was delayed until the stormy year 1848, when the king probably saved his crown by hastily giving back the constitution of 1833. Order, however, having been restored in 1850 he dismissed the Liberal ministry and attempted to evade his concessions; a bitter struggle had just broken out when Ernest Augustus died in Nov. 1851. During this reign the foreign policy of Hanover both within and without Germany had been coloured by jealousy of Prussia and by the king's autocratic ideas. Refusing to join the Prussian *Zollverein*, Hanover had become a member of the rival commercial union, the *Steuerverein*, three years before Ernest's accession; but as this union was not a great success the *Zollverein* (*q.v.*) was joined in 1851. In 1849, after the

failure of the German parliament at Frankfort, the king had joined with the sovereigns of Prussia and Saxony to form the "three kings' alliance"; but this union with Prussia was unreal, and with the king of Saxony he soon transferred his support to Austria and became a member of the "four kings' alliance."

Annexation to Prussia.—George V., the new king of Hanover, who was unfortunately blind, sharing his father's political ideas, at once appointed a ministry whose aim was to sweep away the constitution of 1848. This project, however, was resisted by the second chamber of the *Landtag*, or parliament; and after several changes of government a new ministry advised the king in 1855 to appeal to the diet of the German Confederation. This was done, and the diet declared the constitution of 1848 to be invalid. Acting on this verdict, not only was a ministry formed to restore the constitution of 1840, but after some trouble a body of members fully in sympathy with this object was returned to parliament in 1857. But these members were so far from representing the opinions of the people that popular resentment compelled George to dismiss his advisers in 1862, and the more liberal government which succeeded did not enjoy his complete confidence. In 1865 a ministry was once more formed which was more in accord with his own ideas. This contest soon lost both interest and importance owing to the condition of affairs in Germany. Bismarck, the director of the policy of Prussia, was devising methods for the realization of his schemes, and it became clear after the war over the duchies of Schleswig and Holstein that the smaller German states would soon be obliged to decide definitely between Austria and Prussia. After a period of vacillation Hanover threw in her lot with Austria, the decisive step being taken when the question of the mobilization of the federal army was voted upon in the diet on June 14, 1866. At once Prussia requested Hanover to remain unarmed and neutral during the war, and with equal promptness King George refused to assent to these demands. Prussian troops then crossed his frontier and took possession of his capital. The Hanoverians, however, were victorious at the battle of Langensalza on June 27, 1866, but the advance of fresh bodies of the enemy compelled them to capitulate two days later. By the terms of this surrender the king was not to reside in Hanover, his officers were to take no further part in the war, and his ammunition and stores became the property of Prussia. The decree of Sept. 20, 1866, formally annexed Hanover to Prussia, when it became a province of that kingdom, while King George from his retreat at Hietzing appealed in vain to the powers of Europe. For some years many of the Hanoverians remained loyal to their sovereign, some of them serving in the Guelph Legion, which was maintained largely at his expense in France, where a paper, *La Situation*, was founded by Oskar Meding (1829-1903) and conducted in his interests.

HANOVER, capital of the Prussian province of the same name, situated in a sandy, fertile plain on the Leine, which here receives the Ihme, and at the crossing of the main lines of railway, Berlin to Cologne and Hamburg to Frankfort-on-Main. Pop., including Linden (1925), 422,708. The town of Hanover is first mentioned during the 12th century, when it belonged to the family of Wolf, who became dukes of Brunswick. It joined the Hanseatic League, and was later the residence of the electors of Hanover. In 1866 it was annexed by Prussia, after having been the capital of the kingdom of Hanover since its foundation in 1815. The Leine flows through the city, having the old town, with narrow streets and old-fashioned gabled houses, on its right. In its centre lies the Markt Kirche, a red-brick edifice of the

14th century, with its interior restored in 1855, and containing fine stained-glass windows. On the market square, is the red-brick mediaeval town hall (Rathaus), containing the civic archives and museum. The new town surrounds the old on the north and east. Among the other churches are the Neustädterkirche, with a shrine containing the tomb of Leibnitz; the Kreuzkirche, built about 1300, with a curious steeple; and the Aegidienkirche. Of secular buildings the most remarkable is the royal palace—Schloss—built 1636-40. In its chapel are preserved the relics of saints which Henry the Lion brought from Palestine. Its museums have important art collections. The Welfenschloss has been occupied since 1875 by the technical high school, an academy with university privileges. Close to it lies Herrenhausen, the summer palace of the former kings of Hanover, with fine gardens, an open-air theatre, a museum and an orangery, and approached by a grand avenue over a mile in length.

Hanover's railway connections have enormously developed its trade and manufactures. Almost all industries are represented; chief among them are machine-building, the manufacture of india-rubber, cotton, cork, hardware, chemicals, cocoa, asphalt, tobacco, pianos, furniture and groceries. The commerce consists principally in wine, hides, horses, coal, wood and cereals. There are extensive printing establishments. It is the birthplace of Sir William Herschel, the astronomer, and the philosopher Leibnitz died there in 1716.

HANOVER, a town of Jefferson county, Ind., U.S.A., on the Ohio river, 5m. below Madison, the nearest railway station. The population was 360 in 1920. At the edge of the town, on a bluff 500ft. above the river, is Hanover college (Presbyterian), opened in a log cabin in 1827 as an academy, and incorporated as a college in 1833. Its theological department was established as a separate institution and moved to New Albany in 1840, and thence in 1859 to Chicago, becoming (1886) the McCormick Theological seminary.

HANOVER, a borough of York county, Pa., U.S.A., in the fertile Conewago valley, 36m. S. by W. of Harrisburg and 6m. from the southern boundary of the State. It is at the intersection of several old turnpikes, and is served by the Pennsylvania and the Western Maryland railways. The population was 8,664 in 1920 (98% native white) and was estimated locally at 15,000 in 1928. It is the trading point for a rich farming region, and is also a busy industrial centre, with 111 plants, producing a great variety of goods, valued at \$17,000,000 annually. Hanover was laid out in 1763 or 1764, by Col. Richard MacAllister, and was incorporated as a borough in 1815. The first settlers were largely Germans, and it was named after the German city. On June 30, 1863, a cavalry engagement was fought in the vicinity, preliminary to the battle of Gettysburg, between the forces of Gen. H. J. Kilpatrick (Union) and Gen. J. E. B. Stuart (Confederate).

HANRIOT, FRANÇOIS (1761-1794), French revolutionist, was born at Nanterre (Seine) of poor parentage. He became one of the orators of the *sans-culottes*, and commanded the armed force of that section during the insurrection on Aug. 10, 1792 and the massacres of September. He was appointed by the Commune to the command of the armed forces of Paris on May 30-31, from June 2 to June 11, and again after the failure of his impeachment in the Convention, from July 1 until the revolution of the 9th Thermidor (July 27, 1794). He was then arrested, after a vain attempt to rescue Robespierre, and was guillotined with Robespierre and his friends on the 10th Thermidor of the year II. (July 28, 1794).

HANSARD, LUKE (1752-1828), English printer, was born in St. Mary's parish, Norwich, educated at Boston grammar school, and apprenticed to Stephen White, a Norwich printer. As soon as his apprenticeship had expired Hansard started for London with only a guinea in his pocket, and became a compositor in the office of John Hughs (1703-71), printer to the House of Commons. In 1774 he was made a partner, and in 1800 the business came completely into his hands. He printed the *Journals of the House of Commons* from 1774 till his death. The promptitude and accuracy with which he printed parliamentary papers were often of the greatest service to the Government—notably on one occa-

sion when the proof-sheets of the report of the Secret Committee on the French Revolution were submitted to Pitt 24 hours after the draft had left his hands. He devised numerous expedients for reducing the expense of publishing the reports; and in 1805, when his workmen struck at a time of great pressure, he and his sons themselves set to work as compositors. Luke Hansard died on Oct. 29, 1828.

His son, THOMAS CURSON HANSARD (1776-1833), established a press of his own in Paternoster Row, and began in 1803 to print the *Parliamentary Debates*, which were not at first independent reports, but were taken from the newspapers. After 1889 the debates were published by the Hansard Publishing Union Limited. The original business remained in the hands of his younger brothers, James and Luke Graves Hansard (1777-1851). The firm was prosecuted in 1837 by John Joseph Stockwell for printing by order of the House of Commons, in an official report of the inspector of prisons, statements regarded by the plaintiff as libellous. Hansard sheltered himself on the ground of privilege, but it was not until after much litigation that the security of the printers of Government reports was guaranteed by statute in 1840.

HANS DER BÜHELER (HANS VON BUHEL), German poet of the 15th century, was born probably in Buhl, near Rastatt. While in the service of the archbishop of Cologne, he wrote two narrative poems. The first, *Die Königstochter von Frankreich* (1400, ed. Merzdorf, 1867), was based on a 13th century poem, *Mai und Beaffor*; the second, *Diocletians Leben* (1412, ed. Keller, 1841), relates the story of the seven white masters.

See G. Seelig in "*Strasburger Studien*," vol. iii. (1888); K. Büschagens, *Hans von Bühel* (1921); Wellen, *Über den Stil der "Königstochter von Frankreich"* (1921).

HANSEATIC LEAGUE. It is impossible to assign any precise date for the beginning of the Hanseatic League or to name any single factor which explains the origin of that loose but effective federation of north German towns. Associated action and partial union among these towns can be traced back to the 13th century. In 1241 we find Lübeck and Hamburg agreeing to safeguard the important road connecting the Baltic and the North sea. The first known meeting of the "maritime towns," later known as the Wendish group and including Lübeck, Hamburg, Lüneburg, Wismar, Rostock and Stralsund, took place in 1256. The Saxon towns, during the following century, were joining to protect their common interests, and indeed at this period town confederacies in Germany, both north and south, were so considerable as to call for declaration against them in the Golden Bull of 1356. The decline of the imperial power and the growing opposition between the towns and the territorial princes justified these defensive town alliances, which in south Germany took on a peculiarly political character. The relative weakness of territorial power in the north, after the fall of Henry the Lion of Saxony, diminished without however removing this motive for union, but the comparative immunity from princely aggression on land left the towns more free to combine in a stronger and more permanent union for the defence of their commerce by sea and for the control of the Baltic.

While the political element in the development of the Hanseatic League must not be underestimated, it was not so formative as the economic. The foundation was laid for the growth of German towns along the southern shore of the Baltic by the great movement of German colonization of Slavic territory east of the Elbe. This movement, extending in time from about the middle of the 11th to the middle of the 13th century and carrying a stream of settlers and traders from the north-west, resulted not only in the Germanization of a wide territory but in the extension of German influence along the sea-coast far to the east of actual territorial settlement. The German trading towns, at the mouths of the numerous streams which drain the north European plain, were stimulated or created by the unifying impulse of a common and long-continued advance of conquest and colonization.

The impetus of this remarkable movement of expansion not only carried German trade to the east and north within the Baltic basin, but reanimated the older trade from the lower Rhine region to Flanders and England in the west. Cologne and the West-

phalian towns, the most important of which were Dortmund, Soest and Münster, had long controlled this commerce but now began to feel the competition of the active traders of the Baltic, opening up that direct communication by sea from the Baltic to western Europe which became the essential feature in the history of the League. The necessity of seeking protection from the sea-rovers and pirates who infested these waters during the whole period of Hanseatic supremacy, the legal customs, substantially alike in the towns of north Germany, which governed the groups of traders in the outlying trading posts, the establishment of common factories, or "counters" (Komtoren) at these points, with aldermen to administer justice and to secure trading privileges for the community of German merchants—such were some of the unifying influences which preceded the gradual formation of the League. In the century of energetic commercial development before 1350 the German merchants abroad led the way.

The Gothland Association.—Germans were early pushing as permanent settlers into the Scandinavian towns, and in Wisby, on the island of Gothland, the Scandinavian centre of Baltic trade, equal rights as citizens in the town government were possessed by the German settlers as early as the beginning of the 13th century. There also came into existence at Wisby the first association of German traders abroad, which united the merchants of over 30 towns, from Cologne and Utrecht in the west to Reval in the east. We find the Gothland association making in 1229 a treaty with a Russian prince and securing privileges for their branch trading station at Novgorod. According to the "Skra," the by-laws of the Novgorod branch, the four aldermen of the community of Germans, who among other duties held the keys of the common chest, deposited in Wisby, were to be chosen from the merchants of the Gothland association and of the towns of Lübeck, Soest and Dortmund. The Gothland association received in 1237 trading rights in England, and shortly after the middle of the century it also secured privileges in Flanders. It legislated on matters relating to common trade interests, and, in the case of the regulation of 1287 concerning shipwrecked goods, we find it imposing this legislation on the towns under the penalty of exclusion from the association. But with the extension of the east and west trade beyond the confines of the Baltic, this association by the end of the century was losing its position of leadership. Its inheritance passed to the gradually forming union of towns, chiefly those known as Wendish, which looked to Lübeck as their head. In 1293 the Saxon and Wendish merchants at Rostock decided that all appeals from Novgorod be taken to Lübeck instead of to Wisby, and six years later the Wendish and Westphalian towns, meeting at Lübeck, ordered that the Gothland association should no longer use a common seal. Though Lübeck's right as court of appeal from the Hanseatic counter at Novgorod was not recognized by the general assembly of the League until 1373, the long-existing practice had simply accorded with the actual shifting of commercial power. The union of merchants abroad was beginning to come under the control of the partial union of towns at home.

A similar and contemporary extension of the influence of the Baltic traders under Lübeck's leadership may be witnessed in the west. As a consequence of the close commercial relations early existing between England and the Rhenish-Westphalian towns, the merchants of Cologne were the first to possess a gild-hall in London and to form a "hansa" with the right of admitting other German merchants on payment of a fee. The charter of 1226, however, by which Emperor Frederick II. created Lübeck a free imperial city, expressly declared that Lübeck citizens trading in England should be free from the dues imposed by the merchants of Cologne and should enjoy equal rights and privileges. In 1266 and 1267 the merchants of Hamburg and Lübeck received from Henry III. the right to establish their own hansas in London, like that of Cologne. The situation thus created led by 1282 to the coalescence of the rival associations in the "Gild-hall of the Germans," but though the Baltic traders had secured a recognized foothold in the enlarged and unified organization, Cologne retained the controlling interest in the London settlement until 1476. Lübeck and Hamburg, however, dominated the German trade in the ports of the east coast, notably in Lynn and Boston,

while they were strong in the organized trading settlements at York, Hull, Ipswich, Norwich, Yarmouth and Bristol. The counter at London, first called the Steelyard in a parliamentary petition of 1422, claimed jurisdiction over the other factories in England.

The Counter of Bruges.—In Flanders, also, the German merchants from the west had long been trading, but here had later to endure not only the rivalry but the pre-eminence of those from the east. In 1252 the first treaty privileges for German trade in Flanders show two men of Lübeck and Hamburg heading the "Merchants of the Roman Empire," and in the later organization of the counter at Bruges four or five of the six aldermen were chosen from towns east of the Elbe, with Lübeck steadily predominant. The Germans recognized the staple rights of Bruges for a number of commodities, such as wool, wax, furs, copper and grain, and in return for this material contribution to the growing commercial importance of the town, they received in 1309 freedom from the compulsory brokerage which Bruges imposed on foreign merchants. The importance and independence of the German trading settlements abroad were exemplified in the statutes of the "Company of German merchants at Bruges," drawn up in 1347, where for the first time appears the grouping of towns in three sections (the "Drittelle"), the Wendish-Saxon, the Prussian-Westphalian and those of Gothland and Livland. Even more important than the assistance which the concentration of the German trade at Bruges gave to that leading mart of European commerce was the service rendered by the German counter of Bruges to the cause of Hanseatic unity. Not merely because of its central commercial position, but because of its width of view, its political insight and its constant insistence on the necessity of union, this counter played a leading part in Hanseatic policy. It was more Hanse than the Hanse towns.

The last of the chief trading settlements, both in importance and in date of organization, was that at Bergen in Norway, where in 1343 the Hanseatics obtained special trade privileges. Scandinavia had early been sought for its copper and iron, its forest products and its valuable fisheries, especially of herring at Schonen, but it was backward in its industrial development and its own commerce had seriously declined in the 14th century. It had come to depend largely upon the Germans for the importation of all its luxuries and of many of its necessities, as well as for the exportation of its products, but regular trade with the three kingdoms was confined for the most part to the Wendish towns, with Lübeck steadily asserting an exclusive ascendancy. The fishing centre at Schonen was important as a market, though, like Novgorod, its trade was seasonal, but it did not acquire the position of a regularly organized counter, reserved alone, in the north, for Bergen. The commercial relations with the north cannot be regarded as an important element in the union of the Hanse towns, but the geographical position of the Scandinavian countries, especially that of Denmark, commanding the Sound which gives access to the Baltic, compelled a close attention to Scandinavian politics on the part of Lübeck and the League and thus by necessitating combined political action in defence of Hanseatic sea-power exercised a unifying influence.

Energetic and successful though the scattered trading settlements had been in establishing German trade connections and in securing valuable trade privileges, the middle of the 14th century found them powerless to meet difficulties arising from internal dissension and still more from the political rivalries and trade jealousies of nascent nationalities. Flanders became a battle-field in the great struggle between France and England, and the war of trade prohibitions led to infractions of the German privileges in Bruges. An embargo on trade with Flanders, voted in 1358 by a general assembly, resulted by 1360 in the full restoration of German privileges in Flanders, but reduced the counter at Bruges to an executive organ of a united town policy. It is worth noting that in a document connected with this action the union of towns, borrowing the term from English usage, was first called the "German Hansa." In 1361 representatives from Lübeck and Wisby visited Novgorod to recodify the by-laws of the counter and to admonish it that new statutes required the consent of Lübeck, Wisby, Riga, Dorpat and Reval. This action was confirmed in

1366 by an assembly of the Hansa which at the same time, on the occasion of a regulation made by the Bruges counter and of statutes drawn up by the young Bergen counter, ordered that in future the approval of the towns must be obtained for all new regulations.

Hanseatics in England.—The counter at London was soon forced to follow the example of the other counters at Bruges, Novgorod and Bergen. After the failure of the Italians, the Hanseatics remained the strongest group of alien merchants in England, and, as such, claimed the exclusive enjoyment of the privileges granted by the *Carta Mercatoria* of 1303. Their highly favoured position in England, contrasting markedly with their refusal of trade facilities to the English in some of the Baltic towns and their evident policy of monopoly in the Baltic trade, incensed the English mercantile classes, and doubtless influenced the increases in customs duties which were regarded by the Germans as contrary to their treaty rights. Unsuccessful in obtaining redress from the English Government, the German merchants finally, in 1374, appealed for aid to the home towns, especially to Lübeck. The result of Hanseatic representations was the confirmation by Richard II. in 1377 of all their privileges, which accorded them the preferential treatment they had claimed and became the foundation of the Hanseatic position in England.

In the meanwhile, the conquest of Wisby by Waldemar IV. of Denmark in 1361 had disclosed his ambition for the political control of the Baltic. He was promptly opposed by an alliance of Hanse towns, led by Lübeck. The defeat of the Germans at Helsingborg only called into being the stronger town and territorial alliance of 1367, known as the Cologne Confederation, and its final victory, with the peace of Stralsund in 1370, which gave for a limited period the four chief castles on the Sound into the hands of the Hanseatic towns, greatly enhanced the prestige of the League.

The assertion of Hanseatic influence in the two decades, 1356 to 1377, marks the zenith of the League's power and the completion of the long process of unification. Under the pressure of commercial and political necessity, authority was definitely transferred from the Hansas of merchants abroad to the Hansa of towns at home, and the sense of unity had become such that in 1380 a Lübeck official could declare that "whatever touches one town touches all." But even at the time when union was most important, this statement went further than the facts would warrant, and in the course of the following century it became less and less true. Dortmund held aloof from the Cologne Confederation on the ground that it had no concern in Scandinavian politics. It became, indeed, increasingly difficult to obtain the support of the inland towns for a policy of sea-power in the Baltic. Cologne sent no representatives to the regular Hanseatic assemblies until 1383, and during the 15th century its independence was frequently manifested. It rebelled at the authority of the counter at Bruges, and at the time of the war with England (1469-74) openly defied the League. In the east, the German Order, while enjoying Hanseatic privileges, frequently opposed the policy of the League abroad, and was only prevented by domestic troubles and its Hinterland enemies from playing its own hand in the Baltic. After the fall of the order in 1467, the towns of Prussia and Livland, especially Danzig and Riga, pursued an exclusive trade policy even against their Hanseatic confederates. Lübeck, however, supported by the Bruges counter, despite the disaffection and jealousy on all sides hampering and sometimes thwarting its efforts, stood steadfastly for union and the necessity of obedience to the decrees of the assemblies. Its headship of the League, hitherto tacitly accepted, was definitely recognized in 1418.

The League Assembly.—The governing body of the Hansa was the assembly of town representatives, the "Hansetage," held irregularly as occasion required at the summons of Lübeck, and, with few exceptions, attended but scantily. The delegates were bound by instructions from their towns and had to report home the decisions of the assembly for acceptance or rejection. In 1469 the League declared that the English use of the terms "societas," "collegium" and "universitas" was inappropriate to so loose an organization. It preferred to call itself a "firma con-

federatio" for trade purposes only. It had no common seal, though that of Lübeck was accepted, particularly by foreigners, on behalf of the League. Disputes between the confederate towns were brought for adjudication before the general assembly, but the League had no recognized federal judiciary. Lübeck, with the counters abroad, watched over the execution of the measures voted by the assembly, but there was no regular administrative organization. Money for common purposes was raised from time to time, as necessity demanded, by the imposition on Hanse merchandise of poundage dues, introduced in 1361, while the counters relied upon a small levy of like nature and upon fines to meet current needs. Even this slender financial provision met with opposition. The German Order in 1398 converted the Hanseatic poundage to a territorial tax for its own purposes, and one of the chief causes for Cologne's disaffection a half-century later was the extension from Flanders to other parts of the Netherlands of the levy made by the counter at Bruges. Since the authority of the League rested primarily on the moral support of its members, allied in common trade interests and acquiescing in the able leadership of Lübeck, its only means of compulsion was the "Verhansung," or exclusion of a recalcitrant town from the benefits of the trade privileges of the League. A conspicuous instance was the exclusion of Cologne from 1471 until its obedience in 1476, but the penalty had been earlier imposed, as in the case of Brunswick, on towns which overthrew their patrician Governments. It was obviously, however, a measure to be used only in the last resort and with extreme reluctance.

The decisive factor in determining membership in the League was the historical right of the citizens of a town to participate in Hanseatic privileges abroad. At first the merchant Hansas had shared these privileges with almost any German merchant, and thus many little villages, notably those in Westphalia, ultimately claimed membership. Later, under the Hansa of the towns, the struggle for the maintenance of a coveted position abroad led to a more exclusive policy. A few new members were admitted, mainly from the westernmost sphere of Hanseatic influence, but membership was refused to some important applicants. In 1447 it was voted that admission be granted only by unanimous consent. No complete list of members was ever drawn up, despite frequent requests from foreign powers. Contemporaries usually spoke of 70, 72, 73 or 77 members, and perhaps the list is complete with Daenell's recent count of 72, but the obscurity on so vital a point is significant of the amorphous character of the organization.

The towns of the League, stretching from Thorn and Krakow on the east to the towns of the Zuider Zee on the west, and from Wisby and Reval in the north to Göttingen in the south, were arranged in groups, following in the main the territorial divisions. Separate assemblies were held in the groups for the discussion both of local and Hanseatic affairs, and gradually, but not fully until the 16th century, the groups became recognized as the lowest stage of Hanse organization. The further grouping into "Thirds," later "Quarters," under head-towns, was also more emphasized in that century.

Decline of the League.—In the 15th century the League, with increasing difficulty, held a defensive position against the competition of strong rivals and new trade-routes. In England the inevitable conflict of interests between the new mercantile power, growing conscious of its national strength, and the old, standing insistent on the letter of its privileges, was postponed by the factional discord out of which the Hansa in 1474 dexterously snatched a renewal of its rights. Under Elizabeth, however, the English Merchant Adventures could finally rejoice at the withdrawal of privileges from the Hanseatics and their concession to England, in return for the retention of the Steelyard, of a factory in Hamburg. In the Netherlands the Hanseatics clung to their position in Bruges until 1540, while trade was migrating to the ports of Antwerp and Amsterdam. By the peace of Copenhagen in 1441, after the unsuccessful war of the League with Holland, the attempted monopoly of the Baltic was broken, and, though the Hanseatic trade regulations were maintained on paper, the Dutch with their larger ships increased their hold on the herring

fisheries, the French salt trade and the Baltic grain trade. For the Russian trade new competitors were emerging in southern Germany. The Hanseatic embargo against Bruges from 1451 to 1457, its later war and embargo against England, the Turkish advance closing the Italian Black sea trade with southern Russia, all were utilized by Nuremberg and its fellows to secure a land-trade outside the sphere of Hanseatic influence. The fairs of Leipzig and Frankfurt-on-Main rose in importance as Novgorod, the stronghold of Hanse trade in the east, was weakened by the attacks of Ivan III. The closing of the Novgorod counter in 1494 was due not only to the development of the Russian State but to the exclusive Hanseatic policy which had stimulated the opening of competing trade routes.

Within the League itself increasing restiveness was shown under the restrictions of its trade policy. At the Hanseatic assembly of 1469, Danzig, Hamburg and Breslau opposed the maintenance of a compulsory staple at Bruges in the face of the new conditions produced by a widening commerce and more advantageous markets. Complaint was made of south German competition in the Netherlands. "Those in the Hansa," protested Breslau, "are fettered and must decline and those outside the Hansa are free and prosper." By 1477 even Lübeck had become convinced that a continuance of the effort to maintain the compulsory staple against Holland was futile and should be abandoned. But while it was found impossible to enforce the staple or to close the Sound against the Dutch, other features of the monopolistic system of trade regulations were still upheld. It was forbidden to admit an outsider to partnership or to co-ownership of ships, to trade in non-Hanseatic goods, to buy or sell on credit in a foreign mart or to enter into contracts for future delivery. The trade of foreigners outside the gates of Hanse towns or with others than Hanseatics was forbidden in 1417, and in the eastern towns the retail trade of strangers was strictly limited. The whole system was designed to suppress the competition of outsiders, but the divergent interests of individuals and towns, the pressure of competition and changing commercial conditions, in part the reactionary character of the legislation, made enforcement difficult. The measures were those of the late-mediaeval town economy applied to the wide region of the German Baltic trade, but not supported, as was the analogous mercantilist system, by a strong central government.

Among the factors, economic, geographic, political and social, which combined to bring about the decline of the Hanseatic League, none was probably more influential than the absence of a German political power comparable in unity and energy with those of France and England, which could quell particularism at home, and abroad maintain in its vigour the trade which these towns had developed and defended with their imperfect union. Nothing was to be expected from the declining empire. Still less was any co-operation possible between the towns and the territorial princes. The fatal result of conflict between town autonomy and territorial power had been taught in Flanders. The Hanseatics regarded the princes with a growing and exaggerated fear and found some relief in the formation in 1418 of a thrice-renewed alliance, known as the "Tohopesate," against princely aggression. But no territorial power had as yet arisen in north Germany capable of subjugating and utilizing the towns, though it could detach the inland towns from the League. The last wars of the League with the Scandinavian powers in the 16th century, which left it shorn of many of its privileges and of any pretension to control of the Baltic basin eliminated it as a factor in the later struggle of the Thirty Years' War for that control. At an assembly of 1629, Lübeck, Bremen and Hamburg were entrusted with the task of safeguarding the general welfare, and after an effort to revive the League in the last general assembly of 1669, these three towns were left alone to preserve the name and small inheritance of the Hansa which in Germany's disunion had upheld the honour of her commerce. Under their protection, the three remaining counters lingered on until their buildings were sold at Bergen in 1775, at London in 1852 and at Antwerp in 1863.

HANSEN, CHRISTIAN FREDERIK (1756-1845), Danish architect, was born at Copenhagen on Feb. 29, 1756. In 1804 he was appointed professor at the Academy, and head of the department of architecture. He was responsible for the rebuilding of the king's palace at Christiansborg, which had been burnt down in 1794, and he also designed the Frauenkirche in Copenhagen. He died on July 10, 1845.

HANSEN, EMIL CHRISTIAN (1842-1909), Danish botanist, was born on May 8, 1842, at Ribe, Jutland. He studied art at Copenhagen but in 1871 turned to science. From 1877 he was head of the physiological department of the Carlsburg institute. Hansen's researches were concerned chiefly with fungi and alcoholic fermenting yeasts. He was able to prove that there are different species of yeast and that they may be cultivated from a single cell. The yeast grown from single cells is now largely used in the bottom-fermentation breweries of the Continent. Hansen died at Copenhagen on Aug. 26, 1909. Besides numerous articles in periodicals, he wrote *Untersuchungen aus der Praxis der Gärungsindustrie* (2 vols., 3rd. ed., 1892-95. Eng. trans., 1896) and *Gesammelte theoretische Abhandlungen über Gärungsorganismen* (1911).

HANSEN, JENS ANDERSEN (1806-1877), Danish politician, was born on Jan. 7, 1806, at Odense. He was a master shoemaker, but later became the editor of the weekly democratic paper *Almuevennen* (1842), and of the *Morgenposten* (1856-64). In 1849 he became the leader of the liberal peasants party, whom he represented in the *Reichsrat* from 1856-66. An opponent of the Eiderdänen, he fought continually for the improvement of the conditions of the peasants.

He wrote *Vor Forfataings Historie 1848 til 1866* (2 vols., 1868-72), *Memoirenbrudstykke, mit livs Historie og Gjerning* (1875).

HANSEN, PETER ANDREAS (1795-1874), Danish astronomer, was born on Dec. 8, 1795, at Tondern, in the duchy of Schleswig. He learned the trade of a watchmaker, but in 1820 went to Copenhagen, where he won the patronage of H. C. Schumacher. He acted as Schumacher's assistant in work connected with the Danish survey, chiefly at the new observatory of Altona, 1821-25. Thence he passed on to Gotha as director of the Seeberg observatory. Hansen studied the problems of gravitational astronomy. A research into the mutual perturbations of Jupiter and Saturn secured for him the prize of the Berlin Academy in 1830, and a memoir on cometary disturbances was crowned by the Paris Academy in 1850. In 1838 he published a revision of the lunar theory, entitled *Fundamenta nova investigationis*, etc., and the improved Tables of the Moon based upon it were printed in 1857, at the expense of the British government, and were immediately adopted in the *Nautical Almanac*, and other Ephemerides. A theoretical discussion of the disturbances embodied in them (still familiarly known to lunar experts as the *Darlegung*) appeared in the *Abhandlungen* of the Saxon academy

of Sciences in 1862-64. Hansen received the Royal Astronomical Society's gold medal in 1842, and communicated to that society in 1847 a paper on a long-period lunar inequality (*Memoirs Roy. Astr. Society*, xvi.), and in 1854 one on the moon's figure (*Ib.* xxiv.). He was awarded the Copley medal by the Royal Society in 1850, and his Solar Tables, compiled with the assistance of Christian Olufsen, appeared in 1854. Hansen gave in 1854 the first intimation that the accepted distance of the sun was too great by some millions of miles (*Month. Notices Roy. Astr. Soc.* xv. 9). He died on March 28, 1874, at the new observatory in Gotha, erected under his care in 1857.

See *Vierteljahrsschrift astr. Gesellschaft*, x. *Month. Notices Roy. Astr. Society*, xxxv.; *Proc. Roy. Society*, xxv.; R. Wolf, *Geschichte der Astronomie*, *Wochenschrift für Astronomie*, xvii. (account of early years by E. Heis); *Allgemeine deutsche Biographie* (C. Bruhns).

HANSI, a town of British India, in the Hissar district of the Punjab, on a branch of the Western Jumna canal. Pop. (1921) 15,425. Hansi is one of the most ancient towns in northern India, the former capital of the tract called Haryana. At the end of the 18th century it was the headquarters of the famous Irish adventurer George Thomas; from 1803 to 1857 it was a British cantonment, and it became the scene of a murderous outbreak during the Mutiny. A ruined fort overlooks the town, which is a centre of local trade, with factories for ginning and pressing cotton.

HANSOM, JOSEPH ALOYSIUS (1803-1882), English architect and inventor, was born in York on Oct. 26, 1803, and died in London on June 29, 1882. He went from his father's joinery shop to be articled to an architect in York. In 1831 his designs for the Birmingham town hall were accepted and executed. In 1834 he registered and sold for £10,000 the design for a "Patent Safety Cab," which, as subsequently improved, became popular as the "hansom" cab. In the same year he joined Owen's Grand Trades Union. He erected a number of important buildings between 1854 and 1879, including churches, schools and convents for the Roman Catholic Church, of which he was a member. The cathedral, Plymouth, and the Jesuit church, Manchester, rank among his chief works. See "Memoir" in the *Builder*, July 8, 1882.

HANSON, JOHN (1715-1783), American patriot, was born in Charles county, Md., on Apr. 3, 1715, and educated in England. He became a political leader of note in Maryland, serving in the house of delegates, 1757-81, upon many important committees during the Revolutionary War, and as a representative of Maryland in the Continental Congress, 1781-83. On Nov. 5, 1781, he was elected by the Continental Congress "President of the United States in Congress Assembled," which office he held one year and resigned on account of feeble health. Because he was the first President under the Articles of Confederation he is sometimes referred to as "the first president of the United States," although he had none of the powers of the first president under the Constitution. He died at Oxen Hills, Md., on Nov. 27, 1783.

HANSON, SIR RICHARD DAVIES (1805-1876), chief justice of South Australia, was born in London on Dec. 6, 1805. Admitted a solicitor in 1828, he practised for some time in London. In 1838 he went with Lord Durham to Canada as assistant-commissioner of inquiry into crown lands and immigration. In 1840, on the death of Lord Durham, whose private secretary he had been, he settled in Wellington, New Zealand. He there acted as crown prosecutor, but in 1846 removed to South Australia. In 1851 he was appointed advocate-general of that colony. In 1856 and again from 1857 to 1860 he was attorney-general and leader of the government. In 1861 he was appointed chief justice of the supreme court of South Australia and was knighted in 1869. He died in Australia on March 4, 1876.

HANSSON, OLA (1860-1925), Swedish writer, was born at Hönsinge (Schöningen) on Nov. 12, 1860. He wrote mainly in German, but his best works are the lyrics inspired by the beauty of his native country. Both in his life and his books his morbid character is apparent, particularly in his first novel *Sensitiva Amoroza* (1887). He died on Sept. 26, 1925. In 1889, Hansson married Laura Marholm, author of several plays and novels.

Ola Hansson's most important works are: *Paras* (1890); *Vor der Ehe* (1895); *Ein Erzieher* (1895); *Jung Ofeg's Lieder* (1892). A collection of his poems appeared in 1901 as *Gedichte in Vers und Prosa*, and a Swedish collection in 1926. His later works include: *Das Verlorne Land* (1906); *Neue Lieder* (1907); *Auf dem Altar der Heimat* (1908).

HANSTEEN, CHRISTOPHER (1784-1873), Norwegian astronomer and physicist, was born at Christiania (Oslo) on Sept. 26, 1784. From the cathedral school he went to the university of Copenhagen, where he studied mathematics. In 1807 he began the inquiries in terrestrial magnetism with which his name is especially associated. He took in 1812 the prize of the Danish Royal Academy of Sciences for his reply to a question on the magnetic axes. Appointed lecturer in 1814, he was in 1816 raised to the chair of astronomy and applied mathematics in the university of Christiania. In 1819 he published a volume of researches on terrestrial magnetism, *Untersuchungen über den Magnetismus der Erde*, with a supplement containing *Beobachtungen der Abweichung und Neigung der Magnetnadel* and an atlas. Hansteen wished to determine the number and position of the earth's magnetic poles and to obtain observations for this purpose he travelled over Finland and the greater part of his own country; and in 1828-30 he undertook, in company with G. A. Erman, and with the co-operation of Russia, a government mission to western Siberia. A narrative of the expedition soon appeared (*Reise-Erinnerungen aus Sibirien*, 1854; *Souvenirs d'un voyage en Sibérie*, 1857); but the chief work was not issued till 1863 (*Resultate magnetischer Beobachtungen*, etc.). In 1833 an observatory was erected in the park of Christiania and Hansteen was appointed director. On his representation a magnetic observatory was added in 1839. He wrote (1842) *Disquisitiones de mutationibus quas patitur momentum acus magneticae*, and contributed various papers to scientific journals, especially the *Magazin for Naturvidenskaberne*, of which he became joint-editor in 1823. He superintended the trigonometrical and topographical survey of Norway, begun in 1837. In 1861 he retired from active work, but still pursued his studies, his *Observations de l'inclination magnétique et Sur les variations séculaires du magnétisme* appearing in 1865. He died on April 11, 1873.

See *Proc. of Amer. Acad.* (1874).

HANTHAWADDY, a district in the Pegu division of Lower Burma, the home district of Rangoon, from which the town was detached to make a separate district in 1880. It has an area of 1,866 sq.m., with a population in 1921 of 492,429, of whom 43,429 lived in the two towns of Syriam, where the oil refineries are situated, and Thongwa. Ma-ubin and Hanthawaddy are the two most densely populated districts in the province. It consists of a vast plain stretching up from the sea, and lies on either side of the Rangoon river by which the port of Rangoon is approached from the sea. The country is intersected by numerous tidal creeks, many navigable by large boats and some, like the Bassein creek which connects the Rangoon river with the To or China Bakir mouth of the Irrawaddy, by steamers. The Twanté canal affords a more direct communication between the Rangoon and China Bakir rivers, and is used by the regular steamer services between Rangoon and Bassein across the delta. The British Admiralty oiling base, constructed between 1922 and 1927, lies on the east bank of the Rangoon river in the Hanthawaddy district. Cultivation in the district is almost wholly confined to rice, and there are considerable tracts of unreclaimed marshland.

HANUKKAH (lit. dedication, cf. Num. vii.), the feast instituted by Judas Maccabaeus on 25 Kislew, 165 B.C., for the purification of the Temple, on the third anniversary of the setting up of the "Abomination of Desolation" (Dan. xi. 31; 1 Macc. i. 41-64, iv. 59; 2 Macc. vi. 2; Mark xiii. 14) by Antiochus Epiphanes. The name חנוכה corresponds to ἑγκαίνια (John x. 22). Wellhausen maintained that Hanukkah represents a primitive winter solstice festival. On this see ch. xii. of C. C. Keet (*Liturgical Use of Psalter*, London, 1928). The feast lasts eight days, but the legend in 2 Macc. i. 18 is probably not the reason for this. One light is kindled on the first night, an extra one being added on each successive night, Hillel's rule thus prevailing over

that of Shammai. The scroll of Antiochus still survives in some liturgies. For the service see the prayer books of S. Singer (Ashkenazic rite, London, 1928, and I. Abraham's notes in the annotated edition) and M. Gaster (Sephardic rite, with variants, Oxford, 1901); I. Elbogen in *Jüd. Gottesdienst* (Frankfurt a. M. 1924); G. F. Moore, *Judaism*, ii. 49, Harvard, 1927). The *Jewish Encyclopedia* (s.v.) article contains numerous illustrations of Hanukkah lamps: see also the catalogue of the Anglo-Jewish Historical exhibition of 1887 (published by the *Jewish Chronicle*, London). Specimens will be found in museums and private collections. In modern days services for Jewish soldiers in the British army are held on *Hanukkah*.

HANUMĀN, in Hindu mythology, the monkey-god, a central figure in the *Rāmāyana*. Child of a nymph by the wind-god, he aided Rāma to recover his wife, Sita, from the demon Ravana, bridging the strait between India and Ceylon with boulders brought from the Himalayas, with the help of a host of monkeys. Temples in his honour are numerous, especially in southern India. He is also a popular deity in Japan, where many temples are erected to his honour and districts of towns bear his name. The hanumān monkey (*Semnopithecus entellus*), called after the god, is one of the commonest Indian monkeys. (See PRIMATES.)

HANUSCH, FERDINAND (1866-1923), Austrian politician, was born Nov. 9, 1866 in Oberndorf, Silesia, the son of a poor Silesian weaver. After a childhood of crushing poverty, Hanusch became in 1900 secretary of the Austrian Textile Workers' Union. In 1907 he entered Parliament as a deputy. He was a pioneer of the Austrian trade union movement, especially in his own branch of industry, and did much to improve conditions for this class of labour, which were abnormally bad. In Oct. 1918 he became secretary of state of the new ministry of social welfare, and was author of most of the social legislation of the period, including the eight-hour day, the Works Councils act, the law compelling employers of 14 hands or more to increase their staffs by 20% in order to reduce unemployment, and the laws dealing with the unemployment dole. He was universally respected for his personal probity and first-hand knowledge of labour problems and conditions. He died Sept. 28, 1923.

HANWAY, JONAS (1712-86), English traveller and philanthropist, was born at Portsmouth on Aug. 12, 1712. In 1743 he became a partner with Dingley, a merchant in St. Petersburg. He travelled across Russia to Persia where he suffered many hardships and difficulties. Hanway returned in 1750 to London, where he died on Sept. 5, 1786. He is said to have been the first Londoner habitually to carry an umbrella, and he lived to triumph over all the hackney coachmen who tried to hoot and hustle him down. Hanway was a prison reformer, and he attacked the employment of children as chimney sweeps.

Hanway left 74 printed works, mostly pamphlets; the only one of literary importance is the *Historical Account of British Trade over the Caspian Sea, with a Journal of Travels*, etc. (London, 1753). On his life, see also Pugh, *Remarkable Occurrences in the Life of Jonas Hanway* (London, 1787); *Gentleman's Magazine*, vols. xxxii., lvi., vol. lxx.; *Notes and Queries*, 1st series, i.; 3rd series, vii.; 4th series, viii.

HANWELL, urban district of Middlesex, England, 10½ m. W. of St. Paul's cathedral, London. Pop. (1921) 20,481. It is a residential suburb of London. Many of its inhabitants are employed in metal industries, in electrical works and in furniture factories. The mental hospital has accommodation for over 2,500 patients. Before the Norman period the manor of Hanwell belonged to Westminster Abbey.

HAPARANDA, a town of Sweden in the district (*län*) of Norbotten, at the head of the Gulf of Bothnia. Pop. (1928) 2,624. It lies about 1½ m. from the mouth of the Torne river, on the frontier with Finland, opposite the town of Torneå. The towns are divided by a marshy channel. Haparanda was founded in 1812, and at first bore the name of Karljohannstad. Some ship-building is done and tar is exported. Sea-going vessels load and unload at Salmio, 7 m. from Haparanda. Mean temperature, February 10.6°; July 59.0°. Rainfall, 16.5 in. annually. Up the Torne valley (54 m.) is the hill Avasaxa, whither pilgrimages were formerly made in order to stand in the light of the sun at midnight on St. John's day (June 24).

HAPUR, a town of British India in the Meerut district of the United Provinces, 18 m. S. of Meerut. Pop. (1921) 20,388. It is said to have been founded in the 10th century, and was granted by Sindhia to his French general Perron at the end of the 18th century. Several fine groves surround the town, but the wall and ditch have fallen out of repair, and only the names of the five gates remain. Considerable trade is carried on in sugar, grain, cotton, timber, bamboos and brass utensils. Babugarh, an important depot and farm for military remounts adjoins the town.

HARA, TAKASHI (1856-1921), Japanese politician, was born at Morioka. After studying law and practising journalism he entered the diplomatic service, and was *chargé d'affaires* in Paris in 1886. In 1892 he was appointed director of the commercial bureau at the Foreign Office, and in 1895 became vice-minister of the department. He acted as minister to Korea from 1896-97, when he became chief editor of the Osaka *Mainichi*. Still deeply interested in politics he became the leading spirit of the Seiyu-Kai (Liberal) party. From the end of 1900 to May 1901 he was minister of communications in the Ito ministry. He then became chief editor of the Osaka *Shimpo*, and was elected a member of the House of Representatives for Morioka in 1902. Definitely abandoning journalism he was appointed minister for home affairs in the first Saionji ministry of 1906, in the second Saionji ministry of 1911 and in the Yamamoto ministry of 1913. On Sept. 29, 1918 Hara, as the first commoner to become prime minister of Japan, formed a cabinet based, for the first time in the history of Japanese politics, on strictly parliamentary principles. He was assassinated by a demented youth in Tokyo on Nov. 4, 1921.

HARA-KIRI, self-disembowelment (Japanese *hara*, belly, and *kiri*, cutting), the method of suicide permitted to offenders of the noble class in feudal Japan and later the national form of honourable suicide. The more commonly used modern term is *Seppuku*, the Chinese reading of the same characters. Hara-kiri was a growth of mediaeval militarism, prompted by the desire of the noble to escape the humiliation of falling into an enemy's hands. By the end of the 14th century the custom had become a valued privilege. Hara-kiri was of two kinds, obligatory and voluntary. The first is the more ancient. An official or noble, who had broken the law or been disloyal, received a message from the mikado, couched always in gracious terms, courteously intimating that he must die. The mikado usually sent a jewelled dagger with which the deed might be done. The suicide made dignified preparations for the ceremony. In his own baronial hall, or in a temple, a dais, 3 or 4 in. from the ground, was constructed. Upon this was laid a rug of red felt. The suicide, clothed in his ceremonial dress, and accompanied by his second (Kaishaku), took his place on the mat, the officials and his friends ranging themselves in a semi-circle. The weapon was then handed to him with many obeisances by the mikado's representative, and he made a public confession of his fault. A moment later he plunged the dagger into his stomach below the waist on the left side, drew it slowly across to the right and, turning it, gave a slight cut upward. At the same moment the Kaishaku, who crouched at his friend's side, leaping up, brought his sword down on the outstretched neck. The bloodstained dagger was taken to the mikado as a proof of the consummation of the act. The performance of hara-kiri carried with it certain privileges. If it was by order of the mikado half only of a traitor's property was forfeited to the State. If the gnawings of conscience drove the disloyal noble to voluntary suicide, his dishonour was wiped out, and his family inherited all his fortune.

Voluntary hara-kiri was the refuge of men rendered desperate by private misfortunes, or was committed from loyalty to a dead superior, or as a protest against what was deemed a false national policy. This voluntary suicide still survives, a characteristic case being that of the citizen who despatched himself in 1925 as a protest against the Government's foreign policy. The popularity of this self-immolation is testified to by the fact that for centuries no fewer than 1,500 hara-kiris are said to have taken place annually, at least half being entirely voluntary. Stories of amazing heroism are told in connection with the per-

formance of the act. Obligatory hara-kiri was actually abolished in 1868.

See A. B. Mitford, *Tales of Old Japan*; Basil Hall Chamberlain, *Things Japanese* (1898).

HARALD I. (850-933), surnamed Haarfager ("Fairhair"), first king over Norway, succeeded on the death of his father Halfdan the Black in A.D. 860 to the sovereignty of several small and somewhat scattered kingdoms, which had come into his father's hands through conquest and inheritance and lay chiefly in south-east Norway. (See NORWAY.) In 866 he made the first of a series of conquests over the many petty kingdoms which then composed Norway; and in 872, after a great victory at Hafrsfjord near Stavanger, he found himself king over the whole country. His realm was, however, threatened by dangers from without, as large numbers of his opponents had taken refuge, not only in Iceland, then recently discovered, but also in the Orkneys, Shetlands, Hebrides and Faeroes, and in Scotland itself; and from these winter quarters sallied forth to harry Norway as well as the rest of northern Europe. Their numbers were increased by malcontents from Norway, who resented Harald's claim of rights of taxation over lands which the possessors appear to have previously held in absolute ownership. At last Harald was forced to make an expedition to the west to clear the islands and Scottish mainland of Vikings. Numbers of them fled to Iceland, which grew into independent commonwealth, while the Scottish isles fell under Norwegian rule. The latter part of Harald's reign was disturbed by the strife of his many sons. He gave them all the royal title and assigned lands to them which they were to govern as his representatives; but this arrangement did not put an end to the discord, which continued into the next reign. When he grew old he handed over the supreme power to his favourite son Erik "Bloody Axe," whom he intended to be his successor. Harald died in 933, in his 84th year.

The tale goes that the scorn of the daughter of a neighbouring king induced Harald to take a vow not to cut or comb his hair until he was sole king of Norway and that ten years later he was justified in trimming it whereupon he exchanged the epithet "Shockhead" for the one by which he is usually known.

HARALD II., surnamed Graafeld, a grandson of Harald I., became, with his brothers, ruler of the western part of Norway in 961; he was murdered in Denmark in 969.

See H. Hermannson, *Islandica III.* (Bibliography of the Sagas of the Kings of Norway) (1910). A. Bugge, *Norges Historie* Vol. I. part II. (1909-10).

HARALD III. (1015-1066), king of Norway, surnamed Haardraade, which might be translated "ruthless," was the son of King Sigurd and half-brother of King Olaf the Saint. At the age of fifteen he was obliged to flee from Norway, having taken part in the battle of Stiklestad (1030), at which King Olaf met his death. He took refuge for a short time with Prince Yaroslav of Novgorod (a kingdom founded by Scandinavians), and thence went to Constantinople, where he took service under the empress Zoe, whose Varangian guard he led to frequent victory in Italy, Sicily and North Africa, also penetrating to Jerusalem. In the year 1042 he left Constantinople, the story says because he was refused the hand of a princess, and on his way back to his own country he married Ellisif or Elizabeth, daughter of Yaroslav of Novgorod. In Sweden he allied himself with the defeated Sven of Denmark against his nephew Magnus, now king of Norway, but soon broke faith with Sven and accepted an offer from Magnus of half his kingdom. In return for this gift Harald is said to have shared with Magnus the enormous treasure which he had amassed in the East. The death of Magnus in 1047 put an end to the growing jealousies between the two kings, and Harald turned his attention to subjugating Denmark, which he ravaged year after year; but in 1064 he gave up the attempt and made peace. In 1066, possibly instigated by the banished Earl Tostig, he invaded England. In September 1066 he landed in Yorkshire with a large army, reinforced from Scotland, Ireland and the Orkneys; took Scarborough by casting flaming brands into the town from the high ground above it; defeated the Northumbrian forces at Fulford; and entered York on Sept. 24. But

on the 25th the English Harold arrived from the south, and routed his forces at Stamford Bridge after the fall of their king. His many victories in the face of great odds prove him to have been a remarkable general, of never-failing resourcefulness and indomitable courage, in spite of the fact that he was an unpopular king.

HARALD IV. (d. 1136), king of Norway, surnamed Gylle (probably from *Gylle Krist*, i.e., servant of Christ), was born in Ireland about 1103. About 1127 he went to Norway and declared he was the son of King Magnus III. (Barefoot), who had visited Ireland just before his death in 1103, and consequently a half-brother of the reigning king, Sigurd. He appears to have submitted successfully to the ordeal of fire, and the alleged relationship was acknowledged by Sigurd on condition that Harald did not claim any share in the government of the kingdom during his lifetime or that of his son Magnus. Harald kept this agreement until Sigurd's death in 1130. Then war broke out between himself and Magnus, who was captured in 1134, blinded, and imprisoned. Harald now ruled the country until 1136, when he was murdered by Sigurd Slembi-Diakn, another bastard son of Magnus Barefoot. Four of Harald's sons, Sigurd, Ingi, Eysteinn and Magnus, were subsequently kings of Norway.

HARAR, a province and city of Abyssinia. The province is one of the largest and most fertile in the country, situated at an elevation of some 4,000 to 5,000 feet above sea-level, enjoying a pleasant climate, and rich in varied cultivation. It is under the personal governorship of Ras Tafari the regent and heir to the throne, proclaimed Negus in 1928, and is administered by Dajazmach Imeru his uncle, as sub-governor. It is famous for its excellent coffee, which is grown extensively and largely exported.

Along its northern extremity runs the Franco-Ethiopian railway from Jibuti to Addis Ababa, on which 311 kilo. from Jibuti is the town of Diredawa the most progressive town in Abyssinia with a population of over 30,000 rejoicing in roads, a water supply and electric light; it was for many years the terminus of the railway. 35 miles S.W. of Diredawa lies the town of Harar, the capital of the province and for long its most important centre until the advent of the railway transferred its commercial predominance to Diredawa.

It is still, however, the centre of the caravan trade of the province and in addition to coffee there is a good deal of trade in durra, the Kat plant (used by Mohammedans as a drug), ghee, cattle, mules and camels, skins and hides, ivory and gums. Cotton goods form the bulk of the import trade. Harar is built on the slopes of a hill at an elevation of over 5,000 feet. A lofty stone wall, pierced by five gates and flanked by twenty-four towers, encloses the city, which has a population of about 40,000. The streets are steep, narrow, dirty and unpaved, the roadways consisting of rough boulders. The houses in general are made of undressed stone and mud and are flat-topped, the general aspect of the city being Oriental and un-Abyssinian. A few houses, including the palace of the governor and the foreign consulates, are of more elaborate and solid construction than the majority of the buildings.

Harar is believed to owe its foundation to Arab immigrants from Yemen in the 7th century of the Christian era. In the region of Somaliland, now the western part of the British protectorate of that name, the Arabs established the Moslem state of Adel or Zaila, with their capital at Zaila on the Gulf of Aden, Harar becoming the seat of government in 1521. A subsequent Emir of Harar Mohammed surnamed Grañ (left-handed) probably a Somali, is famous for his invasion of Abyssinia, of which country he was virtual master for several years until his defeat and death in 1541. It was first visited by a European in 1854 when (Sir) Richard Burton spent ten days there in the guise of an Arab. In 1875 Harar was occupied by an Egyptian force and remained in the possession of Egypt until 1885, when the garrison was withdrawn in consequence of the rising of the Mahdi in the Sudan. A son of the ruler who had been deposed by Egypt was installed as Emir, the arrangement being carried out under the superintendence of British officers. The new Emir held power

until January 1887, in which month Harar was conquered by Menelek II., king of Shoa (afterwards emperor of Abyssinia). The governorship of Harar was by Menelek entrusted to Ras Makonnen, who held the post until the time of his death in 1906.

The Harari proper are of a stock distinct from the neighbouring peoples, and speak a special language. Hararese is "a Semitic graft inserted into an indigenous stock" (Sir R. Burton, *First Footsteps in East Africa*). The Harari are Mohammedans of the Shafa'i or Persian sect, and they employ the solar year and the Persian calendar. In addition to the native population there are in Harar colonies of Abyssinians, Somalis and Gallas. By the Somalis the place is called Adari, by the Gallas Adaray.

See ABYSSINIA; SOMALILAND. Also P. Paulitschke, *Harar: Forschungsreise nach den Somäl- und Galla-Ländern Ost-Afrikas* (Leipzig, 1888). (C. F. R.)

HARBIN, the chief city of Central Manchuria. It lies on the right bank of the Sungari river in the province of Kirin in 45° 30' N. lat. and 126° 40' E. long., 220 miles N.N.E. of Moukden and 250 miles W.N.W. of Vladivostok, with both of which towns it is connected by railway. The growth of the town has been phenomenal. In 1898 Harbin was only a local wheat market. To-day it is a populous industrial city and a centre of keen international rivalry. It is the second largest town in Manchuria with a population of about 220,000, highly composite in character. The largest single element is the 194,000 Chinese, mainly in the Fu-Chia-tien suburb, whilst Russians preponderate amongst the remainder. The city has three distinct sections: the Pristan (or "wharf"), the main business quarter, New Harbin (on the plateau behind the "wharf" district), the administrative quarter, and Old Harbin, now the foreign residential quarter. Harbin is the creation of the Chinese Eastern railway, being administered by a mixed council appointed by the railway and occupying 1,400 acres of the 29,000 acres leased to the company. The surrounding plain, composed mainly of fertile black loam and some yellow clays, is very suitable for the growth of wheat, maize, corn and that very adaptable plant, the soya bean. Harbin is also well situated in relation to markets. By the Chinese Eastern Railway, both the eastern and western frontiers can be reached in five hours, whilst it is only a journey of eight hours to Changchun where connection is made with the South Manchuria Railway leading to Monkden, Dairen and Korea. The Sungari river is navigable during the months from April to October, but only bulky produce such as timber favours this route. The rapid increase recorded in motor vehicles throughout Harbin, is in itself most significant and provides a welcome relief to the existing pressure on the railway facilities.

Harbin is the focus of movements influencing Manchuria and on the economic side this rôle is evidenced by the diversified character of its industries. The main industries have an agricultural basis, such as flour milling, soya bean factories, distilleries, leather, etc. In 1926 there were more than 60 factories manufacturing soya bean products (flour, cake, oil) and in the same year there were 17 wheat flour factories and 7 large firms making alcoholic liquors. In these enterprises the Chinese are now the largest investors, although there is much Russian and Japanese capital involved. To cope with the demands of these firms and numerous other concerns, there are six electric light and power companies. Harbin exports bean products, wheat and wheat flour, soap, dyes, leather products and tobacco. The outlets of Harbin are Vladivostok and Dairen via Changchun. Harbin's exports show an increasing tendency to go along the Suifenho-Vladivostok route, despite the efforts of the (Japanese) South Manchuria railway. The imports of the Harbin district are, however, mainly of Japanese origin, comprising textile goods, tobacco, sugar, cutlery and hardware. The total trade of Harbin district according to the statistics for 1926 was 78,891,478 Hk. Tls. of which 60,698,431 Hk. Tls. were exports and 15,826,851 Hk. Tls. were foreign imports.

HARBINGER, originally one who provided shelter for an army (from M.E. *herbergere*, formed from O.H. Ger. *heri*, an

army, and *bergen*, shelter). The meaning was enlarged to include any place where travellers could be lodged, and also the person who provided lodgings, or one who went on before a party to secure lodgings; hence, figuratively, in literature a fore-runner. A harbinger was also the herald sent to announce the king's coming, and until 1846 a Knight Harbinger was an officer in the royal household.

HARBINGER OF SPRING (*Erigenia bulbosa*), a small North American plant of the parsley family (Umbelliferae), native to moist low woods from southern Ontario to Minnesota and southward to Pennsylvania, Alabama and Missouri. It is a low, smooth, almost stemless perennial, rising from a deep round tuber and bearing near the ground from two to four compound leaves thrice divided into narrow leaflets and a flower-stalk (scape), 3 to 9 in. high, terminating in small umbellate clusters of white flowers. In the southern part of its range the plant blooms as early as February and at the north in April, whence its name. It is somewhat rare and local in many sections but is especially abundant in the vicinity of Washington, D.C.

HARBORD, JAMES GUTHRIE (1866—), American soldier, was born at Bloomington, Ill., March 21, 1866. He graduated from the Kansas State Agricultural college, Manhattan, Kan., taking the degree of B.S. in 1886. He joined the 4th Infantry in 1889 and was commissioned in the cavalry in 1891. Serving in the 5th, 10th, 11th and 1st Cavalry, he became a major in 1914. From 1903-14 he served in the Philippine Constabulary. He became brigadier general in 1917, and was chief of staff of the A.E.F. in France 1917-18. He commanded the Marine Brigade near Château-Thierry, June 1918, being appointed major general on June 26. He commanded the 2nd Div. A.E.F. in the Soissons offensive under Mangin, July 1918, after which he was placed in command of Service of Supply. He was reappointed chief of staff A.E.F., May 26, 1919, and was head of the American military mission to Armenia, Aug. 1919. He served as deputy chief of staff, U.S. Army, 1921-22. Retiring from the army Dec. 29, 1922, he became president of the Radio Corporation of America. He published *Leaves from a War Diary*, in 1925.

HARBOURS. A harbour is a sheltered area of water wherein vessels may take refuge and may safely lie at anchor or moored to buoys. In some cases the harbour forms an intermediate access channel or sheltered anchorage lying between the open sea and the docks or quays at which the business of a port is carried on. In many harbours enjoying sufficient protection, natural or artificial, there is no definite line of demarcation between this intermediate area and that occupied by the open basins, quays and jetties where vessels berth, some convenient and well sheltered position being selected for this purpose. In some harbours there is, however, an outer protected area providing comparatively tranquil water, even in stormy weather, from which an inner harbour may be entered. The inner harbour, protected by piers or minor breakwaters, is usually provided with tidal quays at which vessels berth, as at Holyhead, or affords access to closed docks.

Harbours are necessary to all classes of seagoing vessels. The requirements of shipping do indeed vary, within wide limits, as regards the accommodation, facilities, degree of shelter and depth of water to be provided; and, whilst one harbour may be capable of accommodating all or any classes of vessel, the circumstances of another may limit its usefulness to small craft. Many tidal harbours, owing to limitations of depth, can be entered only at or near high water. Some of minor importance are dry, or nearly dry, at low water, and vessels using them must take the ground. The present article describes some of the more important and typical examples, both natural and artificial, the principles on which artificial harbours are—or should be—planned, and the means by which natural facilities have been improved and supplemented by artificial works. The guiding principles to be followed in the making of small harbours are the same, *mutatis mutandis*, as those which are applicable to the great achievements of maritime engineering construction on which millions of money have been expended.

Breakwaters, which constitute the principal protection works of most artificial harbours, are described in a separate article;

for the interior works and facilities of a port see *Docks*; river and estuarine harbours are also referred to in the article *RIVER ENGINEERING*; and for the lighting and buoys of harbours see *LIGHT-HOUSES* and *BUOYS*. See also *DREDGING* and *JETTY* and, for further particulars of individual harbours, under place names, e.g., *CHEERBOURG*, *RIO DE JANEIRO*.

Classification.—Harbours may be classified in several ways:

1. *Natural harbours*, possessing, in a large degree, natural shelter. These require only the provision of such facilities as docks or piers, and sometimes deepening by artificial means, to make them serviceable as shipping ports. Such are the land-locked harbours of Hongkong, Rio de Janeiro, New York, Portsmouth and Sydney. Some estuarine harbours, such as those formed by the lower tidal compartments of the Thames, Mersey and Yangtse, also come under this heading.

2. *Harbours possessing partial natural shelter improved by artificial means*, e.g., Plymouth and Table Bay.

3. *Harbours entirely (or almost entirely) of an artificial nature* formed on open sea coasts. A notable example of this class is Madras harbour (fig. 2).

Another classification, of an arbitrary and somewhat artificial nature, divides harbours according to their respective purposes, e.g., harbours of refuge, commercial harbours, naval harbours and fishery harbours. It may be explained here that the term "harbour of refuge" (now almost obsolete) ordinarily denotes a harbour constructed specifically and primarily for the purposes of shelter (usually for small craft), and not as an essential factor of a naval or commercial port.

Still another method classifies harbours according to their physical characteristics and the nature of the artificial works employed for their creation or improvement; as for instance:—(a) lagoon harbours, (b) jetty harbours, (c) harbours formed by converging breakwaters projected from the shore, (d) those protected by breakwaters parallel with the shore, (e) those formed by the projection of breakwaters from one or both horns of a bay, and (f) harbours where island breakwaters cover and protect embayments.

EARLY HISTORY

There is no conclusive evidence as to the date or the locality of the first artificial harbour construction. The use of natural havens and places of shelter must, of course, have been contemporary with the origins of navigation, and there are evidences of intercourse between Egypt and Crete in the pre-dynastic period of Egypt over 6,000 years ago. There are remains of very ancient harbour works in Crete, but, owing to earth movements most of them are under water. M. Gaston Jondet claims, in *Les ports submergés de l'ancienne Ile de Pharos* (Institut Egyptien, 1916), to have discovered at Alexandria vestiges of an ancient harbour in the Cretan manner, but the date and origin of these remains have been disputed (see also Sir A. Evans' *The Palace of Minos*, vol. i, 1921, and authorities there cited). These works are said to date from c. 2000 B.C. and to have been constructed on the seaward side of the island of Pharos, whereas the later harbour of Alexander (c. 332 B.C.) was placed between the island and the mainland. The Cretans did not confine their maritime adventure to the eastern Mediterranean, and Sir Arthur Evans is of opinion that there was trade between Crete and Britain in the early Bronze Age, between 1600 and 1200 B.C., centuries before the first coming of the Phoenicians to Britain. The Phoenicians built harbours at Sidon and Tyre in the 13th century B.C. The second city of Tyre was built on a small island off the coast. On either side of this island harbours were constructed protected by moles which appear to have been formed of rubble stone surmounted by masonry walls. These harbours and the city were of considerable extent and importance. In 332 B.C. Alexander the Great captured and destroyed the city, after building a causeway from the mainland to the island, and the port fell into decay. The causeway held up the drifting sands which accumulated on either side of it and the site of Tyre is now a peninsula.

It was after the capture of Tyre that Alexander founded the city of Alexandria and built the second harbour. He connected

the island of Pharos with the mainland by a causeway, called the Heptastadion, which had two bridged openings in it. Later the famous lighthouse of the Pharos was built and moles were constructed affording additional protection to the east and west harbours on either side of the causeway (see E. Quellenec, *Egyptian Harbours*, XIV. Int. Congress of Nav. 1926).

Many other Mediterranean harbours, both natural and artificial, were of considerable commercial or military importance in Greek and Roman times. The natural harbours of Tarentum (Taranto) and Brundisium (Brindisi) are still in use. Ostia, once the port of Rome, is said by some classical writers to have been founded in the 7th century B.C., but the port of the empire was built by Claudius and extended by Trajan about 100 A.D. (See *Proc. Inst. C.E. Vol. IV.*, 1845). In Trajan's reign Civita Vecchia, 30 m. north of the Tiber mouth, was founded and Ostia was eventually abandoned as a port on account of the silting up of the approaches to it. The site of the harbour is now over 2 m. from the sea.

In mediaeval times the prosperity of such Mediterranean cities as Venice and Genoa led to the building of harbour works for the accommodation of their seaborne trade. Some of the early works at Genoa and on the Venetian lagoons remain to this day. Natural harbours suitable to the needs of the trade of the middle ages are more numerous in northern Europe than in the tideless Mediterranean sea, and for many centuries these natural facilities, combined in some cases with artificial works of the simplest character, sufficed for the shipping of the times.

One of the earliest protection works built at a seaport in England was the Cobb at Lyme Regis dating from the 14th century. This was a pier or jetty constructed of rough boulders held in place between rows of oak piles. A pier occupying the same site still bears its name. Harbour works are said to have existed about 1250 at Hartlepool and at Arbroath in Scotland c. 1394. Dover was a busy port in the time of Henry VIII., and a stone and timber breakwater was built there in his reign. Towards the end of the 16th century the first of the jetties at the entrance to the Yare at Yarmouth was constructed; and in the 17th century protection piers were built at Whitby and Scarborough, portions of which still exist. It was not, however, until the second half of the 18th century when John Smeaton (*q.v.*) began his career, that the building of harbour works on any considerable scale was undertaken in England. Smeaton must be regarded as the founder in England of the science of harbour engineering. His work and that of his successors, Thomas Telford and John Rennie, permanently established British seaports in the forefront of progress in harbour construction.

On the other side of the channel, Havre, Dieppe, Rochelle and Dunkirk were among the earliest ports to embark on harbour construction; in Bélidor's *Architecture Hydraulique* (Paris, 1737-53) is a detailed account of the early harbour at Dunkirk as well as of other ancient port works.

PRINCIPLES OF DESIGN

In designing the works of a harbour one of the most important considerations is that of exposure. Such information as can be obtained from reliable charts must be supplemented by more detailed marine surveys and soundings, and the nature of the sea bed must be ascertained by borings and probings. Among the points to be noted are:—the geological and other physical characteristics of the site; the slope of the sea bed; the depth of water seaward of the proposed site as well as over it; the presence of any outlying reefs, rocks, shoals or islands of which advantage can be taken as affording protection, or as good foundations for sheltering works; and the tidal phenomena, such as the vertical range. Investigation must be made of the nature and directions of the currents and tidal streams; the effect of littoral drift; the nature and extent of natural shelter; the directions of the prevailing and of the strongest winds; the line of maximum exposure, or the greatest fetch or reach of the sea in any unobstructed line of direction; the probable maximum height of the waves due to the exposure; and the direction from which the heaviest seas come. These and other considerations determine the character of

the works to be constructed. In the case of harbours proposed to be made at the mouths of rivers or in estuaries, many other problems relating to river flow, bars, the maintenance of channels, etc., call for investigation.

There is a great diversity in the height of waves experienced in different positions on the same coastline. In some places shores lie open to the full force of the ocean waves while other parts of the same coast are protected by projecting headlands or islands, or by outlying reefs or sandbanks. Then again, inlets and enclosed arms of the sea, creeks, and river mouths, estuaries and landlocked lagoons provide sites more or less sheltered from wind and waves according to the degree of natural protection afforded them. At the other extreme is the exposed open site where breakwaters are necessary to protect an anchorage harbour, and where secondary breakwaters or piers may be required to provide local and complete shelter for the inner works of the port.

In planning a harbour to be formed in an exposed situation, certain important points must be kept in view, *e.g.*, (1) The entrance should be so placed as to afford ample sea room, free from rocks and shoals on a lee shore, for a vessel when on the point of entering or immediately after leaving the shelter of the outer and covering breakwater or breakwaters. (2) The alignment of the works should be such as to minimize the wheeling effect of waves around a breakwater head and the projection of seas across the entrance. (3) If possible the entrance should be so placed that one breakwater overlaps the other in such a way that some shelter from the direction of the heaviest seas is afforded to a ship when passing the harbour entrance. (4) The entrance should be planned so as to avoid strong currents sweeping across it. (5) Ample expending beaches or wave traps should be provided inside a harbour whose entrance is exposed, to allow the waves that pass the entrance to spend and break themselves. For this reason such a harbour surrounded with vertical walls, where there is not ample spending room, becomes a "boiling pot" of reflected waves; and in these circumstances sloping walls are preferable.

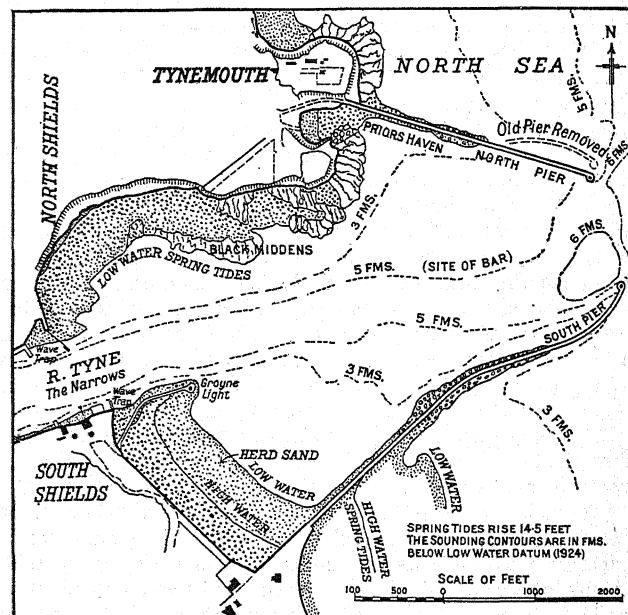

FIG. 1.—TYNEMOUTH HARBOUR

(6) The width of entrance, while being sufficient for the safe passage of ships, should be restricted as much as practicable; for upon the relation of the entrance width to the internal width and area of the harbour largely depends the reduction of range¹

¹Range, applied to waves, denotes the vertical rise and fall of sea waves particularly when they are propagated into a harbour; windlop describes the short wind waves generated in narrow waters as distinct from the ocean wave. The amplitude of the vertical motion of a ship due to range of waves is known as scend; tidal range is the vertical rise and fall of a tide; tidal rise the height of a tide at high-water above the chart datum which is usually the level of the lowest low-water.

BAY, ESTUARY AND DEEP WATER RIVER-HARBOURS

1. The inner harbour, entrance lock and docks at Le Havre, an important French port of call and transit situated on the English Channel. Originally constructed in sheltered water at the mouth of the Seine estuary, the port has since been extended into more exposed water. There are more than 8 miles of quayage.
2. View of New York harbour showing Upper Bay which forms the embouchure of the East river (left) and the Hudson River (right). Both rivers are important arteries of coastwise and inland commerce and are lined with piers and wharves at which the largest vessels are accommodated.
3. Hong Kong harbour as seen from the heights above Victoria, Capital of the island of Hong Kong. The naturally sheltered harbour, which is 10 sq. m. in area and possesses an east and a west entrance, is one of the chief ports on the coast of China and has a vast trans-shipment trade.
4. Group of the older docks at Liverpool including the Sandon entrance and half-tide dock entered from the river Mersey. The docks at Liverpool and at Birkenhead on the opposite side of the Mersey cover an enclosed water area of over 700 acres and are provided with over 39 miles of quayage.
5. Hamburg, the largest sea port of continental Europe, situated on the Elbe river about 75 miles from its mouth. The port has over 20 miles of quayage for sea-going vessels and a total water area of over 4,100 acres of which about one-half is available for ocean-going ships.
6. View of Rio de Janeiro harbour looking over Botafogo suburb to the bay entrance which lies between the Sugar Loaf (right) and the Pico (left). The entrance is about a mile wide and open to vessels of the largest draught. In 1928 there were over 3 miles of commercial quays in the port.

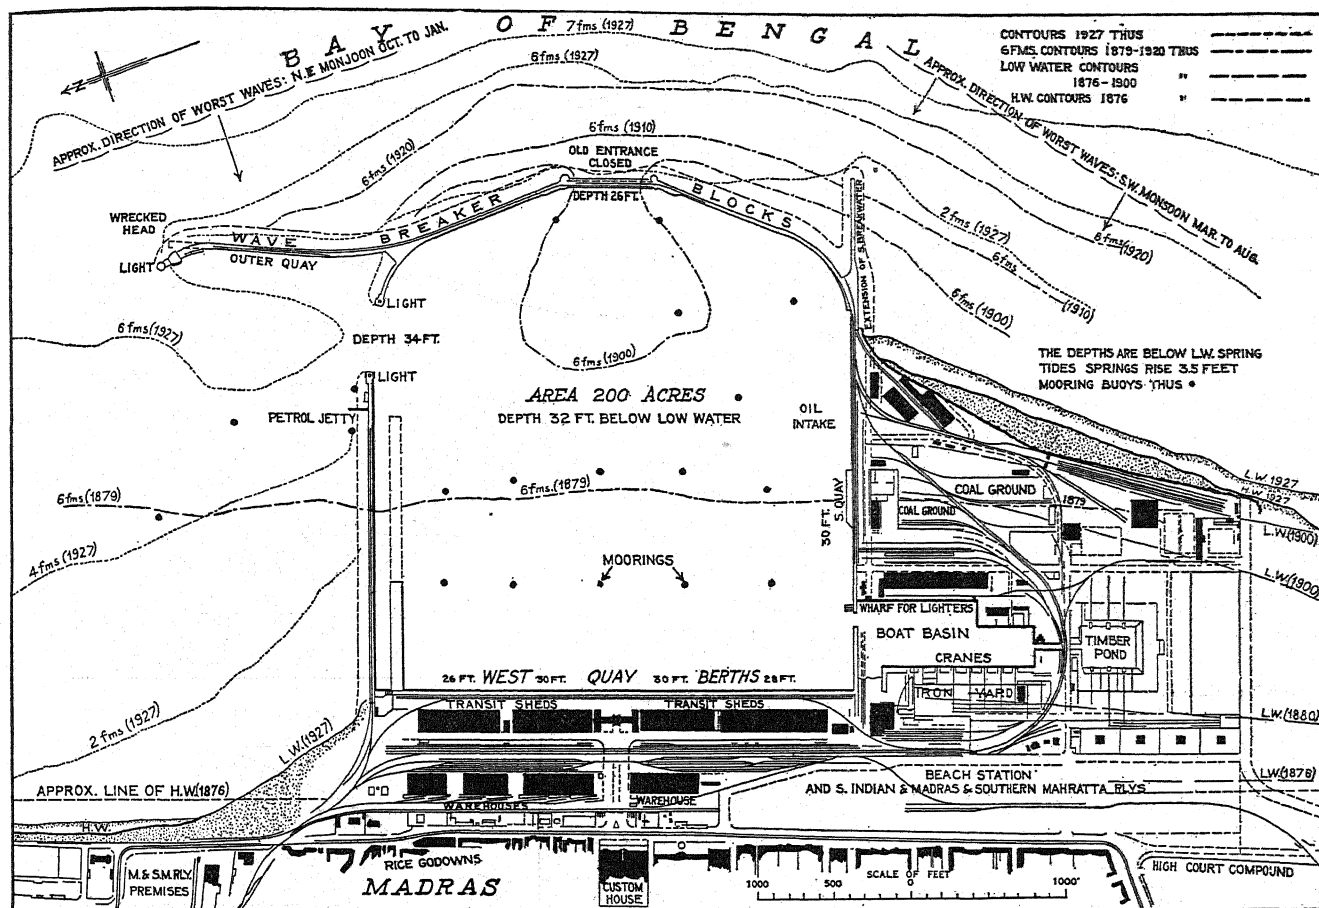

FIG. 2.—MADRAS HARBOUR IN 1927

in the latter. (7) The entrance width to a tidal harbour must not however be so restricted as to produce through the opening a current interfering with safe navigation. (8) The approaches to the entrance from seaward should not be obstructed by submerged dangers in or close to the recognized channel. If there be any such dangers in the vicinity of the harbour entrance they must be removed or, at least, suitably marked. (9) There should be sufficient extra depth of water (over the nominal depth of the harbour) in the approaches and at and near the entrance to allow for the effect of range.

Waves.—The action of waves on solid structures is discussed under BREAKWATER (*q.v.*), and for theories concerning them and their phenomena see WAVES and TIDES; the writings of the authorities mentioned in those articles should also be consulted. Here we will mention one matter closely connected with the selection of harbour sites.

The height of waves largely depends on what is termed the "fetch," that is, the distance from the weather shore, where their formation commences. According to Thomas Stevenson the following empirical formula is nearly correct for waves in the heaviest gales:—Height of wave from trough to crest in feet $= 1.5 \sqrt{d}$, where d is the maximum fetch in nautical miles. This formula presupposes unobstructed deep water, for waves of great height cannot reach any coast line or artificial obstruction unless there is an unbroken stretch of deep water for their propagation. Reefs and sandbanks, even though entirely submerged, materially reduce the range of undulation; and a sudden change in the level of the sea bed, even in comparatively deep water, may produce a breaking wave. Moreover, it seldom happens in the heaviest gales that the wind is blowing for a sufficient length of time from the direction of and along the whole extent of the greatest fetch to bring about the generation of waves of the maximum possible height. The formula therefore gives too high a value when applied to a fetch exceeding about 500 miles. The heights of waves are increased when they are

propagated up funnel shaped or converging channels and are decreased when they pass into expanding channels.

Effect of the Angle of Incidence of Waves.—If the line of the outer face of a harbour work, such as a breakwater, is at right angles to the direction of the waves, the blow delivered by a wave against the solid structure will be at its maximum. When, however, seas strike the face in an oblique direction so as to be deflected towards the breakwater head and harbour entrance, the waves will sweep across the entrance, or wheel round the head, thus causing a turbulent cross sea at the point where vessels enter or leave the harbour. It is an advantage when the face of the breakwater can be aligned so that the heaviest seas assail it obliquely at such an angle that the waves are deflected away from the entrance and towards the inner or shore end of the structure. But in such cases the shore must be adequately protected, naturally or artificially, against scour.

It is a matter of common observation that the direction of waves is sometimes changed on passing a headland and that they will wheel round and enter a bay on the lee side of the head and break on a lee shore. A similar effect is often noticed in the case of islands and it frequently occurs at the head of breakwaters. The phenomenon is no doubt due to the frictional retardation of the inshore portion of the wave in shallow water. The deflection of waves during their passage up a wide channel between two shores is susceptible of similar explanation. Even if the wind is blowing and the waves are travelling up the channel in the direction of the centre line, the waves will be deflected and curve round so as to approach the shore on lines almost parallel with it.

Spending Beaches and Range.—The best method of quickly reducing the height of waves entering a harbour is to secure their lateral expansion. This may be effected by widening the harbour immediately inside the entrance and providing for expending beaches; or by intercepting, by means of spurs, groynes or wave traps, the ends of the entering waves, thus admitting of endwise expansion after the interception has taken place; or by a com-

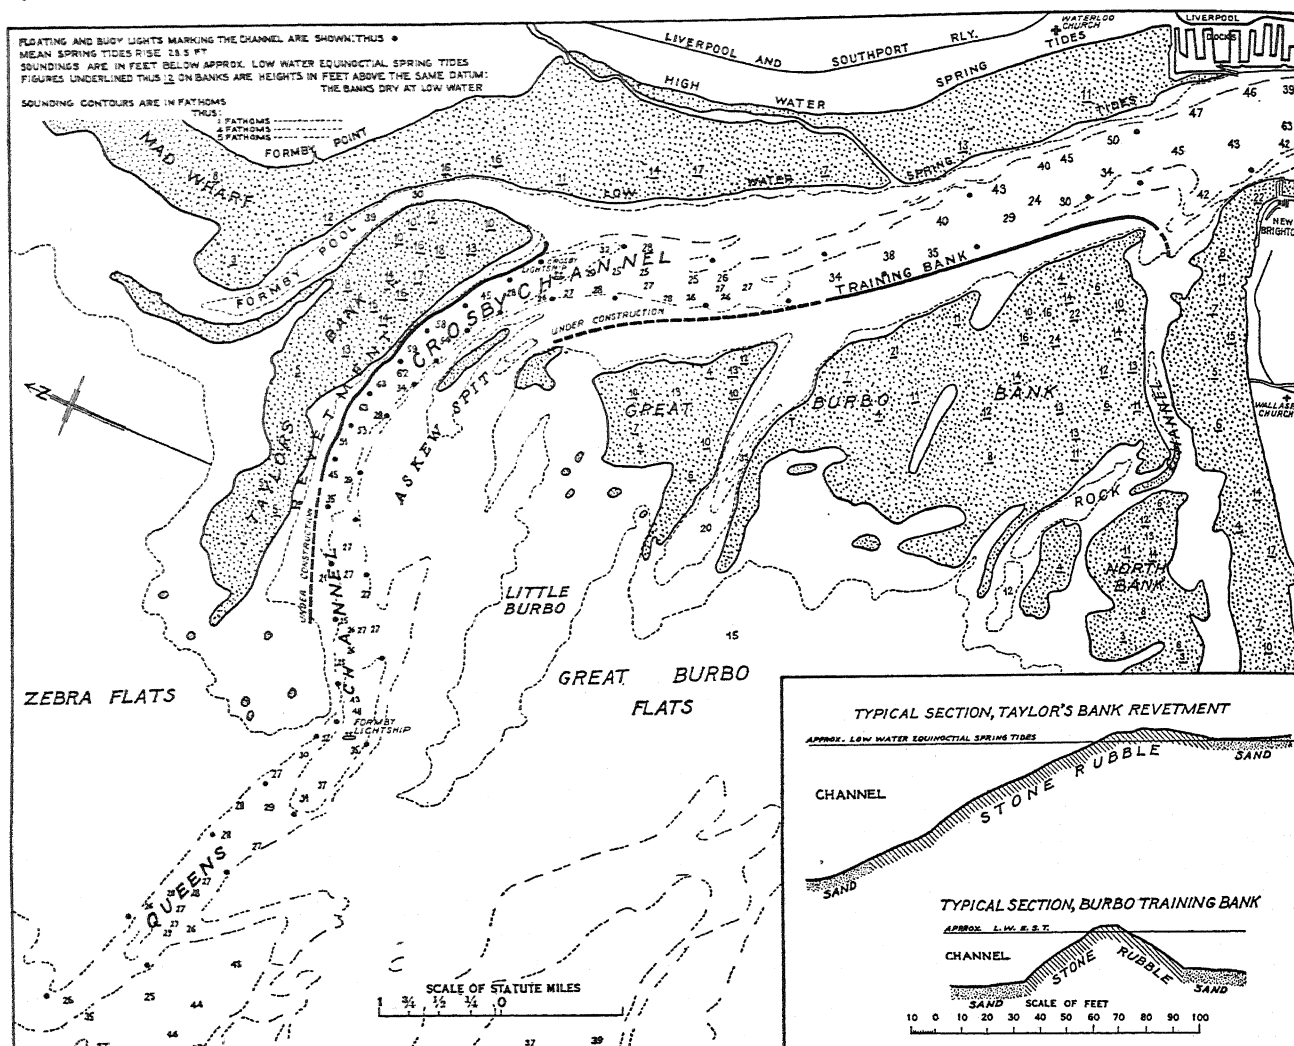

FIG. 3.—LIVERPOOL BAY AND MERSEY ENTRANCE CHANNELS, 1926

bination of these means. (See *Proc. Inst. C.E.* vol. CCIX., 1921.) The first method is the more effective and is to be preferred for harbours whose entrances are exposed to heavy seas. The harbour at the Tyne entrance (fig. 1) illustrates the combined effect of widening within the breakwater heads, expending beaches and wave traps. Waves 30 ft. in height have been observed just outside the entrance during a sustained gale from the north-east. The reduction of range between the pier heads and the Narrows at Shields, a mile inshore, is over 90%. The entrance between the outer pier heads is 1,180 ft., and the greatest width in the outer harbour is about 5,000 feet. The arrangement of breakwaters and spending beaches in the outer harbour at Sunderland, and in that at Ymuiden, is somewhat similar to the Tyne. Wave traps are frequently introduced in the planning of jetty harbours. (See below.)

TYPES OF HARBOURS

Natural Harbours.—A sheltered anchorage in its simplest form is sometimes found under the lee of outlying reefs, sandbanks or islands. Where there is good holding ground and the shelter afforded is sufficient to give protection from heavy seas, such an anchorage is termed a *Roadstead*. Examples are the Downs under the shelter of the Goodwin Sands; Dunkirk road, under the lee of the Braekbank sand; Yarmouth roads and the anchorages in sheltered positions in some wide estuaries such as that of the Thames. Others are found in deep embayments where shelter is afforded from the worst winds by projecting headlands, as in Weymouth and Portland roads. A well-known example of a roadstead protected by an island is that sheltered by the Isle of Wight.

Natural havens to which the term harbour is ordinarily applied are those inlets or arms of the sea which are almost completely land-locked. Where such natural shelter is found combined with ample depth of water, both in the approaches and in the anchorage, and in positions convenient for sea-borne trade, it is of great value to shipping; such havens, even without artificial works, serve as harbours of refuge, and the necessary interior works of a port can usually be constructed in them without difficulty and at much less cost than in an exposed and open situation. Well-known examples in addition to those already mentioned are the harbours of Port Royal and Kingston in Jamaica, Southampton Water, the land-locked sea inlets of San Francisco, Cromarty Firth, Scapa Flow, Milford Haven, Queens-town, Falmouth and Kiel. In many situations, however, there are large enclosed water areas having openings into the sea which are either obstructed by a bar at the entrance, as in the lagoon harbour of Venice and the enclosed bay harbour of Durban, or are shallow. Works of considerable magnitude are often required for the improvement and maintenance of such harbours.

Estuary Harbours and Entrances.—Some rivers which possess sufficient depth of water in the tidal compartment for the navigation of vessels of considerable draught up to the docks or wharves of the port, are obstructed in the estuary, or where they discharge into the open sea, by banks of sand or silt which, sometimes, are liable to change of position. In other estuaries the approach channels from the open sea to the river proper may be sufficient for all the requirements of shipping while the river channels are of insufficient depth.

Not only are such obstructions or "bars" met with in the

estuaries of rivers which discharge into seas that are either tideless or of small tidal range, but they are frequently present when the rise and fall of the tide is considerable, as in the Mersey (fig. 3). Rivers opening out into large expanding estuaries, such as the Severn, Scheldt and Clyde, are usually free from bars; and rivers which gradually widen out as they approach the sea are not ordinarily impeded by bars, though they may be obstructed by sand-banks, as in the Thames and Humber, through which the tidal streams form good channels to the sea. The formation of a navigable channel through a bar, or the improvement of natural channels to provide for the increased draught of vessels, has been effected in a few cases by dredging alone, in some by training works or jetties, and in many cases by a combination of the two methods. The Mersey at Liverpool and the harbour of New York are notable examples of the first case of estuarine conditions embracing the presence of a bar with deep water in the river above it.

The Mersey Entrance.—The inner estuary of the Mersey has a depth in some places of about 63 ft. at low water, but the bar in the principal sea channel of the estuary, in its natural condition up to 1890, had no more than 11 ft. depth over it at low water spring tides, and 32 ft. at high water neap tides. The bar is about 11 m. seaward of the river entrance between Seaforth and New Brighton. Since 1890 the formation and maintenance of a deeper channel through the bar have been problems of great difficulty and dredging by means of powerful sand-pump dredgers, commenced on an experimental scale in that year, has been carried

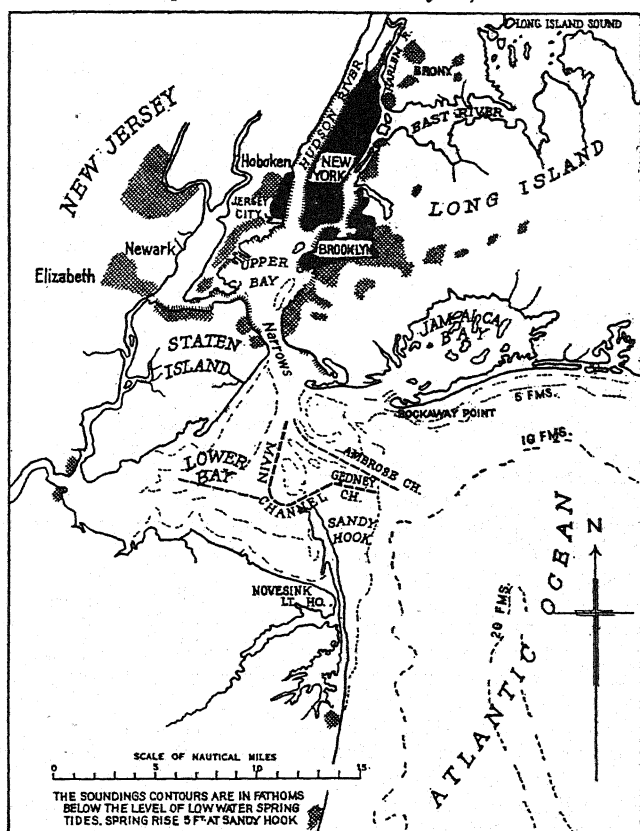

FIG. 4.—NEW YORK HARBOUR

on almost continuously. The quantity of material removed in recent years from the bar and sea channels averages about 20,000,000 tons annually. Since 1907 rubble-stone training walls or submerged revetments, brought up to just above low water, have been constructed, first on the concave east side of the Crosby channel and later on its west side, mainly with the object of fixing the channel and preventing its encroachment on the Taylor's bank (fig. 3). In spite of these training works and intensive dredging the minimum depth in the Mersey approach channels has not been increased beyond the 26 ft. at lowest water available in 1907.

New York Harbour Entrance.—Until 1885 the natural channels in the southern approach to New York harbour sufficed for all the requirements of shipping. The Gedney channel had then a depth of about 24 ft. at low water and about 28 ft. at high water neap tides. Above the sandbanks which obstruct the Lower Bay there is ample natural depth—over 44 ft. at low water—up to the principal piers in the harbour (fig. 4). In 1885 the deepening of the Gedney channel by suction dredging was commenced, and by 1892 30 ft. at low water had been obtained over a channel width of 1,000 ft. Early in the present century an entirely artificial and shorter dredged cut—the Ambrose channel—with a low water depth of 40 ft. and 2,000 ft. wide, was formed through the sand banks. The dredging of the Gedney channel was the earliest successful attempt to maintain an open channel through exposed sandbanks by means of dredging alone. Such attempts had been made, for instance, at the bar at the mouth of the practically tideless Mississippi where, for years before the training works were commenced (see RIVER ENGINEERING) a dredger was employed for forming a channel for the waiting vessels, the channel, however, silting up almost as rapidly as it was made.

Other Instances of Dredging.—Suction dredging has, in recent years, been carried out with success in the course of the improvement of the open sea channels of many estuaries, as for instance, in the Scheldt which gives access to Antwerp; in the Rio de la Plata in the approaches to Buenos Aires and Montevideo, and in the sea approaches to Brisbane (Queensland). The success of dredging operations on a large scale in sandy estuaries has only been made possible by the improvements effected, since about 1890, in the construction of large and powerful sand pump dredgers (*q.v.*). Some of these are capable of raising 10,000 tons of material per hour.

Lagoon and Jetty Harbours.—The formation or improvement of harbours on the sea coast by the construction of jetties across the beach and foreshore, at points where river mouths or lagoons, or, in some cases, low marshy land afforded suitable sites, has been practised for over two hundred years.

Lagoons.—A marine lagoon is a shallow lake separated from the sea by a narrow belt of coast formed of deposit from a deltaic river or of sand dunes heaped up by onshore winds along a sandy shore. Many such lagoons possessing good natural shelter have outlets which are maintained through the fringe of coast, even when the tidal rise is quite small, by the scour of the water flowing into and out of the large expanse at each tide, aided by the discharge from any rivers falling into it. These outlets afford navigable access to the lagoon in which, moreover, natural channels are formed by the action of the currents. Owing to the scour of the issuing current becoming gradually too enfeebled, on entering the open sea, to overcome the heaping up action of the waves along the shore, the sea entrance to a lagoon is however usually obstructed by a bar which tends to form a continuous beach across the opening.

The depth over the bar in front of a lagoon entrance can sometimes be improved by concentrating the current through the outlet by jetties on each side. This has been done with success and, up to a point, without recourse to dredging, in the cases of the three entrances to the lagoon harbour of Venice at Malamocco, Lido and Chioggia, where the tidal range at springs is no more than 3½ ft. (fig. 5). At Malamocco the low-water depth on the bar was increased from 11½ to 31 ft., and at the Lido entrance from 8 to over 22 feet. The two training jetties at Chioggia are not yet completed (1928) but the depth over the bar has already been increased to 20 feet. Since 1921, however, the Lido entrance has been dredged in order to maintain a low-water depth of 24 feet.

Dredging, in combination with the scour induced by jetties constructed since 1909, has provided a deep entrance channel through the bar at Rio Grande do Sul on the south-east coast of Brazil which formerly obstructed the access to a series of deep land-locked lagoons of very large area. On the other hand dredging alone is relied on (1928) to form and maintain a deep channel through the bar which fronts the narrow entrance to a lagoon of great extent and depth at Cochin on the south-west coast of India, and the construction of jetties is not intended.

Jetty Harbours in English Channel, etc.—On the sandy shores of the English Channel and North Sea there are several well-known harbours where, formerly, flat marshy ground, lying below the level of high water and shut off from the beach by dikes or sand-dunes, was connected with the sea by a small creek or river. In their original condition these ports presented some resemblance, although on a very small scale, to lagoons. Such are

FIG. 5.—THE VENETIAN LAGOON

the old harbours of Dieppe, Boulogne, Calais, Dunkirk, Nieuport and Ostend. The influx and efflux of the water from these enclosed, tide-covered areas, through a narrow opening, sufficed to maintain a shallow channel to the sea across the foreshore, deep enough near high-water for vessels of small draught. When the increase in draught necessitated the provision of an improved channel, the scour of the issuing current was concentrated by erecting jetties across the beach. This obstruction to the littoral drift of sand caused an advance of the low-water line as the jetties were carried seaward so that their further extension was eventually abandoned, as occurred at Dunkirk. Moreover, reclamation of the low-lying areas was gradually effected, thus reducing the tidal scour. Sluicing basins were therefore formed into which the tide flowed; the water being shut in at high tide by gates or sluices was released at low water producing a rapid current through the channel. The sluicing current, however, gradually lost its velocity in passing down the channel and was only effective near the basin outlet and down to a moderate depth below low water. The introduction of powerful mechanical dredging appliances and, in particular, the improvement in suc-

tion dredgers led to the substitution of dredging for artificial sluicing (now seldom resorted to), and made it possible to form and maintain channels of uniform depth within the harbour and also, where necessary, seaward of the jetty heads to deep water.

During the past half century jetty construction has been applied with varying success to the improvement of harbour entrances on a much larger scale than in the Channel ports, not only in Europe but in America and other parts of the world, particularly where a river having a considerable flow or an extensive backwater provides the means for effective scour. Instances where scour alone has been effective in securing depths sufficient for large vessels are rare, and dredging has generally to be resorted to for this purpose. It should be noted here that entrances formed by jetties with a narrow channel between them are, from the point of view of the navigator, unsatisfactory in positions of considerable exposure on the open coast, particularly at ports used by large vessels.

Jetty Harbours in N. America.—In the United States there are many examples of jetty harbours. At Charleston (S.C.), for instance, a land-locked bay 15 sq.m. in extent and with ample depth of water, provides an adequate harbour, but the narrow entrance was obstructed by a bar. Converging entrance jetties, each over 2 m. long, with openings at their inner ends, were constructed to concentrate the scour, due to the tidal range of about 5½ ft. at springs, and to protect the channel from littoral drift. The jetties, however, caused an advance of the foreshore and a corresponding progression seaward of the bar with the result that extensive dredging is required to maintain a low-water depth of 32 ft. beyond the ends of the jetties and in the channel. At Aransas Pass (Texas) in the Gulf of Mexico, two jetties have been constructed at the narrow sea entrance to a lagoon or enclosed bay through which a dredged channel, 21 m. long, and 25 ft. deep has been made between the pass and the port of Corpus Christi. In this case also the channel between the jetties has been formed and is maintained entirely by dredging.

Among other jetty entrances to lagoon-type harbours in the Gulf of Mexico, where the tidal range is insignificant, rarely exceeding 1 ft., are those at Sabine Pass, leading to the port of Orange; and in the Bolivar channel at Galveston giving access to Galveston bay and the inland port of Houston. At both of these suction dredging is necessary to maintain depths of from 30 to 35 ft. in the entrances. Two parallel jetties at Tampico, constructed in 1890-92, at the mouth of the Panuco, proved successful in bringing about the scouring of the channel from a depth of 8 to 24 ft. (See *Proc. Inst. C.E.*, vol. cxxv., 1896.)

Lagoons of Coral Formation.—Lagoons of coral formation and waters sheltered by coral reefs often furnish valuable natural harbours as in many of the islands of Oceania; examples are Pango-Pango in the Samoan Islands and Honolulu in the Hawaiian group. In them the problems presented by sandy bars and entrance channels do not as a rule arise. Port Sudan in the Red Sea is an example of a deep-water inlet, bordered by coral reefs rising to just above water level, which has been converted into a useful commercial port by the construction of low quay walls along the margin of the steep-to coral. The entrance is a natural opening 900 ft. in width through the coral reef.

Other Jetty and Bar Harbours.—The physical features of semi-artificial harbours formed in lagoons, backwaters, enclosed bays and at the mouths of barred rivers, differ so much that they exhibit an almost endless variety of works applied to their formation and improvement. A few examples only can be mentioned here.

Hook of Holland.—When the artificial channel for the river Maas was cut, during the 'seventies of the last century, from Rotterdam to the North Sea at the Hook, the sea entrance was flanked by diverging jetties. Rapid silting in the entrance led to the construction of a third and internal jetty to contract the channel to a width of 2,100 ft. and thereby increase the scour. Dredging has, however, to be carried on periodically to maintain the low-water depth of 30 ft.

Durban.—The entrance to the land-locked harbour of Durban (see *Proc. Inst. C.E.*, vol. clxvi., 1906; cxciii., 1914; cxcvi., 1914)

is between two nearly parallel breakwaters or jetties about 600 ft. apart, though the channel is no more than 400 ft. wide (fig. 6). Before 1883, when the first breakwater was begun, the bar at the entrance often shoaled so much that there was sometimes less than 3 ft. of water over it. The constant travel of littoral drift from south to north across the harbour mouth almost completely neutralized the scour induced by the great volume of water flowing

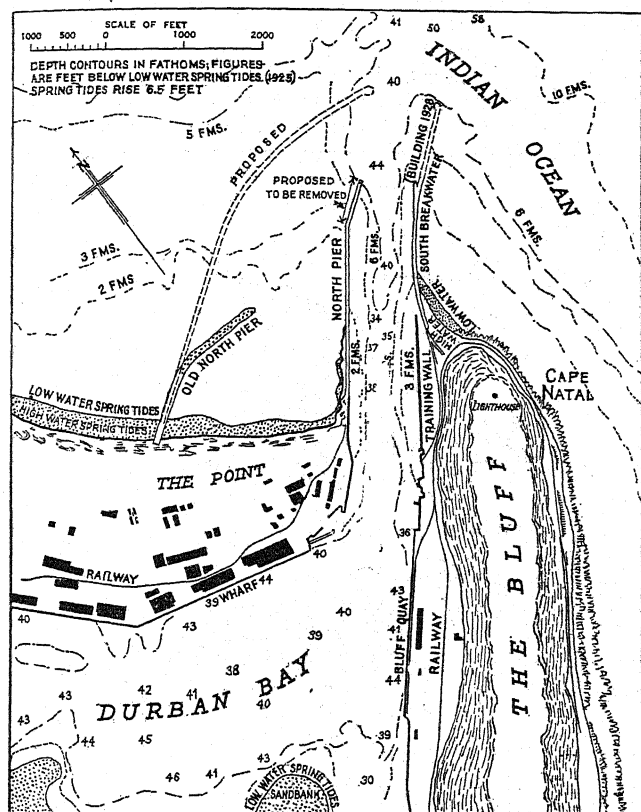

FIG. 6.—DURBAN HARBOUR ENTRANCE

between the piers every tide, into and out of the large land-locked bay; and it was not until intensive suction dredging was employed, about 1896, that the low-water depth in the entrance was increased beyond 16 ft. It has since been steadily improved by continuous dredging until now a depth of about 36 ft. is available. Narrowness of the channel between the jetties, which are in an exposed position open to the Indian Ocean, has always made the entrance a difficult one. The increase in the dimensions of vessels using the harbour has, in recent years, led to demands for an enlarged entrance and steps will, no doubt, in due course be taken to give effect to this want.

Karachi and Vizagapatam.—Karachi, on the coast of Sind, is a natural harbour, with an ample backwater, extensive creeks, and a tidal range of $8\frac{1}{2}$ ft., which has been developed by building entrance jetties and dredging. Somewhat similar natural conditions exist at Vizagapatam (spring rise $4\frac{1}{2}$ ft.), a port halfway between Madras and Calcutta, where there is a tidal creek and backwater of lagoon character with a narrow and shallow entrance in an exposed position on the coast line. For many years various plans for making a deep-water harbour, somewhat after the Madras model and seaward of the creek entrance, have been considered. None of them has been adopted; but deep-water internal port works are (1928) being constructed in the backwater and an interesting and bold attempt is being made to form and maintain, by dredging, a channel of 30 ft. at low water through the narrow entrance and into the backwater, protected by a rubble stone jetty on its northern side only. The construction of a second parallel jetty may be found necessary later.

Lagos, the principal port of Southern Nigeria, has an entrance 1,700 ft. wide, formed by dredging between converging jetties of rubble stone.

Australian Bar Harbours.—The harbour of Newcastle (N.S.W.), the principal coal port of Australia, is in a backwater into which flows the Hunter river. The entrance was obstructed by a sand bar with less than 13 ft. over it at low water. Jetties constructed to shelter and improve the passage over the bar, where the spring rise is 5 ft., had little effect in the latter direction, but since 1905 dredging has increased the depth to about 26 ft., and a moderate amount of sand dredging suffices to maintain the channel depths. The width of channel between the jetties at the entrance, about 1,400 ft., is larger, on account of the exposure, than is usual in jetty harbours. Range in the harbour is considerable and the slight divergence of the jetties tends to increase it. Wavetraps have been formed at the sides of the channel between the jetties.

Fremantle harbour, the principal port of Western Australia, at the mouth of the Swan river, has been made by the removal of a bar of rock and sand which completely blocked the entrance to the river. At the site of this bar and within it there is now a harbour 36 ft. deep at low water protected by jetty breakwaters. The river mouth is sheltered by outlying islands and shoals and the sand travel is not a serious problem.

New Zealand Bar Harbours.—Otago harbour, one of the few New Zealand natural harbours at which improvement works in the entrance have been necessary, is in the South Island. A training mole at the bar entrance, training works in the inner channel and a moderate amount of dredging have been effective in providing a channel with a least depth of 30 ft. at low water where formerly a sandy bar and inner shoals restricted it to about 15 ft. (See *Proc. Inst. C.E.*, vol. cx., 1892; cxxi., 1895; and cc., 1915.) The harbour is a long narrow sea inlet at the head of which, about 11 m. from the entrance, is situated the town of Dunedin.

Westport, on the W. coast of the South Island and the principal coal port of the dominion, furnishes an example of the provision of wave traps (fig. 7) in an entrance between converging training jetties or breakwaters built in 1886–93. The position is one of moderate exposure, the entrance being open to the Pacific. The combined effect of the contracted river and tidal scour and a moderate amount of dredging has increased the low-water depth over the bar from 4 to about 18 ft., the rise of springs being $9\frac{1}{2}$ ft. (See *Proc. Inst. C.E.*, vol. cxii., 1893; cxxxvi., 1899.) For other examples of jetty harbours at river mouths see JETTY and for harbours at river outlets see RIVER ENGINEERING.

Bay Harbours Protected by a Single Breakwater.—The adoption of a deep-water bay for a harbour reduces the necessity for providing artificial shelter and, in most situations, secures a site not exposed to silting, where sheltering works do not inter-

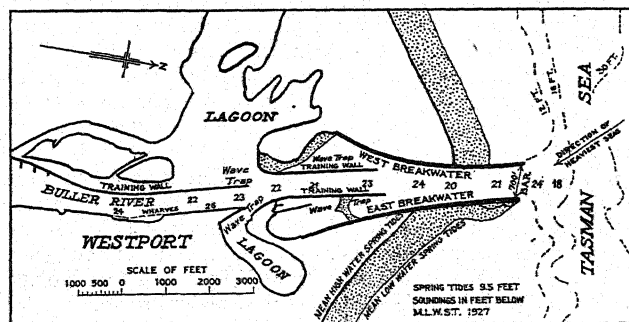

FIG. 7.—WESTPORT HARBOUR, NEW ZEALAND

fere with any littoral drift along the open coast. In favourable situations a deep and narrow bay or inlet may be sheltered by a single breakwater extended out from one shore across the outlet of the bay, having a single entrance between its extremity and the opposite shore. Sometimes—where the exposure is from one direction only approximately parallel with the coast line at the site, and there is some natural shelter in the opposite direction—a single breakwater extending at right angles to the shore, with a bend or curve inwards at its outer end, suffices to afford the necessary shelter. As examples of this form of harbour construction

may be mentioned Newhaven breakwater, protecting, on the west side, the approach to the river port which is somewhat sheltered from the moderate easterly storms by Beachy Head; and Table Bay breakwater, which shelters the harbour from the N.W., protection on the opposite side being afforded by the wide sweep of the coast-line of Table Bay. Other examples are Holyhead, Fishguard, Brixham, Victoria (B.C.), Los Angeles and Valparaíso and

cases the breakwater is bent in plan having two straight arms connected by a curved portion. The sites are somewhat more sheltered than Valparaíso bay and the depths of water considerably less. At both harbours piers and other inner port works are being constructed under the lee of the breakwater.

Table Bay.—The harbour of Cape Town is generally known by the older name of Table Bay. The present rubble mound breakwater dates from 1860; it has been extended seaward several times and at present (1928) 1,500 ft. is being added which will make the total length about 1 m.; the head of the extension, which is of concrete blockwork, will be in a depth of about 46 ft. at low water. The breakwater projects from the W. side of Table Bay in an easterly direction. Under its shelter is an inner harbour

FIG. 8.—PETERHEAD HARBOUR

other harbours on the Chilean coast. The Folkestone harbour pier is an example of a single curved breakwater, sheltering the harbour formed on its E. and N. sides, which also has berths on its outer face. These are used by the cross-channel steamships in heavy weather from the E. or N.E., at which times the inner berths are much exposed.

Fishguard.—The harbour here was made by the building (1900–18) of a breakwater across Fishguard bay. The internal shelter has been increased by the subsequent construction of a second breakwater thrown out from the shore in the middle of the bay. The principal object of this addition was, however, to tranquilize the waters in the berths alongside the steamship quays at the head of the harbour.

Los Angeles Harbour.—An important artificial harbour has been formed here on the Californian coast by building (1898–1910) a breakwater over 2 m. long from the southern arm of San Pedro bay. (See *Proc. Inst. C.E.*, vol. cxv., 1914.) It is one of the few large breakwater harbours in an exposed position on the sea coasts of the United States made to provide outer anchorage of, and the entrance to, a commercial port. The breakwater is curved in plan and extends across the bay in an easterly direction terminating in a depth of 48 ft. at low water. It is of the usual American type comprising a rubble mound and solid superstructure. A large inner harbour, basins and piers have been formed along the shores of the bay and in a lagoon near by at Wilmington (see *Docks*). These are afforded ample shelter by the breakwater (fig. 9). The exposure on the E. is limited by the curving coast line.

Chilean Ports.—The breakwater at Valparaíso (see *BREAKWATER*) is a remarkable structure projecting from the western shore of Valparaíso bay. It will have its termination in a depth of 180 ft. of water. The water area, which will be fully sheltered by the completed breakwater, is small and the cost (reported to be £2,500 per lineal metre for the extension) very large in proportion to the benefit to be derived. (See *Proc. Inst. C.E.*, vol. ccxiv., 1923 and xivth., Int. Nav. Congress, Cairo, 1926, *Proc. Paper* 29 bis.)

Single breakwaters have also been built in the bays of San Antonio (1911–18) and Antofagasta (1918–27). In each of these

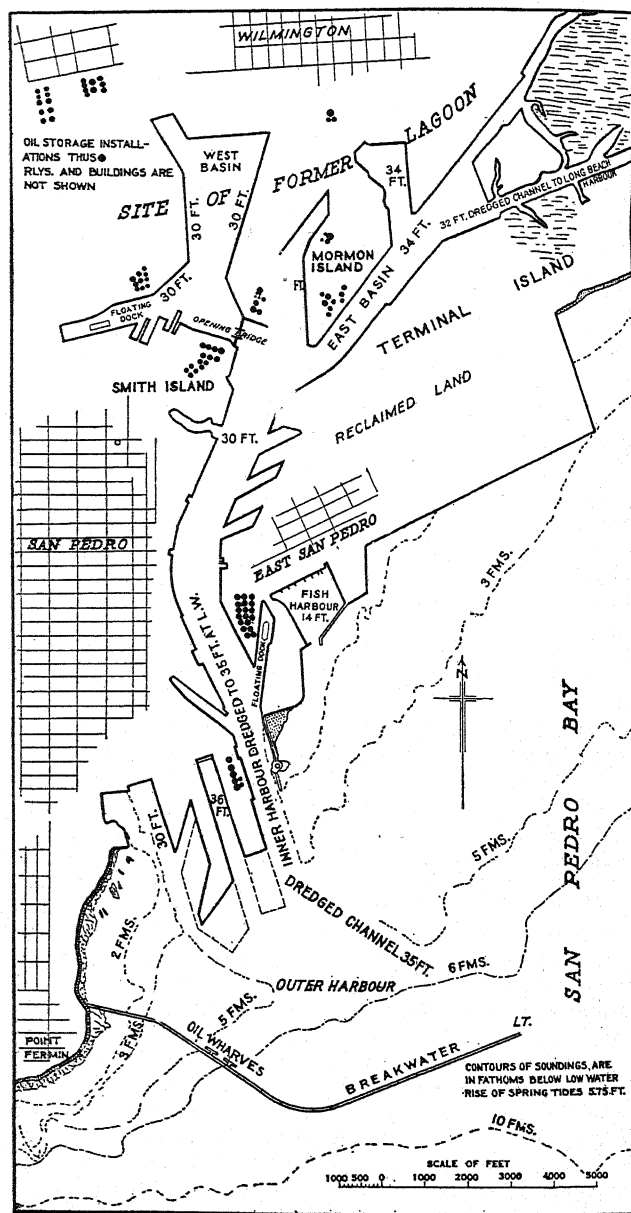

FIG. 9.—LOS ANGELES HARBOUR, 1927

having a water area of 75 acres with quays and jetties; and the building of a new and larger inner harbour farther to the S.E. has been commenced.

Island Breakwaters Protecting Embayments.—In the case of a deep, fairly land-locked bay or inlet of the sea, a detached breakwater across the outlet, leaving an entrance between each extremity and the shore, is sometimes sufficient to give the additional shelter necessary to form a safe harbour and anchorage. This form of protection is usually only practicable when there is deep enough water near the shore, on one or both sides, to afford

ARTIFICIAL HARBOURS AND DEEP WATER RIVER-HARBOURS

1. Table Bay Harbour, Cape Town, the principal passenger and mail port of South Africa. The Victoria basin (left) has an area of 67 acres with a depth of 36 ft. at low water alongside some of its quays
2. Unloading cargo at Alexandria, the chief Egyptian port on the Mediterranean, protected by breakwaters and divided into an inner and outer harbour. A net-work of railways linking it with the interior enables it to handle about 80% of country's overseas trade
3. The water front at Jacksonville, Florida, an important shipping centre on the St. John's river about 23 miles from the sea. The channel of the river is being dredged to 35 ft. depth
4. The water front at Philadelphia, one of the largest American deep water river harbours, as seen from Camden, N.J. Situated on the Delaware

- river 88 nautical miles from the capes of Delaware bay, it has port facilities for accommodating 100 deep draft steamships at once
5. Bremen, the second port of Germany, situated on the river Weser, 40 miles above Bremerhaven and about 58 miles from the open sea. The river harbour possesses about 18.5 miles of quays and wharves. The river navigation is kept open in winter by ice-breakers
6. The harbour of Hongkong, China, looking towards the mainland. Part of the residence section is shown in the right foreground and a portion of the business district may be seen at the left nearer the water-front. The port accommodates ships of all sizes in practically unlimited numbers

NATURAL AND ARTIFICIAL HARBOURS OF EUROPE AND AMERICA

1. View of the waterfront at Gothenburg (Göteborg), the first port in Sweden, situated on the river Göta about five miles from the Catte-gat. The harbour has been recently enlarged and is now the principal port of embarkation for Swedish emigrants to America
2. Boston harbour as seen from the Customs House tower, looking toward East Boston. The wharfrage extends for 8 miles with a berthing space of 40 miles. The main ship channel is 35 feet deep at low water, enabling the port to accommodate the largest vessels afloat
3. Aerial view of Constantinople, showing its harbour, the Golden Horn, an inlet of the Bosphorus about 4 miles long. It is divided by Galata Bridge into an outer harbour and an inner harbour and naval port
4. View of Marseilles on the Mediterranean coast of France, showing the

Bassin de La Joliette, part of the great range of basins enclosed by the breakwater (background) which extends for more than $3\frac{1}{2}$ miles parallel with the coast. In the foreground (left) is Fort St. Jean

5. General view of Naples, the second port of Italy. The harbour, overshadowed by Mount Vesuvius, reaches across the bay from west to east for a distance of 2 miles and is protected by breakwaters. It has a depth ranging from 30 to 35 feet
6. View of the inner harbour of Los Angeles showing Terminal Island (left), Mormon Island and Wilmington (background) and Smith Island (right). The channel has been dredged to a depth of 35 feet, the East Basin (right) to 34 feet and the West Basin (left) to 30 feet

suitable entrance.

Plymouth.—The best known example is the breakwater affording the artificial protection necessary to convert the natural harbour of Plymouth into a place of almost perfect shelter. Plymouth Sound, one of the most famous and historic roadsteads of the world, and the deep inlets or creeks above it form a harbour into which fall the rivers Tamar and Plym. The breakwater is 1 m. in

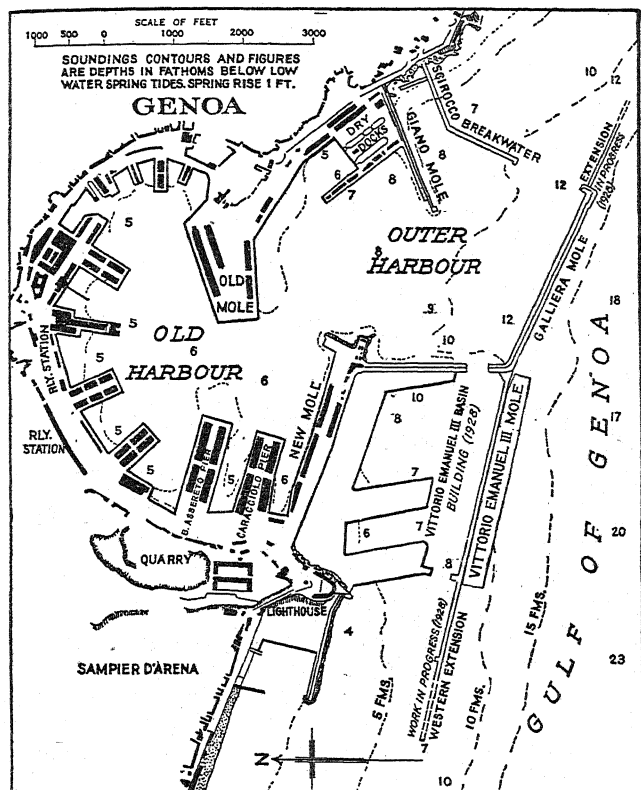

FIG. 10.—GENOA HARBOUR

length stretching across the middle part of the sound. Begun by John Rennie in 1812, it was completed about 1827. In the harbour itself are the naval dockyard establishments at Devonport and Keyham, and small commercial dock and port works at Millbay and in the Cattewater.

Cherbourg.—The breakwater across the wider but shallower bay forming Cherbourg harbour and roadstead is another example of an island structure but in a more open and exposed position than Plymouth. Begun in 1784, its construction was continued under Napoleon, but it was not completed until 1858. Over 2½ m. in length it is built, for the most part, in a depth of about 42 ft. at low water. It is of composite construction, a solid superstructure surmounting a rubble stone mound. The sheltered water area is over 2,000 acres in extent, but not more than one quarter of this is of sufficient depth for large vessels. The two entrances on the E. and W. are between the breakwater ends and islands which are themselves joined to the mainland by breakwater walls.

Delaware Bay.—The Delaware breakwaters at Cape Henlopen, the S. horn of the entrance to Delaware Bay, are both of the island type. The first, built (1828–69) inshore under the shelter of the headland, is the prototype of American rubble-mound breakwaters. The national harbour of refuge of about 800 acres formed outside the old breakwater by the U.S. Government (1897–1901) is protected by a rubble-mound breakwater 8,040 ft. in length built in a depth at low water of about 30 ft.

Another American island breakwater of the mound type, commenced in 1884 with the object of forming a harbour of refuge in Sandy Bay near Rockport (Mass.), has had a disastrous history of storm damage and the work is still unfinished. The position is one of great exposure for which the rubble-mound type is unsuited.

Island breakwaters frequently form portions of the artificial protection of harbours in conjunction with breakwaters projected

from the shore line. Some examples of this combination are referred to hereunder.

Bay Harbours with Two or More Breakwaters.—The method most generally adopted for the completion of the shelter of deeply indented bay harbours is the construction of a breakwater extended across the outlet from each shore, leaving a single entrance between their ends, where usually the deepest water is found as at Peterhead and Monaco. If one breakwater placed somewhat farther out is made to overlap an inner one, and so cover it to some extent from the direction of the heaviest seas, a more sheltered entrance is sometimes obtained. This arrangement was adopted when additional protection works were built at the entrance to the old bay harbour at Genoa (fig. 10) and for the harbour in Bilbao bay at the mouth of the Nervion. The breakwaters at Valetta (Malta) and those at the entrance to the almost land-locked Spanish naval harbour at Cartagena are also planned in this way. Many harbours formed in wide or open bays, and in other positions where some abrupt projection from the coast line has been utilized as providing shelter from one quarter, have their protection completed by two or more breakwaters enclosing the site. Dover (fig. 11) and Colombo (fig. 12) furnish typical and somewhat similar examples. Both of these were begun as single breakwater harbours, and their conversion into enclosed harbours was not completed until many years later.

The extension of artificial shelter has often been brought about not only by the demand for more complete protection against heavy seas and consequent range in a harbour, but also by the growth in the dimensions of ships and the increase in the trade of a port. Thus, greater depth of water and extended accommodation have been obtained at one and the same time with the improvement of the shelter by building additional breakwaters.

In some instances a wide or exposed entrance to a harbour formed by breakwaters thrown out from the shore has been sheltered by an island breakwater built in front of the opening and thus providing two entrances, one at each end of the island structure; Bizerta (Tunis), and Cette furnish examples. In other cases, as at Dover, Portland and Colombo, the line of breakwaters enclosing the harbour has been made discontinuous, two, and in some cases more, openings being formed between them. The Gibraltar harbour works (1893–1904), made in the sheltered bay of Algeciras on the W. of the Rock, include a detached mole with two entrances between it and the breakwaters which are connected with the shore.

Dover.—This is an example of an artificial harbour formed on a coast of moderate exposure—the narrowest part of the Straits of Dover. The nucleus of the harbour which exists to-day was the

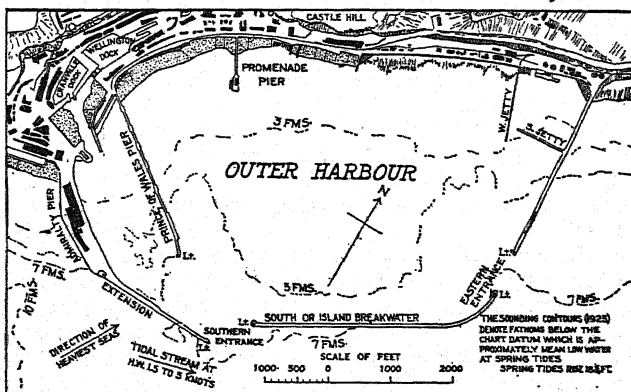

FIG. 11.—DOVER HARBOUR

Admiralty pier, commenced in 1844 and extended to form the western arm of the outer harbour. The pier afforded shelter from the S. and W., and protection from the N. is given by the coast line and was increased later by the building of the Prince of Wales pier. The works carried out between 1897 and 1909 enclose a low-water area of 690 acres and comprise, in addition to the Admiralty pier, now 4,000 ft. long, an island breakwater of 4,212 ft. and an eastern arm of 2,942 ft. connected with the shore (see BREAKWATER). The harbour was handed over by the Admiralty to the Dover Harbour Board in 1923 for commercial use, and it is

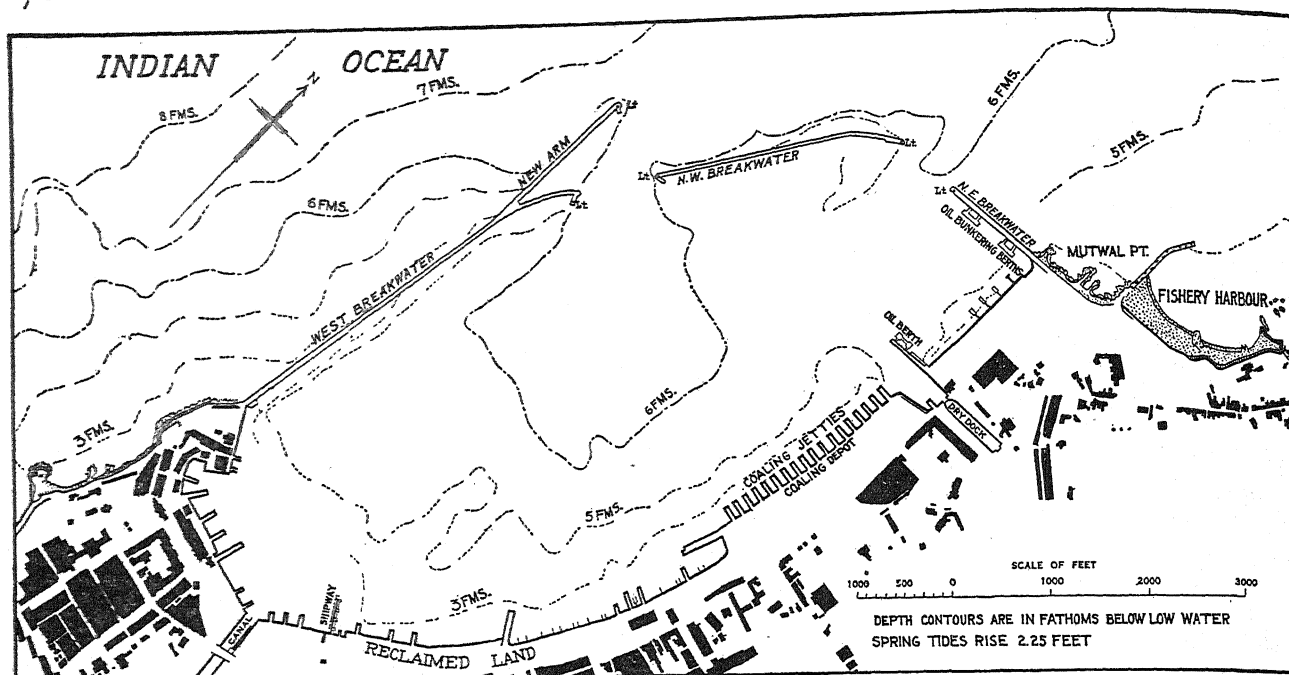

FIG. 12.—COLOMBO HARBOUR, CEYLON

now (1928) proposed, with the object of reducing the severe range in the harbour, to close the western entrance (740 ft.), leaving only the eastern opening (650 ft.) available for shipping.

Portland.—The refuge and Admiralty harbour of Portland furnishes an instance of the conversion of a naturally sheltered roadstead into an enclosed harbour by the construction of breakwaters projecting from the horns of a bay. The Isle of Portland—actually a peninsula joined to the mainland of Dorset by the Chesil Bank—shelters the roads from the S. and the anchorage is exposed to storms only from E. to S. The southern, or inner, and the eastern, or outer, breakwaters were begun in 1849 and completed in 1872, the latter being in 8 to 10 fm. at low-water. Later two additional breakwaters were added, one projecting from the Bincleave rocks near Weymouth on the N. side, and the other, an island structure, on the N.E. of the harbour. The last was finished in 1904, the building of the later breakwaters being carried out, partly at any rate, as a protection against torpedo attack. There are three entrances between the four breakwaters; but one of them, the southern, was closed in 1914 by sinking a block-ship in it, and it is not proposed to re-open it. The breakwaters have a total length of $3\frac{1}{2}$ m. and shelter a water area of 4 sq.m. Portland is one of the largest artificially enclosed harbours in existence.

Colombo.—The artificial harbour at Colombo (fig. 12), begun in 1875, occupies an exposed situation in an embayment on the W. coast of Ceylon. The site is sheltered to some extent from southerly winds and to a lesser degree from the N. The breakwaters are fully exposed to westerly gales from the Indian Ocean. The S.W. breakwater, the first to be constructed, is 4,212 ft. long and was completed in 1885 (*see* BREAKWATER). Two additional breakwaters, the N.W. and N.E., 2,670 ft. and 1,080 ft. respectively, were built between 1892 and 1906, thus completing the enclosure of the harbour except for two openings of 800 and 700 ft. respectively. The shelter afforded was still insufficient to tranquilize the northern part of the water area, where are situated most of the coaling and oil berths, during the S.W. monsoon. Consequently a sheltering arm, 1,800 ft. in length, was completed in 1912 as an extension of the original S.W. breakwater. The harbour has a water area of 643 acres at low-water; there is a low-water depth of 36 ft. or more, and the harbour has been deepened from time to time to keep pace with the increased draught of vessels. The western entrance has a depth of 40 ft. at low water.

Peterhead.—The shelter afforded by the original single breakwater of the national harbour of refuge at Peterhead is now (1928)

being supplemented by a second and shorter breakwater built out from the northern horn of the bay for a distance of 1,500 ft., thus reducing the width of entrance to about 700 ft. (fig. 8). The two breakwaters will enclose an area of about 280 acres at low tide. The S. breakwater (2,850 ft.), built mainly by convict labour, was commenced by Sir John Coode in 1888 and completed in 1912. Its end is in 55 ft. of water at low tide. The northern breakwater was not begun until 1912, although it formed a part of the original design. These works are exposed to severe storms from the N. and E. and are called upon to withstand a wave impact as great as any assailing harbour structures in Europe.

Havre.—The outer harbour at Havre furnishes an example of a port, originally formed in a sheltered embayment along the margin of an estuary, where it has been necessary to build long breakwaters extended into more exposed waters, in order to provide the additional accommodation demanded by its increasing trade. The modern deep-water quays in the tidal outer-harbour are situated on areas which have been reclaimed from the sea under the shelter of the breakwater walls.

Artificial Harbours on Open Coasts.—It sometimes happens that harbours have to be constructed where little or no natural shelter exists. When, in such cases, the only possible site is an open sandy shore, considerable littoral drift may occur. Breakwaters, carried out from the shore at some distance apart, and converging to a central entrance of suitable width, provide the requisite shelter. Such works may be necessary, not only on open unindented coasts, but also to afford increased shelter at a river mouth on an unprotected coast line. Harbours of this description have, for instance, been made at Madras and Ymuiden on open shores; whilst the breakwaters at the mouth of the Tyne, and those at Sunderland, furnish examples of the protection of river entrances.

If there is little littoral drift from the most exposed quarter, the amount of sand brought into the harbour during storms can be readily removed by dredging. The quantity is, moreover, smaller in proportion to the depth into which the entrance is carried; and the scour across the projecting ends of the breakwaters tends, in some cases, to keep the outlet free from deposit. If a river discharges into the harbour the detritus and matter in suspension brought down by it must also be taken into consideration.

Where there is littoral drift in both directions on an open sandy coast, due to winds blowing alternately from opposite quarters, sand accumulates in the sheltered angles outside the harbour on both sides at the junction of the breakwater with the shore line.

This has occurred at Ymuiden. Silting also frequently occurs just inside the breakwater heads under the shelter of the arms. The worst results occur when the littoral drift is mainly in one direction, so that the projection of a solid breakwater out from the shore causes a very large accretion on the side facing the exposed quarter, whilst, owing to the arrest of the travel of sand, erosion of the beach occurs beyond the lee breakwater (*see COAST PROTECTION*). Such effects have been produced by the works at Port Saïd and Madras. The harbour of Salina Cruz on the Pacific coast of the Isthmus of Tehuantepec, where two breakwaters projecting from the shore were built (1900-6), rapidly sanded up and narrow channels to the berths are only maintained by constant dredging.

Madras and Ymuiden Harbours.—Considering first of all harbours formed by converging breakwaters on an open unindented coast, the two examples mentioned above are both typical and instructive. Madras furnishes an instance of difficulties and unforeseen happenings overcome by continuous effort and drastic modification of the original plans. At Ymuiden the original forecast of the designers has been more nearly, but not entirely, realized. The harbour of Madras, begun in 1877, comprised, when first completed, two breakwaters 3,000 ft. apart carried straight out to sea at right angles to the shore for 3,000 ft. with two return arms inclined slightly to seaward. The breakwaters originally enclosed an area of 220 acres and left a central entrance, 515 ft. wide, facing the Indian ocean in a depth of about 8 fm. The position and form of this entrance were determined mainly on navigational grounds as suitable to the needs of the sailing vessels, still at that time largely employed in the eastern trade. The breakwaters, in a position of extreme exposure on an open coast without any natural shelter, have suffered severe damage from the sea on many occasions necessitating rebuilding from time to time. The great drift of sand from S. to N. resulted in an advance of the shore against the outside of the S. breakwater as it was projected seaward (fig. 2), and erosion, but to a lesser extent, occurred beyond the N. breakwater. The progress of the foreshore in course of time extended so far seawards as to produce shoaling at the entrance; so rapidly in fact that in the ten years from 1893 the depth was diminished by 10 ft. Moreover, the original entrance, facing east, was exposed to the full force of waves during both the N.E. and the S.W. monsoons. At these seasons the range within the harbour was severe and at times vessels could not ride at moorings in safety. A new entrance was therefore constructed by forming an opening in the breakwater on the N. side of the harbour, protected by a sheltering arm, the original eastern entrance being closed when the new entrance had been made (1906-11). The harbour is now comparatively tranquil and vessels are able at all times to lie at the quays in safety.

The advance of the shore line seawards on the S. side of the harbour still appears to average over 25 ft. a year, but the rate of progression tends to decrease as the sand deposit extends into deeper water. The drift of sand along the outside face of the eastern breakwater wall has been checked, at any rate temporarily, by the construction of an extension seaward of the S. breakwater 700 ft. in length which was begun in 1924. This spur breakwater or groyne is protected by concrete blocks placed pell mell on each side. Incidentally the accretion of sand on the S. side of the harbour is not an unmixed evil for the value of the land so formed is increasing with the expansion of the city and much of it has been sold for over £3,000 per acre. Since the tranquilizing of the water area in 1911, the quay accommodation has been largely increased (*see Proc. Inst. C.E., Passim*).

The harbour at Ymuiden, constructed during the 'seventies of the last century, is an entirely artificial one formed, on the open sandy shore and bed of the North Sea, to serve as the entrance to the Amsterdam ship canal. The breakwaters, each about a mile in length, are converging and the entrance faces W. A dredged channel extends from deep water outside the breakwaters to the canal locks. This channel is (1928) being deepened to 40 ft. below mean sea level (spring rise, 5½ ft.). The actual entrance to the canal channel is between parallel jetties built on

the original foreshore where the cut through the sand dunes was first made. The entrance between the breakwater heads is about 800 ft. in width, the harbour widening to 3,800 ft. at the shore line, thus providing broad expending beaches on either side of the canal entrance. The construction of the large entrance lock (1928) (*see CANALS and DOCKS*) has necessitated the sacrifice of a part of the northern spending beach to the formation of an additional and wider canal entrance. In order to compensate for this loss the inner portion of the N. breakwater is being reconstructed so as to form a large wave trap on the N. side of the new channel jetties. The advance of the shore on both sides of the harbour at Ymuiden appears to have reached its limit only a short distance out from the old shore line on each side. The only evidence of drift consists in the advance seawards of the line of soundings alongside, and in the considerable amount of sand which enters the harbour and has to be removed by bucket dredging. For dredging outside the breakwaters suction dredgers are employed. A condition of balance has now been reached. Dredging operations, fairly uniform and continuous in amount (about 1,700,000 c.yd. per annum), but not economically burdensome in proportion to the commercial importance of the harbour, serve to maintain the required depths of water. It is interesting to note here that an early instance of the employment of sand-pump dredgers was in connection with the construction of the harbour by British engineers about 1874 (*see Proc. Inst. C.E., vol. lxii., 1880*).

Port Saïd Harbour, at the Mediterranean entrance of the Suez canal, is interesting as an example of the successful formation of an artificial harbour on an open shore where the littoral drift is almost wholly in one direction. The exposure is moderate and the sea bed slopes very slowly towards deep water. Owing to the prevalence of N.W. winds, the drift is from W. to E., and is augmented by the alluvium issuing from the Nile. The original harbour was formed by two converging breakwaters or jetties, of which the western has been extended seaward from time to time as successive deepening of the canal were effected. Its total length in 1927 was 6,565 yd. and its termination in a depth of water of 38 ft. (*see E. Quellenec, Breakwaters of Egyptian Harbours*, Paper 31 bis., and P. Solente, Paper 54; xiv. Int. Congress of Navigation, Cairo, 1926). The outer portion is a submerged mound serving merely to prevent sand and silt from entering the dredged channel except around the seaward extremity; a further extension was being made in 1928. The E. breakwater, on the less exposed side, is 2,625 yd. long (fig. 13). The shore has advanced considerably against the outer face of the W. breakwater and at the same time erosion has taken place on the E. side of the E. breakwater. The advance on the western side between 1858 and 1926 was 2,750 ft., but the rate of progress has been decreased in recent years as a result of the deeper water to be filled by the sand deposit. Though the progress seawards of the lines of soundings close to the harbour continues a depth of about 40 ft. below normal low water is maintained without difficulty by the continuous working of powerful bucket dredgers in the channel and outer approaches.

The Tyne and Sunderland.—The breakwaters at the mouths of the Tyne and Wear furnish outstanding instances of the successful adoption of the converging plan in situations where a river outfalls on an exposed coast line and there is no protecting estuary or sheltered sea inlet (*see Proc. Inst. C.E., vol. clxxv., 1910 and cclx., 1921*). In the case of the Tyne sand travel has occasioned no difficulty, neither has erosion taken place on the lee side of the harbour, a small rocky headland less than a mile S. forming a natural groyne which has trapped sand and shingle in the embayment between it and the S. pier. At Sunderland some accumulation, though not to a serious extent, has occurred on the N. side of the harbour works and erosion of the foreshore to the S. has necessitated the carrying out of costly protection works. The building of the Tyne breakwaters (fig. 1) was commenced in 1855; they were originally designed to terminate in a depth of 15 ft. at low water, but when more than half finished it was decided to extend them seaward to near the 6 fathom contour. This involved changes in the plan of the harbour and accounts

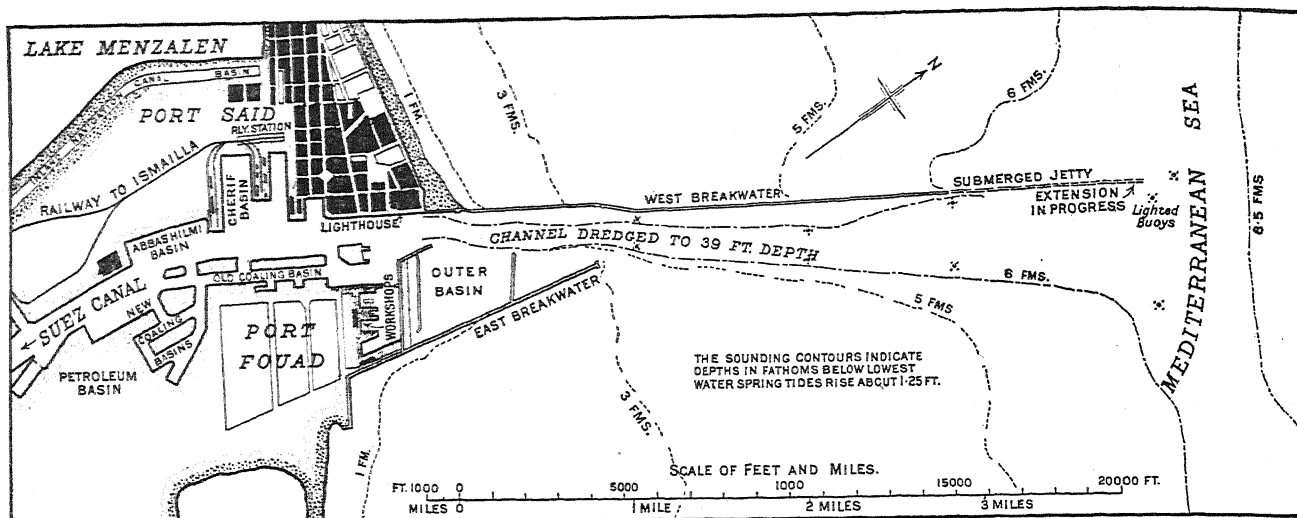

FIG. 13.—PORT SAID HARBOUR AND SUEZ CANAL ENTRANCE

for the somewhat peculiar curved form of the S. pier. The N. pier was originally completed in a similar manner but the outer portion was partially destroyed (1895-6) and subsequently rebuilt on a straight line (see BREAKWATER).

The formation of the outer harbour at Tynemouth has provided a safe deep-water approach to the river whose mouth was, about the middle of the last century, obstructed by a sand bar with no more than 5 ft. depth at low water and was, moreover, notorious on account of the difficulty of entrance and the frequency of wrecks. The channel from the harbour to the docks is dredged to 30 ft. at low water spring tides (see RIVER ENGINEERING).

Casablanca.—A recent example of harbour construction carried out on a large scale on an exposed shore is the making of this artificial port on the Atlantic, the largest and most important harbour in French Morocco (fig. 14). The construction of a small inshore harbour and jetty was commenced in 1907; the sheltering harbour enclosing about 350 acres, for the most part having a depth of 30 ft. or more at L.W., was begun in 1913, and the main

of the harbour is in some ways similar to that of Casablanca, the main breakwater affording shelter on the side exposed to the prevailing winds and heaviest seas, while a transverse breakwater built under its lee has wharves constructed along its side, and the deep water entrance between the breakwater heads is well sheltered. The site selected for the harbour is on an open coast, but is free from the trouble of littoral drift.

Boulogne.—The old harbour of Boulogne is of the conventional jetty type common to the French and Belgian ports of the English Channel and North Sea. The formation of a large outer harbour sheltered by breakwaters projected from the shore was commenced as far back as the 'eighties of the last century. The S. or Carnot breakwater has now been built to a length of about 8,300 ft. but the N. breakwater has not yet been begun. When completed, the enclosed low-water area will be over $1\frac{1}{2}$ sq.m. and the entrance will be in 36 ft. depth at low-water. The Carnot breakwater is T shaped in plan; its shore end is over 6,000 ft. S. of the jetty entrance to the inner harbour, the intervening foreshore forming an ample expending beach. Boulogne harbour is not free from the troubles arising from littoral drift. The sand travel along the shore from south to north has already led to considerable accretion along the outer face of the Carnot breakwater and the depth contours are being gradually pushed seaward.

Breakwaters Connected with the Shore by an Open Viaduct.—Proposals have been brought forward from time to time to evade the advance of the foreshore against a solid obstacle by extending an open viaduct across the zone of littoral drift inshore, and forming a closed harbour, or a sheltering breakwater against which vessels can lie, farther seaward and beyond the influence of accretion. It should, however, be pointed out that the single curved arm breakwater can afford adequate protection only in situations of moderate exposure and where the harbour is naturally sheltered on its open side.

Zeebrugge Harbour.—This principle was carried out on a fairly large scale at the port of call formed by the sheltering breakwater constructed (1900-9) in front of the entrance to the Bruges ship canal at Zeebrugge on the sandy North Sea coast. A solid breakwater, provided with a wide quay furnished with sidings and sheds, and curving round towards the E. so as to overlap the entrance to the canal and shelter an ample water-area, is approached by an open steel and iron viaduct extending out 1,000 ft. from low water into a depth of 20 ft. The solid breakwater is carried out into a depth of 33 ft. at L.W. near the head. It was hoped that by thus avoiding interference with the littoral drift close to the shore, coming mainly from the W., the accumulation of silt and sand to the W. of the harbour, and also in the harbour itself, would be prevented, or at any rate reduced to a very moderate amount. These hopes have not, however, been realized, and considerable dredging is necessary in the harbour and at the entrance to the canal in order to maintain the required depths. The prob-

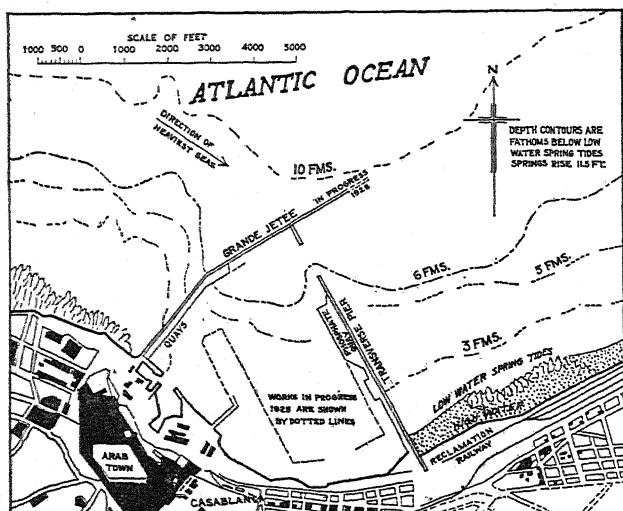

FIG. 14.—CASABLANCA HARBOUR

works completed in 1927. The N. and more exposed breakwater is now (1928) being extended to a total length of 7,215 ft. The works are fully exposed to the Atlantic swell and there is little natural protection, but extensive and well equipped quays are provided alongside the transverse breakwater.

Takoradi.—The artificial deep water harbour of Takoradi, on the Gold Coast (constructed 1921-28), affords an instance of advantage being taken of a rocky reef extending out from the shore to form the foundation for a large part of the main protecting breakwater, which is of the rubble mound type. The plan

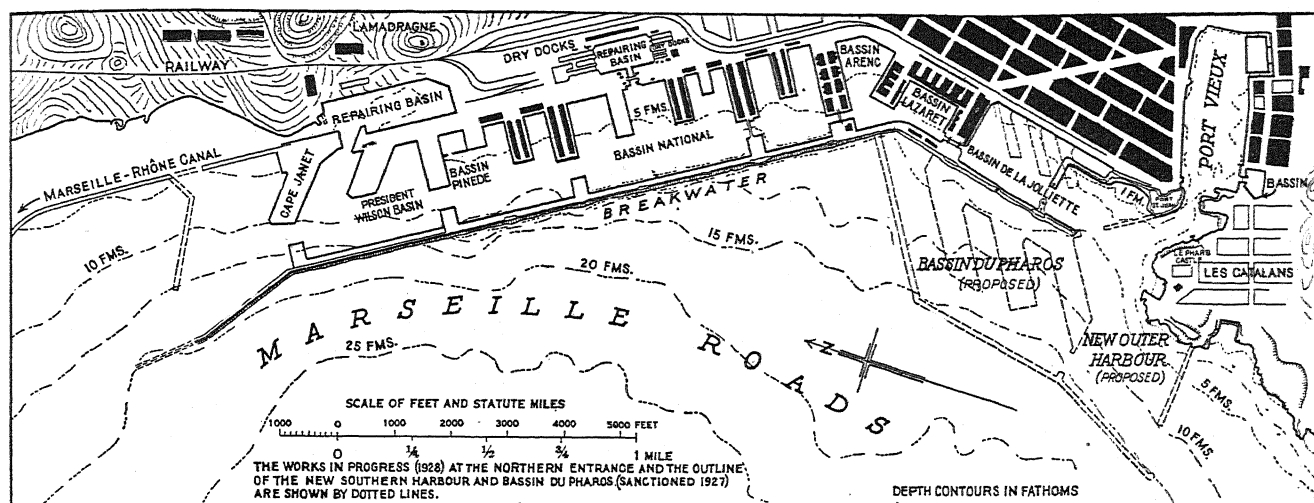

FIG. 15.—PORT OF MARSEILLE

able explanation of the failure to avoid the troubles of sand accretion and silting is, in this as in other similar cases where the accretion has been still more serious, that the shelter caused by anything in the nature of an island near the shore must result in interference with the natural littoral current and drift and consequent stoppage of the travelling material.

Cearà and Rosslare.—A plan somewhat similar to that adopted later at Zeebrugge was carried into effect at Cearà on the N.E. coast of Brazil about 1886. Sand accumulated very rapidly, both inside and outside the harbour; in a few years the low water line had receded as far as the breakwater head and the harbour was ultimately abandoned (see *Proc. Inst. C.E.*, vol. clvi, 1904). Rosslare harbour, near Wexford, on the S.E. coast of Ireland, is another and more favourable example of this type of construction. Here also, however, dredging has to be carried on periodically to maintain the requisite depths for the safe passage of vessels.

Port Elizabeth.—The protected harbour which, after years of preliminary discussion, is now being made in the waters of the wide Algoa bay at Port Elizabeth, will eventually enclose about 680 acres between two curved breakwaters. The eastern or outer arm was begun in 1922 and will afford shelter from S.E. and E. winds and the heavy seas from that quarter. It starts from the head of the Dom Pedro jetty, a steel openwork structure, 1,400 ft. long, dating from the period of the second Boer war, in about 25 ft. at low-water and will terminate in a depth of about 45 ft. This plan has been adopted with the object of leaving open the space covered by the jetty to allow the current to sweep through and in the hope that this will prevent the sand from silting the harbour or accumulating outside as has happened at Madras. The outer breakwater will be, when completed, about $1\frac{1}{2}$ m. in length, and is being built of sloping blocks of stone. The building of the north arm, 8,000 ft. long (not begun in 1930) will form an enclosed harbour within which reclamations of land and construction of jetties are proposed. (See BREAKWATER.)

Harbours Sheltered by Works Parallel to Coast.—Many important modern harbours of artificial construction in the Mediterranean and other tideless seas have been formed by building sheltering breakwaters in deep water at some distance from the shore and more or less parallel with it, leaving openings at one or both ends, or at intervals. Under the shelter of these breakwaters inner port works have been constructed (see DOCKS). This characteristic of Mediterranean harbours is due, first of all, to the absence of good river harbours; for in tideless seas the rivers are usually barred by deltas at their outlets, as the Rhone and Tiber. Secondly, many ancient ports were formed in narrow sheltered sea-inlets as, for instance, the old harbour of Marseilles; or in small bays as at Genoa, Naples and Trieste. In course of time the maritime commerce of such ports outgrew the limited resources of the old harbours and it became necessary to provide enlarged accommodation near by and in deeper water. The only

sites available for such extensions have usually been in more open and exposed situations in deep water fronting the adjacent coast line. Moreover, the great depths of water near the shore at many Mediterranean ports, as for example, Marseille and Naples, make lateral extensions more economical and practically convenient than seaward enlargements.

Marseille.—The great breakwater at Marseille (see DOCKS) has a total length of more than $3\frac{1}{2}$ m. along the shore (fig. 15), and the range of basins enclosed by it is still being extended both N. and S.

Genoa, the greatest port of Italy, was a centre of maritime trade long before the days of Columbus, whose statue overlooks the harbour and who was a native of the city. The old harbour is in a semi-circular bay less than $\frac{3}{4}$ m. in width at its entrance. Around its shores moles and jetties were built from time to time, first in sheltered positions and later in more exposed parts of the bay open to the S.; still later protection moles were thrown out from the two horns of the bay, and the continued expansion of the port has necessitated the construction of an island breakwater—the Galliera mole—(begun in 1877 and still being extended) stretching E. and W. in front of the old harbour at a distance of over $\frac{1}{2}$ m. from the shore (fig. 10), and built in water from 50 to 80 ft. deep. Under its shelter port works have been constructed which are further sheltered by subsidiary moles projected more or less at right angles to the shore.

Trieste.—The Adriatic port of Trieste furnishes another example of lateral expansion. The old port, situated in a small sheltered bay, called the Doganale Basin, is now used mainly for coastwise shipping. Along the coast to the northward and again to the southward across the entrance to the Bay of Muggia, several island breakwaters, having an aggregate length of over 2 m., have been built to shelter the port works which stretch along the coast line.

Naples.—The old harbour of Naples was formed by building small moles or breakwaters in sheltered positions on the western side of the bay. The San Vincenzo breakwater, which is the nucleus of the modern harbour, was begun in 1836. The harbour now reaches across the wide bay from west to east for a distance of over 2 m. and is protected by a series of breakwaters parallel with the shore. Practically the whole of the modern harbour, having a sheltered area of about 1 sq. m., is in deep water and little dredging has been required except alongside some of the quays.

Lateral Breakwaters in Sheltered Positions.—In large land-locked natural harbours and arms of the sea lateral breakwaters parallel with the shore form convenient and effective means of providing shelter from the short wind waves which are generated in them and protection from so much of the ocean swell as may be propagated into the enclosed water area. Behind the shelter of such works, wharves and other port works can be constructed where vessels may berth without risk of damage. In this

manner the naval and commercial harbours in the land-locked Rade at Brest are protected by island breakwaters fronting them. Another example is the harbour of Kobe, situated in a sheltered part of the inland sea of Japan, where wide, solid and well equipped piers, projecting 1,000 to 1,500 ft. from the shore, have been afforded additional protection by the construction of a series of island breakwaters generally parallel with the shore in depths of 35 to 45 ft. These works are still in course of construction (1928).

Many of the ports on the shores of the Great Lakes of North America also furnish examples of lateral breakwater protection as, for instance, Chicago, Buffalo, Port Arthur and Toronto. American lake breakwaters are commonly formed of rubble stone mounds or of timber cribwork filled with stone (*see BREAKWATER*). Breakwaters made in comparatively sheltered positions such as these are naturally of less massive construction than those required in situations exposed to the full force of ocean waves.

Entrances.—Seamen always wish for a wide entrance to a harbour as giving greater facility for safe access; on the other hand, it is important to keep the width as narrow as practicable consistent with easy access, to exclude waves and swell as much as possible and secure tranquillity inside. The result of this conflict is often a compromise. Examples which illustrate the divergence of practice in the dimensions of entrances to artificial harbours have already been mentioned; these differences are mainly due to the equally wide variations in circumstances and exposure, and no generally applicable rule or guiding principle can be formulated, though some authorities maintain that the space between breakwater heads should never be less than the over-all length of the largest vessel expected to enter the port. The advantages which can sometimes be secured by overlapping breakwaters, covering island breakwaters and double entrances, have already been mentioned; on one point, however, there can be no difference of opinion; that is, the increasing length and beam of ocean-going vessels require the provision of entrances of ample width, and the more exposed such entrances are to heavy cross seas and strong cross currents the wider they must be in the interests of the navigator. The difficult nature of the present Durban entrance is an example of this. In tidal harbours, and in those with a large volume of river water discharge, an undue restriction of the width of the entrance may produce a current unsafe for navigation. A strong outgoing stream meeting on-shore waves at an entrance is bound to increase the turbulence and create a dangerous sea at a critical point.

The Natural Harbours of America.—The North American continent is well endowed with naturally sheltered harbours in positions where they serve the necessities of sea-borne trade. In the United States deep water river harbours meet these needs at such ports as New York, at the mouth of the Hudson; Philadelphia, on the Delaware, 88 nautical miles from the sea entrance to Delaware Bay; Portland and Astoria (Oregon), on the Columbia, where, however, dredging has been necessary to deepen parts of the river; and Newport News and other places on the James river, Virginia. Deep land-locked bays or sea inlets provide the harbours of Baltimore, at the head of Chesapeake Bay; Portland (Maine); Boston; and San Francisco; and those at Seattle, Tacoma and other ports in Puget Sound.

Two of the most important Canadian ports, Montreal and Quebec, are situated on the magnificent river St. Lawrence, the former 550 m. from the Gulf of St. Lawrence. Halifax in Nova Scotia is in a large land-locked, deep-water harbour free from ice all the year round. Vancouver harbour, in the sheltered Burrard inlet, is one of the finest on the Pacific coast and is capable of internal development on a large scale. Victoria and Esquimalt harbours are in well protected inlets at the southern end of Vancouver Island; and Prince Rupert, in British Columbia, is a comparatively new deep water port on a narrow and well sheltered arm of the sea.

The finest and most beautifully situated natural harbour in South America is that formed by the land-locked bay of Rio de Janeiro. Buenos Aires, Montevideo and Bahia Blanca are all

estuary ports in sheltered positions, but where dredging operations are necessary to form and maintain deep water channels.

New York Harbour.—The harbour of New York (fig. 4) is one of the most perfect natural havens in the world. It enjoys the advantages of ample water area and depth, shelter, good access, a small tidal range—no more than 5 ft. at springs—and moderate tidal streams. The outer harbour, or Lower Bay, is sheltered by the New Jersey shore and Sandy Hook on one side, and by Long Island on the other. The inner harbour is entered through a channel, called the Narrows, between Staten Island on the W. or New Jersey shore, and Brooklyn on the E. It comprises the deep Upper Bay, the rivers which isolate Manhattan Island, namely, the Hudson, East and Harlem, and numerous bays and creeks of which Newark Bay is the most important. The shore lines, under the jurisdiction of the Port of New York Authority (constituted in 1921), have a combined length of over 480 m., and, if the total berthing space of the piers be added, this figure is increased by about 150 m. Excluding the Lower Bay, the sheltered water area within the jurisdiction of the Port Authority is approximately 150 sq. m. In recent years the development of the trade of the port has led to the building of shipping piers on an extensive scale in positions remote from the old centre of trade in Manhattan Island. In this way Staten Island, Jersey City, Newark and the Long Island shores have become busy centres of maritime trade. More recently still, Jamaica Bay, a sheltered inlet on the S. side of Long Island with access direct from the Lower Bay, has been developed as a new centre of port activity.

The entrance to the Lower Bay is open to the Atlantic, but shelter is afforded by outlying sandbanks. Sandy Hook itself is a long, low spit of sand. Until about 1885 the natural channels through the banks afforded, when suitably marked and buoyed, ample depth and width for all ships using the port. The subsequent deepening of the sea channels, consequent on the growth in the dimensions of transatlantic vessels, has already been referred to. The depths in the sea approaches are now maintained by periodical suction dredging.

The entrance to the harbour through Long Island Sound from the N. and E. is sheltered, but the channel is obstructed by rocky islets and reefs. The navigation of this approach was at one time difficult and even dangerous, but it has been much improved by the removal of many of the rocks by blasting and dredging, notably in the neighbourhood of Hell Gate. The Federal authorities, who are responsible for the improvement and maintenance of channels and all aids to navigation in United States harbours and navigable rivers, are now (1928) engaged in still further improving the channels of the Sound and East river, and a low-water depth of 40 ft. over a width of 1,000 ft. is aimed at. A large proportion of the berths alongside piers and wharves in New York harbour have depths of 30 ft. or more at low-water and in some of them more than 40 ft. depth is available.

San Francisco.—The land-locked bay of San Francisco is 55 m. long and has a water area of about 420 sq.m. with about 200 m. of shore line. Two large rivers, the Sacramento and San Joaquin, flow into it. The entrance to the bay, known as the Golden Gate, is a mile wide and has a greatest depth of 360 ft.; but a bar outside the Golden Gate has a minimum natural depth over it of 33 ft. at high water (springs rise $5\frac{1}{2}$ ft.). The dredging of a channel, 40 ft. deep at low water, through this bar was done in 1924-26. There is also a comparatively narrow channel—the North or Bonita channel—affording an entrance to the harbour, which has a natural depth of 54 feet. The usual American plan of waterfront piers has been followed in the development of the port works at San Francisco.

The Natural Harbours of Australasia.—Some of the most important harbours of Australia and most of the frequented harbours in New Zealand are of natural formation. Pre-eminent is the great land-locked harbour of *Sydney*, one of the finest and most beautiful in the world. No artificial protection is required and no deepening or enlargement of its entrance channel has been necessary to meet the needs of the largest ships. The outer entrance, facing S.E. between two bluffs, known as the north and south Heads, is less than a mile in width at its narrow-

NATURAL AND JETTY HARBOURS OF EUROPE AND AMERICA

1. View of Gibraltar harbour on the bay of Algeciras, showing commercial moles used as a wharf for naval destroyers, and one of the three breakwaters, two of which are connected with the shore on north and south. The third, a detached mole (not shown), is on the west. The port has been valued chiefly as a naval harbour
2. Grand harbour of Valetta, Malta, a bay harbour further protected by two breakwaters. It affords anchorage for the largest war vessels
3. Vancouver, B.C., Canada's chief western port and one of the finest natural harbours on the Pacific coast. Situated on Burrard inlet, an arm of the strait of Georgia, it is the principal westward outlet of Alberta's wheat crop and is served by many steamship lines
4. Army and navy supply base in Hampton Roads, Norfolk, Va., a natural harbour large enough to accommodate 1,000 vessels. The base was established in 1917 and represents an investment of \$30,000,000. It has been leased by the city
5. Aerial view of Dieppe, France, on the English Channel. The entrance from the outer harbour is protected by jetties (background) and leads into the winding Arques river along which are quays for the accommodation of vessels drawing up to 20 feet
6. View of waterfront, San Francisco, showing the Golden Gate (above), the entrance to San Francisco bay, a natural land-locked harbour 55 miles long and well equipped with docking and berthing facilities

est part and has a minimum depth in the channel, nearly $\frac{1}{2}$ m. wide, of 84 feet. The outer part of the harbour is known as Port Jackson, so named by Captain Cook in 1770. Its shores, as well as those of the upper harbour near and above Sydney, are indented by many sheltered coves. The tidal rise is about 5 ft. at springs and shipping is berthed at open piers. The trade of the port is large, Sydney ranking fifth among the empire ports in this respect. Although only 12 m. in a straight line from the Heads to the upper limit of the harbour, the total length of the indented shore line is 188 miles. Of its water area of 23 sq.m. nearly 5 sq.m. have a depth of over 35 ft. at low water. Channels 40 ft. deep have been dredged where necessary to give access to the overseas piers some of which have berths 45 ft. deep at low water.

Melbourne is less fortunately placed than is Sydney, for the city itself is situated on the shallow river Yarra, which discharges into the large land-locked Port Philip Bay. In its natural state the river had a depth of little more than 13 feet. In recent years dredging at the entrance to the bay and in the approach channels to the wharves at Hobson Bay has increased the minimum depth at low water to 34 feet.

Tasmania has several fine natural harbours. *Hobart* is a port on the wide 60 ft. deep river Derwent. There is a perfect approach to the river entrance; no dredging is required; open jetties furnish all the needs of shipping and the capacity for extension is almost unlimited. The Tamar provides in its lower reaches a sheltered deep water harbour for the port of *Launceston*.

New Zealand is rich in good natural harbours. *Port Lyttleton* in the South Island is a sheltered deep water inlet with no bar. Dredging has only been required to deepen and maintain a channel in the approaches to the inner harbour. *Wellington*, at the southern end of the North Island, is a splendid land-locked harbour with over 30 sq.m. of sheltered water, from 6 to 14 fathoms in depth. The entrance is 3,600 ft. in width with a depth of 42 ft. at low water. Open wharves, most of which have a low water depth of over 30 ft., and some as much as 36 ft., project from the shores of the inner or Lambton harbour. *Auckland* harbour, also in the North Island, is an arm of the sea, with an entrance over $\frac{1}{2}$ m. wide, well protected by outlying islands, providing deep water accommodation for the largest vessels.

The Harbours of the East.—The great majority of the important harbours east of Suez are natural havens. Some possess such advantages of depth and shelter that little more than the provision of wharves and other internal port works has been necessary to convert them into first class ports. In others dredging and river training works have been required. Great artificial harbour works in exposed situations such as those at Colombo and Madras are rare in the East; but harbour works on a very large scale have been made in recent years in sheltered waters, particularly in Japan and the Dutch East Indies and at Singapore. A few only of the more important harbours not already referred to can be mentioned here. The harbour of *Bombay* is a well sheltered arm of the sea situated between the island of Bombay and the mainland. *Calcutta* and *Rangoon* are river ports in both of which sand bars and shoals are serious problems (see RIVER ENGINEERING); *Singapore*, one of the greatest trading ports of the east, occupies a sheltered position, protected by outlying islands and shoals, with a deep water anchorage. The new naval base is being made in and on the shores of the channel which separates the island of Singapore from the mainland of Johore (see DOCKS). *Hongkong* island is situated at the mouth of the Canton river. Between it and the mainland at Kowloon is a natural and well sheltered deep-water harbour of great extent. *Kobe* and *Osaka* are large breakwater harbours in sheltered positions in the inland sea of Japan. *Yokohama*, the principal port of Japan, is in the land-locked bay of Tokyo. The port works, including the breakwaters over 12,000 ft. in total length, were partially wrecked by the great earthquake of Sept. 1, 1923, but all the damage has been made good and large additions are being made to the harbour accommodation. *Dairen*, the principal port of Manchuria, has been energetically developed in recent years by the Japanese. It is in a sheltered bay where two island breakwaters and two breakwaters projected from the shore, having a total length of over $2\frac{1}{2}$ m.,

cover a protected water area of 780 acres. At *Manila*, in the Philippines, breakwaters have been made in an almost land-locked bay to protect a harbour of 1,250 acres.

BIBLIOGRAPHY.—See the lists of authorities quoted under BREAKWATERS and DOCKS. The latest series of Sailing Directions published, with annual supplements, by the Hydrographic Department of the Admiralty contains full descriptions of the harbours of the world, and the Admiralty Charts include large scale plans of most of them. (N. G. G.)

HARBURG, a seaport town in the Prussian province of Hanover, on the left bank of the southern arm of the Elbe, 6 m. by rail S. of Hamburg. Pop. (1925) 72,947.

Harburg belonged originally to the bishopric of Bremen, and received municipal rights in 1297. In 1376 it was united to the principality of Lüneburg, along with which it fell in 1705 to Hanover, and in 1806 to Prussia. It is situated at the junction of the main lines of railway from Bremen and Hanover to Hamburg. It possesses a palace, which from 1524 to 1642 was the residence of the Harburg line of the house of Brunswick. The leading industries are the crushing of palm-kernels, for which it is famous, and linseed and the manufacture of india-rubber, gutta-percha, phosphates, nitrate and jute. Machines are manufactured here; beer is brewed, and shipbuilding is carried on.

HARCOURT, a noble French family which took its name from the village of Harcourt (Eure), and traces its origin back to the 11th century. The fief of Harcourt was raised to a county in 1338, and passed in the 15th century, by a marriage, into the house of Lorraine. HENRI DE LORRAINE, COMTE D'HARCOURT (1601-1666), nicknamed Cadet la perle, fought in Italy against Spain in 1639, and captured Turin. He took sides with Condé in the Fronde, but made his submission in 1654.

The most distinguished among the younger branches of the family are those of Montgomery and of Beuvron. To the former belonged Jean d'Harcourt (d. 1452), bishop of Amiens and Tournai, archbishop of Narbonne and patriarch of Antioch; and Guillaume d'Harcourt, count of Tancarville, and viscount of Melun (d. 1487), who was head of the administration of the woods and forests in the royal domain.

From the branch of the marquises of Beuvron sprang Henri d'Harcourt, marshal of France, and ambassador at the Spanish court, who was made duke of Harcourt (1700) and a peer of France (1709); also François Eugène Gabriel, count, and afterwards duke, of Harcourt, who was ambassador first in Spain, and later at Rome, and died in 1865.

The English family of Harcourts trace their descent to Ivo de Harcourt, son of William de Harcourt who acquired English land at the date of the Conquest.

See G. A. de la Rognie, *Histoire généalogique de la maison d'Harcourt* (4 vols., 1662); P. Anselme, *Histoire généalogique de la maison de France*, v. 114, etc.; and Dom le Noir, *Preuves généalogiques et historiques de la maison de Harcourt* (1907); and the HARCOURT PAPERS.

HARCOURT, LEWIS VERNON HARCOURT, 1ST VISCOUNT (1863-1922), British politician, was born in London on Feb. 1, 1863, the elder son of Sir William Harcourt (q.v.). He was educated at Eton and afterwards travelled, becoming well known for his interest in art. In 1899 he married the only daughter of Walter H. Burns, of New York. From 1904 to 1916 he was Liberal M.P. for the Rossendale division of Lancs., and on the formation of Sir Henry Campbell-Bannerman's Government (1905) he became first commissioner of works. In 1910 he became secretary of State for the colonies in the Asquith Cabinet, and on the formation of the Coalition Government in 1915 again became first commissioner of works. In 1917 he was raised to the peerage. He died in London on Feb. 24, 1922, being succeeded in the title by his son, William Edward Harcourt (b. 1908).

HARCOURT, SIMON HARCOURT (c. 1661-1727), 1ST VISCOUNT, lord chancellor of England, only son of Sir Philip Harcourt of Stanton Harcourt, Oxfordshire. On the accession of George I. he was deprived of office and retired to Cokethorpe, where he enjoyed the society of men of letters, Swift, Pope, Prior and other famous writers being among his frequent guests. With Swift, however, he had occasional quarrels, during one of which the great satirist bestowed on him the sobriquet of "Trimming Harcourt." In 1721 Harcourt was created a viscount and returned

to the privy council; and on several occasions during the king's absences from England he was on the council of regency. He died in London on July 23, 1727.

HARCOURT, SIR WILLIAM GEORGE GRANVILLE VENABLES VERNON (1827-1904), English statesman, was the second son of Canon William Vernon, who took the name of Harcourt on the succession of his father Edward, Archbishop of York to the Harcourt estates in 1830. Canon Harcourt is separately noticed. William was born at the Old Residence, York, on Oct. 14, 1827. He was educated privately at Dumford, near Salisbury, and at Preston, where he witnessed the bread riots of 1842. From his tutor at Preston he went up to Trinity college, Cambridge, graduating with a first in classics and a senior optime in the mathematical tripos. He was a member of the famous Society of the Apostles at Cambridge, and among his close friends were Fitzjames Stephen and Julian Fane. He was called to the bar at the Inner Temple in 1854, became a Q.C. in 1866, and was appointed Whewell professor of international law, Cambridge, 1869. He quickly made his mark in London society as a brilliant talker; he wrote for *The Morning Chronicle* and *Saturday Review*, and began in 1862 to write letters to *The Times* over the signature of "Historicus" on questions of international law arising out of the American Civil War. The earlier letters were directed against the recognition of the Southern States as belligerents in the American Civil War and towards defining the duties of neutrality on the part of England. These letters had a profound effect on public opinion. He maintained that the launching of the "Alabama" was an illegal act, and throughout the period was in close touch with Lord John Russell and Lord Clarendon.

He entered parliament as Liberal member for Oxford, and sat from 1868 to 1880, when, upon seeking re-election after acceptance of office, he was defeated by Hall. A seat was, however, found for him at Derby, by the voluntary retirement of Plimsoll, and he continued to represent that constituency until 1895, when, having been defeated at the general election, he found a seat in West Monmouthshire. He was appointed solicitor-general and knighted in 1873; and, although he had not shown himself a very strenuous supporter of Gladstone during that statesman's exclusion from power, he became secretary of state for the home department on the return of the Liberals to office in 1880. His name was connected at that time with the passing of the Ground Game Act (1880), the Arms (Ireland) Act (1881), and the Explosives Act (1883). As home secretary at the time of the dynamite outrages he acted promptly, and the Explosives Act was passed through all its stages in the shortest time on record. He was constantly in conflict with the Irish members in the House of Commons. In 1884 he introduced an abortive bill for unifying the municipal administration of London. He was indeed at that time recognized as one of the ablest and most effective leaders of the Liberal party; and when, after a brief interval in 1885, Gladstone returned to office in 1886, he was made chancellor of the exchequer. The government fell on the Home Rule question in July. In Jan. 1887 Harcourt, who had been a close ally of Joseph Chamberlain before the split in the Liberal party over Home Rule, now made an effort to secure reunion, and the Round Table Conference of Herschell, Harcourt, Morley, Chamberlain and Trevelyan met at his house. It failed disastrously.

Between 1880 and 1892 Harcourt acted as Gladstone's loyal and indefatigable lieutenant in political life. In 1892 he became chancellor of the exchequer for the second time. In 1894 he introduced and carried a memorable budget, which equalized the death duties on real and personal property and put the budget on a basis which enabled it to stand the strain of the South African War. After Gladstone's retirement in 1894 and Lord Rosebery's selection as prime minister, Sir William became the leader of the Liberal party in the House of Commons, but it was never probable that he would work comfortably in the new conditions. His title to be regarded as Gladstone's successor had been too lightly ignored, and from the first it was evident that Lord Rosebery's ideas of Liberalism and of the policy of the Liberal party were not those of Harcourt. Their acute differences were patched up from time to time, but the combination could

not last. At the general election of 1895 the divisions in the party were obvious. The effect of Harcourt's abortive Local Veto Bill on the election was seen in his defeat at Derby, which gave the signal for the Liberal rout. In Dec. 1898 the crisis arrived, and he resigned his leadership of the opposition, alleging as his reason, in letters exchanged between John Morley and himself, the cross-currents of opinion among his old supporters and former colleagues.

Harcourt strongly condemned the government's financial policy and their attitude towards the Transvaal in 1899-1900; and was a constant critic of Chamberlain's policy. At this time he engaged in a violent controversy, conducted in letters to *The Times*, against ritualism in the Church of England. His last great political effort was against Chamberlain's tariff reform proposals. In March 1904, just after he had announced his intention not to seek election again to parliament, he succeeded, by the death of his nephew, to the family estates at Nuneham. But he died suddenly there on Oct. 1 in the same year. He married, first, in 1859, Thérèse Lister (d. 1863), a niece of the 4th Lord Clarendon (q.v.), by whom he had one son, Lewis Vernon Harcourt (q.v.); and secondly, in 1876, Elizabeth, widow of T. Ives and daughter of J. L. Motley, the historian, by whom he had another son, Robert (b. 1878). Lady Harcourt survived until 1928.

Sir William Harcourt was one of the great parliamentary figures of the Gladstonian Liberal period. He was essentially an aristocratic type of the late 19th century Whig, with a remarkable capacity for popular campaign fighting. He had been, and remained, a brilliant journalist in the non-professional sense. He was one of those who really made the *Saturday Review* in its palmy days, and the "Historicus" letters on international law published in *The Times* showed him to be a great international lawyer. In later years he found himself somewhat isolated and disappointed. A tall, fine man, with the grand manner, he was, throughout a long career, a great personality in the life of his time.

See A. G. Gardiner, *The Life of Sir William Harcourt* (2 vol., 1923).

HARCOURT, WILLIAM VERNON (1789-1871), founder of the British Association, was born at Sudbury, Derbyshire, in 1789, a younger son of Edward Vernon [Harcourt], archbishop of York. He served for five years in the British navy and then went up to Christ Church, Oxford, took holy orders, and held a living at Bishopthorpe, Yorkshire. He was one of the founders of the Yorkshire Philosophical Society and its first president. The laws and the plan of proceedings for the British Association for the Advancement of Science were drawn up by him; and Harcourt was elected president in 1839. In 1824 he became canon of York and in 1837 rector of Bolton Percy. His spare time until quite late in life was occupied with scientific experiments. Inheriting the Harcourt estates in Oxfordshire from his brother in 1861, he removed to Nuneham, where he died in April 1871.

HARDANGER FJORD, an inlet on the west coast of Norway, penetrating 70 m. inland apart from the deep fringe of islands off its mouth, the distance from the sea to the head of the fjord being 114 miles. Its extreme depth is about 350 fathoms. With Torö at the entrance, the general direction is north-east from that point. Magnificent mountains, from which pour many waterfalls flank the fjord. The main fjord is divided into parts under different names, and there are many fine branch fjords. The fjord is frequented by tourists, and the principal stations have hotels. The outer fjord is called the Kvintherredsfjord, flanked by the Melderskin (4,680 ft.); then follow Sildefjord and Bonde Sund, separated by Varalds island. Here Mauranger-fjord opens on the east; from Sundal on this inlet the great Folgefond snowfield may be crossed. Bakke and Vikingnaes are stations on Hisfjord, Nordheimsund and Östensö on Ytre Samlen, which throws off a fine narrow branch northward, the Fikensund. There follow Indre Samlen and Utnefjord, with the station of Utne opposite Oxen (4,120 ft.), and its northward branch, Gravenfjord, with the beautiful station of Eide at its head, whence a road runs north-west to Vossevangen. From the Utne terminal branches of the fjord run south and east; the

Sörfjord, steeply walled by the heights of the Folgefond, with the frequented resort of Odde at its head; and the Eidfjord, with its branch Osefjord, terminating beneath a tremendous rampart of mountains, through which the sombre Simedal penetrates. Vik is the principal station on Eidfjord, and Ulvik on a branch of the Ose, with a road to Vossevangen. A small stream entering Sörfjord forms in its upper course the Skjaeggedalsfos, of equal height with the Vörfingfos, and hardly less beautiful.

HARDCORE, a term applied in the building and contracting trades to any clean hard material, other than gravel, suitable for making up roads, pathways, the solid ground floors of buildings, etc. Thus broken bricks or stone, broken up concrete, etc., are all used as hardcore. Material for good work should be clean and entirely free from organic matter. The rise of wages since 1913 has greatly increased the cost of hardcore, as so much labour has to be expended in preparing and transporting it. In 1928 a cubic yard of clean hardcore in London cost six shillings delivered.

HARDEE, WILLIAM JOSEPH (1815-1873), American soldier, was born in Savannah, Ga., on Nov. 10, 1815 and graduated from West Point in 1838. As a subaltern of cavalry he was employed in 1839 on a special mission to Europe to study the cavalry methods in vogue. He was promoted captain in 1844 and served with distinction under Generals Taylor and Scott in the Mexican War. After the war he served as a substantive major of cavalry under Col. Sidney Johnston and Lieut. Col. Robert E. Lee. For some time before 1856 he was engaged in compiling the official manual of infantry drill and tactics which, familiarly called "Hardee's Tactics," afterwards formed the text-book for the infantry arm in both the Federal and the Confederate armies. From 1856 to 1861 he was commandant of West Point, resigning his commission on the secession of his State in the latter year. Entering the Confederate service as a colonel, he was shortly promoted brigadier-general. He distinguished himself greatly by his tactical leadership on the field of Shiloh, and was immediately promoted major-general. As a corps commander he fought under Gen. Bragg at Perryville and Stone river, and for his distinguished services in these battles was promoted lieutenant-general. He served in the latter part of the campaign of 1863 under Bragg and in that of 1864 under J. E. Johnston. When the Civil War came to an end in 1865 he retired to his plantation near Selma, Alabama. He died at Wytheville, Va., on Nov. 6, 1873.

See James Kendall Hosmer, *Outcome of the Civil War*, "American Nation" series, vol. xxi. (1907).

HARDEN, MAXIMILIAN (1861-1927), German journalist, founder and editor of *Die Zukunft*, was born in Berlin on Oct. 20, 1861. He commenced journalism as a keen admirer of Bismarck, and *Die Zukunft*, founded in 1892, made its name by its attacks on the court camarilla, which resulted in a prosecution for libel in 1907. Harden's statements proved to be justified, and Count Kuno von Moltke, who had instituted the prosecution, withdrew from the case and Prince P. Eulenburg fled the country. During the war Harden was a candid critic of the German Government and the German high command. He was just as unsparing in his criticisms of the German revolutionary government and of subsequent administrations. He died on Oct. 30, 1927.

Many of his writings and essays were published under the title of "*Köpfe*" (1910-24, 4 vols.). See *Kautsky and Harden*, by H. Delbrück (1920).

HARDENBERG, KARL AUGUST VON, PRINCE (1750-1822), Prussian statesman, was born at Essenroda, Hanover, on May 31, 1750. He studied at Leipzig and Göttingen, and entered the Hanoverian civil service in 1770. Finding the promotion slow, he spent some time in travel, visiting the South German courts and those of France, Holland and England. On his return he married the countess Reventlow, became privy councillor and a count. He then went to London in the hope of obtaining the post of Hanoverian envoy there, but his wife formed a liaison with the prince of Wales, and he was forced to leave the Hanoverian service. He entered (1782) that of Brunswick, but here again his wife's conduct made his position untenable. They were divorced, and he then married a divorced woman. In 1792 Hardenberg was made administrator of the principalities of Ansbach and Bay-

reuth, which had just fallen to Prussia. He filled this difficult office with great skill, and used it to expand Prussian influence in South Germany. He then received a rising commission as Prussian envoy to the Rhenish courts, and presently succeeded Count Goltz as Prussian plenipotentiary at Basle where he signed (Feb. 28, 1795) the treaty with France.

In 1797, on the accession of Frederick William III., Hardenberg became a member of the Prussian cabinet. He acted as deputy for the foreign minister, Hangwitz, in 1803, and in 1804 succeeded him. The king desired to continue the policy of Prussian neutrality, though he had made an agreement with Russia to take up arms in case of further aggression by Napoleon in north Germany. If there was to be war, Hardenberg would have preferred the French alliance, which was the price Napoleon demanded for the cession of Hanover to Prussia; for the Eastern Powers would scarcely have conceded, of their free will, so great an augmentation of Prussian power. But he still hoped to gain the coveted prize by diplomacy, backed by the veiled threat of an armed neutrality. Napoleon's contemptuous violation of Prussian territory by marching three French corps through Ansbach turned the scale, and the king signed (Nov. 3) with the tsar Alexander the terms of an ultimatum to be laid before the French emperor. The battle of Austerlitz, however, compelled submission. Prussia, indeed, by the treaty signed at Schönbrunn on Dec. 15, 1805, received Hanover, but in return for all her territories in South Germany. One condition of this arrangement was the retirement of Hardenberg, whom Napoleon disliked. He was again foreign minister for a few months after the crisis of 1806 (April-July 1807); but Napoleon's resentment was implacable, and one of the conditions of the terms granted to Prussia by the Treaty of Tilsit was Hardenberg's dismissal.

After the enforced retirement of Stein in 1810 and the interlude of the feeble Altenstein ministry, Hardenberg was again summoned to Berlin, this time as chancellor (June 6, 1810). The campaign of Jena had profoundly affected him. He broke with the old diplomacy, and was inspired with a passionate desire to restore the position of Prussia and crush her oppressors. In his retirement at Riga he had worked out a plan for reconstructing the monarchy on Liberal lines; and though circumstances did not admit of his pursuing an independent foreign policy, he prepared for the struggle with France by carrying out Stein's far-reaching schemes of social and political reorganization. The military system was completely reformed, serfdom was abolished, municipal institutions were fostered, the civil service was thrown open to all classes, and great attention was devoted to the educational needs of every section of the community.

After the Moscow campaign of 1812, Hardenberg, supported by the noble Queen Louise, determined Frederick William to take advantage of Gen. Yorck's loyal disloyalty, and declare against France. He was rightly regarded by German patriots as the statesman who had done most to encourage the spirit of national independence; and immediately after he had signed the first Peace of Paris he was raised to the rank of prince (June 3, 1814) in recognition of the part he had played in the War of Liberation.

Hardenberg now had an assured position in that close corporation of sovereigns and statesmen by whom Europe, during the next few years, was to be governed. He accompanied the allied sovereigns to England, and at the congress of Vienna (1814-15) was the chief plenipotentiary of Prussia. But from this time the zenith of his influence, if not of his fame, was passed. In diplomacy he was no match for Metternich. At Vienna, in spite of the powerful backing of Alexander of Russia, he failed to secure the annexation of the whole of Saxony to Prussia; at Paris, after Waterloo, he failed to carry through his views as to the further dismemberment of France; he had weakly allowed Metternich to forestall him in making terms with the States of the Confederation of the Rhine, which secured to Austria the preponderance in the German federal diet; on the eve of the conference of Carlsbad (1819) he signed a convention with Metternich, by which—to quote the historian Treitschke—"like a penitent sinner, without any formal *quid pro quo*, the monarchy of Frederick the Great yielded to a foreign Power a voice in her internal affairs."

At the congresses of Aix-la-Chapelle, Troppau, Laibach and Verona the voice of Hardenberg was but an echo of that of Metternich.

The cause lay partly in the difficult circumstances of the loosely-knit Prussian monarchy, but partly in Hardenberg's character, which had deteriorated with age. He continued amiable, charming and enlightened as ever; but the excesses which had been pardonable in a young diplomatist were a scandal in an elderly chancellor, and could not but weaken his influence with so pious a *Landesvater* as Frederick William III. Hardenberg clung to office, and when the tide turned strongly against Liberalism he allowed himself to drift with it. He died at Genoa, on Nov. 26, 1822.

Hardenberg* (Leipzig, 1904); F. Hartung, *Hardenberg und die preussische Verwaltung in Ansbach-Bayreuth, 1792-1806* (1906); P. Haake, *Der preussische Verfassungskampf vor hundert Jahren* (1921).

HARDENING. In metallurgy this term has two meanings. First, the hardening of tool-steel throughout in order to fit it for cutting purposes, or to withstand wear when used as a pin, roller, cam, tappet, etc. Second, the surface or case-hardening or carburising of wrought-iron or mild-steel to give it a hard skin suitable for wearing purposes. The first-named treatment is performed by heating the steel to a red or white heat and cooling in water, oil, lead, mercury or in air or a blast according to circumstances. The second by heating the article in a furnace in contact with a case-hardening material which thus penetrates and adds carbon to the surface, and then quenching the steel while red hot. Leather cuttings, hoof parings, horns, bones are packed in a box with the steel and put in the furnace for a period, or a prepared powder is used instead of those substances. The furnaces are much the same as those described under **ANNEALING**. The principal difficulties to contend with in the process are cracking in the case of tool-steels, and warping in case-hardening. See **TEMPERING**.

HARDERWYK, a seaport in the province of Gelderland, Holland, on the shores of the Zuider Zee, 17 m. by rail N.N.E. of Amersfoort. Pop. (1926) 8,701. It is a quaint old town, standing in the midst of a patch of fertile ground. Harderwyk is a depot for recruits for the Dutch colonial army and contains a small fort and barracks. The principal buildings are the town hall, with some ancient furniture, and a large 15th century church with a notable square tower. Agriculture, fishing, and a few domestic industries form the only employment of the inhabitants. As a seaport its trade is now confined exclusively to the Zuider Zee.

HARDHACK (*Spiraea tomentosa*), a North American shrub of the rose family (Rosaceae), called also steeple-bush, native to open grounds from Nova Scotia to Manitoba and southward to Georgia and Kansas. It has an upright, woolly, reddish-brown stem, 2 to 4 ft. high, bearing ovate, pointed, sharply-toothed leaves, which are greyish or yellowish woolly beneath, and a slender, steeple-like flower-spike crowded with tiny deep pink flowers, blooming in late summer. The hardhack, which is sometimes planted for ornament, is especially abundant in eastern

BY COURTESY OF THE WILD FLOWER PRESERVATION SOCIETY

HARDHACK (SPIRAEA TOMENTOSA), A PLANT WHOSE ROOTS ARE SOMETIMES USED AS AN ASTRINGENT AND THE FLOWERS USED AS TONIC

New York and New England, where in many localities it occurs in weedlike profusion, becoming pestiferous in meadows and pastures. (See **SPIRAEA**.)

HARDICANUTE [more correctly **HARTHACNUT**] (c. 1019-1042), son of Canute, king of England, by his wife Emma. On the death of Canute in 1035 the claims of Hardicanute were supported by Emma and her ally, Godwine, earl of the West Saxons, in opposition to those of Harold, Canute's illegitimate son, who was backed by the Mercian earl Leofric and the chief men of the north. Godwine held Wessex for a time on Hardicanute's behalf. Harold's party rapidly increased; and early in 1037 he was definitely elected king. Emma was driven out and took refuge at Bruges. In 1039 Hardicanute joined her, and together they concerted an attack on England. Next year Harold died; and Hardicanute succeeded. His short reign was marked by great oppression and cruelty. He caused the dead body of Harold to be dug up and thrown into a fen; the exaction of a heavy geld for the support of his foreign fleet in Worcestershire, provoked a rising whereupon he burned the city of Worcester to the ground and devastated the surrounding country; in 1041 he permitted Edwulf, earl of Northumbria, to be treacherously murdered after having granted him a safe-conduct. He died on June 8, 1042.

HARDIE, JAMES KEIR (1856-1915), British Labour leader, was born on Aug. 15, 1856, at Legbrannock, Lanarkshire. His early life was one of great hardship; he was employed in the mines from the age of ten. Originally a Liberal in politics, he started, with some friends, in 1887 the *Miner*, afterwards the *Labour Leader*, the first Socialist paper in western Scotland. In the same year he opened the attack, as delegate of the Ayrshire miners at the Trades Union Congress, upon the dominant Liberal members of the parliamentary committee, and continued this struggle, in which his chief allies were John Burns and Tom Mann, up to the decisive defeat of Henry Broadhurst, M.P., his chief opponent, at the Liverpool Congress in 1890. In 1888 he entered politics as an "Independent Labour" candidate for Mid-Lanark, polling only 617 votes; in 1892 he was elected on the same programme for South West Ham, but did not retain the seat in 1895. In 1900 he was elected for Merthyr. He was very largely responsible for the foundation of the Scottish Labour Party in 1888, and the Independent Labour Party (I.L.P.) in 1893. His first great triumph came in 1899, when the Trades Union Congress was induced to authorize the formation of labour representation committees in conjunction with the I.L.P. and other Socialist bodies. Socialist-Labour candidates were, for the first time, run systematically at the ensuing election, and at the 1906 election 29 were returned to parliament. This number was raised to over 40, but the Socialist character of the party was "diluted" by the adhesion *en bloc* of most of the Liberal miners' M.P.'s. Hardie was selected as first chairman, and during the years before the World War had as chief tasks firstly, the persuading of the Liberal trade union representatives to advance further on the Socialist path; secondly, the extension of Socialism by public propaganda outside. In attempting these, he was severely criticized by the Social-Democrats as compromising and muddled in theory; for the right wing of the Labour Party he was too rugged. But there was no doubt of his success, as chief propagandist for the I.L.P., in spreading Socialist tenets in every manufacturing and mining district, until, in 1914, there was scarcely a big industrial town in which there was not a powerful and active I.L.P. or other Socialist branch. For such pioneer work his strong personality, his unquestioned honesty and his lovable character notably fitted him.

In concert with Edouard Vaillant he had made a vain endeavour to bind the Socialist International to calling a general strike in the event of war. The complete failure of this body to act in 1914 was a great disappointment to Hardie; the progress of the war seemed to be undoing his life's work; depression and dejection hastened his death in 1915.

See W. Stewart, *J. Keir Hardie* (1921); D. Lowe, *From Pit to Parliament* (1923).

HARDING, CHESTER (1792-1866), American portrait painter, was born at Conway, Mass., on Sept. 1, 1792. Brought

up in the wilderness of New York State, Harding, as a lad of splendid physique, standing over 6ft. 3in., marched as a drummer with the militia to the St. Lawrence in 1813. He became subsequently chairmaker, peddler, innkeeper, and house-painter, painting signs in Pittsburgh, Pa., and eventually going on the road, self-taught, as an itinerant portrait painter. He made enough money to take him to the schools at the Philadelphia Academy of Design, and he soon became proficient enough to gain a competency, so that later he went to England and set up a studio in London. There he met with great success, painting royalty and the nobility, and, despite the lack of education in boyhood, and social experience, he became a favourite in all circles. Returning to the United States, he settled in Boston and painted portraits of many of the prominent men and women of his time. He died on April 1, 1866.

HARDING, WARREN GAMALIEL (1865-1923), 29th President of the United States, was born at Corsica (then Blooming Grove), Morrow county, Ohio, on Nov. 2, 1865, son of George Tyron Harding, a farmer and country doctor, and Phebe Elizabeth Dickerson. He studied in the common schools, and from 14 to 17 at the Ohio Central college at Iberia. He taught in a country school for a year, read law for a short time, worked in a newspaper office and in 1884 became editor and proprietor of the *Marion Star*. On July 8, 1891, he married Florence Kling. Having attracted the notice of Senator Joseph B. Foraker, he was encouraged to enter State politics, and was early recognized as an effective speaker. He served two terms in the Ohio senate (1900-04), and during the second was influential in securing Senator Foraker's re-election to the U.S. Senate. From 1904 to 1906 he was lieutenant-governor of Ohio, but in 1910, when nominated for governor by the Republicans, was defeated by a plurality of 100,000. In the campaign of 1912 his paper supported President Taft. In 1914 he defeated Foraker in the Republican primaries as candidate for the U.S. Senate, and was elected with a majority of 100,000 for the term of 1915-21; his friendship with Foraker remained unchanged.

In 1916 Mr. Harding was delegate-at-large from Ohio to the Republican National Convention, of which he was chosen permanent chairman. In the Senate he was regarded as a "safe" man, who could be relied upon to support orthodox Republican policies. In 1915 he urged "preparedness" for naval defence. In 1916 he voted against the confirmation of Louis D. Brandeis as associate justice of the U.S. Supreme Court. In 1917 he gave his support to the declaration of war against Germany, and also to all the war measures, including the Selective Draft and Espionage bills. He favoured the death penalty for spies, but after the war advocated amnesty for political prisoners. He opposed the suggested Federal control of food and fuel. He favoured the Prohibition amendment and voted for the Volstead Act over the President's veto. He favoured the anti-strike clause of the Cummins Railway bill, and voted for return of the lines to their owners within a year after the end of the war. He was for exempting American shipping from Panama Canal tolls and also supported woman suffrage. He was opposed to the Covenant of the League of Nations, holding that "either the Covenant involves a surrender of national sovereignty and submits our future destiny to the League, or it is an empty thing, big in name, and will ultimately disappoint all of humanity that hinges its hopes upon it." He voted for the Lodge resolution of ratification of the Versailles Treaty, with reservations, and against the Underwood resolution of unconditional ratification. He maintained that Americans should show chief concern for America, and opposed all tendencies toward internationalism. He supported the Knox resolution declaring that war with Germany was ended.

At the Republican National Convention in 1920 Mr. Harding was not at first among the prominent candidates for president. On the first ballot he received 65½ votes (493 being necessary for choice), 39 of these being from his own State. On the eighth ballot he received 133½ votes, on the ninth 374½ votes, and on the tenth he secured the nomination with 692½ votes, the result being due largely to the support of certain influential U.S. Senators, delegates to the convention, who hoped that as president he

would be amenable to the Senate. He did not "stump" the country, but conducted his campaign from the "front porch" of his own home. Mr. Harding based his campaign chiefly upon criticism of the Wilson administration, denouncing especially the excessive power that, as he maintained, had been exercised by the executive as a result of war centralization; he demanded as speedy as possible a return to normal conditions, political and industrial.

While opposing the Covenant of the League of Nations, Mr. Harding gave to many of his supporters the impression that he desired an "association of nations," which, without the characteristics of a super-State (such as he believed the League to be), might safeguard peace. But he retained the political support of many who were opposed, like Senators Borah and Johnson, to any sort of international association. In the November elections he won an overwhelming victory over James M. Cox, the Democratic nominee, also from Ohio; he carried, generally by immense majorities, all the northern States and all but one of the States on the border between North and South, and he cut down materially the Democratic majorities in the South. The electoral vote was 404 for Harding against 127 for Cox. The popular vote was 16,138,000 for Harding against 9,142,000 for Cox. In Ohio the popular vote was 1,182,000 for Harding against 780,000 for Cox. The sweeping character of his victory was due less to his own personal strength than to the national reaction against the Democratic Party and the popular feeling against President Wilson. Mr. Harding resigned from the U.S. Senate in Dec. 1920, and was inaugurated on March 4, 1921, the sixth President to come from Ohio.

President Harding's cabinet, like most cabinets, was a *mélange* of men of native ability and political or industrial experience and Party leaders who claimed office as a reward for services rendered the new President. The outstanding names were those of Charles E. Hughes and Herbert C. Hoover, who became Secretary of State and of Commerce respectively. The distinguished career of the former and the widespread confidence in his ability and political integrity had marked him for the most important position in the Cabinet; and there had been a general demand that the new administration should utilize the organizing ability displayed by Hoover in many fields. The choice of Andrew W. Mellon, a wealthy banker and ironmaster of Pittsburgh, as Secretary of the Treasury, was welcomed by men of business. Political and personal debts were paid by the choice of Albert B. Fall as Secretary of the Interior, Harry M. Daugherty as Attorney General and Will H. Hays as Postmaster General. The conduct of administrative and political affairs by these and others less prominent in the new administration, later brought intense criticism upon the President and the Republican Party.

Mr. Harding's inaugural address, and his first message to Congress, delivered in person on April 12, voiced his desire to return to "normalcy," as he expressed it. Retrenchment in expenditure formed a major item in his programme, together with a prompt and thorough revision of taxation. He advocated the adoption of a national budget system, and the Congress having passed a Budget bill similar to that vetoed by Wilson in 1920, he approved it on June 10, 1921; it provided for a Budget Bureau in the Treasury Department and the appointment of a director of the budget, the first being Charles G. Dawes, formerly general purchasing agent of the American Expeditionary Force. President Harding's first budget was presented on Dec. 5, 1921. The President was insistent upon the need of repealing the excess profits taxes and reducing transportation taxes and income surtaxes. The need of financial retrenchment led to his opposing the proposal that war veterans should receive a cash bonus. In this matter, as in others, he proved his ability at this early stage to resist political pressure. As regards the tariff he advocated, as a temporary stop-gap, the passing of the emergency tariff, which had been vetoed by President Wilson, but which with slight alteration was approved by Harding on May 27, 1921. He urged the need of adopting a permanent tariff policy, and on Dec. 5, 1921, suggested a "flexible tariff" which might provide for the adjustment of rates to meet unusual and changing conditions. Such

adjustments might be made, in his opinion, by the executive on the advice of the Tariff Commission.

As regards domestic legislation, the President, in general, assumed the rôle of moderator. He disclaimed any desire to enlarge the powers and responsibilities of the executive, which, he declared, were already too large; and he aimed at close co-operation with Congress. Foreign policy was largely determined by Hughes, financial by Mellon, and the problem of unemployment was thrown upon Hoover. The President, however, frequently played an active rôle in the conferences necessary to secure general agreement, as on Aug. 9, 1921, when an accord was reached between the Treasury and the Representatives on the taxation plan.

The foreign policy of the administration at first seemed likely to emphasize independence of action, in contradistinction to that of President Wilson; the threatened war between Panama and Costa Rica was prevented by a sharp note from Secretary Hughes; the claims of the Japanese to a mandate over Yap were stoutly denied; the administration refused to follow Great Britain in resuming trade relations with Soviet Russia. President Harding made plain in his first message that the United States would not enter the League of Nations. In rejecting the League Covenant, he said, "we make no surrender of our hope and aim for an association to promote peace, in which we would most heartily join." The President advocated a declaration of peace with Germany by resolution, and the immediate negotiation of a treaty. This policy was adopted by Congress, which agreed upon a joint peace resolution, signed by him on July 2. On Aug. 25, 1921, a treaty with Germany was signed, embodying the President's plan of including most of the stipulations of the Versailles Treaty, but repudiating adherence by the United States to any clause referring to the League of Nations. This treaty and similar pacts with Austria and Hungary were ratified by the Senate on Oct. 18, 1921.

The most important step taken by President Harding during the first year of his administration was the calling of an international conference on the limitation of armaments. On May 25, 1921, the Senate adopted an amendment of Senator Borah to the Navy bill, authorizing and inviting the President to call such a conference. Mr. Harding's preliminary invitations to the principal naval Powers (Great Britain, Japan, France and Italy) were sent July 10, and formal invitations Aug. 11. He indicated his belief that the question was closely connected with the problems of the Pacific and Far East, and invitations were also sent accordingly to China and to the smaller European Powers with Far-Eastern interests—Holland, Belgium and Portugal. The invitations were accepted, and the conference assembled at Washington on Nov. 12. The President made it clear that he regarded the conference merely as a step in securing international understanding and good-will; he advocated the convening of succeeding conferences as a possible means of securing an international association for the promotion of peace, and he approved the principle of substituting an understanding between the United States, Great Britain, France and Japan regarding Far-Eastern problems for the existing Anglo-Japanese Treaty. See WASHINGTON CONFERENCE.

The Washington Conference was the highwater mark of the Harding Administration. Thereafter he faced the development of blocs in the Republican Party which destroyed its solidarity, and the growth of criticism which was manifested in the elections of 1922, as a result of which the Republican majority in the House was reduced. The administrative incompetency of office-holders in Washington was widely heralded and there was more than a suspicion of corrupt dealing on the part of cabinet members and their political followers, who were known to be close to the President. Government investigations later verified such suspicions and revealed an extent of political immorality in Washington such as had no parallel in recent times. Harding himself enjoyed personal popularity; his nature was kindly and genial, and there was general confidence in his honesty and devotion to his duties; but he was regarded as easy-going in his relations with friends and disinclined to scrutinize their activities critically. Resentment was voiced against the Republican national organization controlled by the Old Guard; there was outspoken criticism of the

new tariff; keen discontent among the farmers led to the election to the Senate of Shipstead and Magnus Johnson. Again the threat of a Third Party became imminent.

In the summer of 1923 Mr. Harding set forth on a tour across the United States and to Alaska, designed to reassure the farmers and reawaken enthusiasm for the administration. The President, already tired, became ill on the trip back from Alaska and was stricken with pneumonia in San Francisco. On Aug. 2, 1923, he died suddenly. (C. SEY.)

HARDINGE, HENRY HARDINGE, VISCOUNT (1785–1856), British field marshal and governor-general of India, was born at Wrotham, Kent, on March 30, 1785. He entered the army in 1799 as an ensign in the Queen's Rangers, a corps then stationed in Upper Canada. He served right through the peninsular campaigns, and in the Waterloo campaign was British commissioner at Prussian headquarters. He was wounded at Ligny on June 16, 1815, where he lost his left hand by a shot, and thus was not present at Waterloo, fought two days later. He received a pension of £300, a K.C.B., and Wellington presented him with a sword that had belonged to Napoleon. In 1820 and 1826 Sir Henry Hardinge was returned to parliament as member for Durham; and in 1828 became secretary for war in Wellington's ministry, a post which he also filled in Peel's cabinet in 1841–44. In 1830 and 1834–35 he was chief secretary for Ireland. He succeeded Lord Ellenborough as governor-general of India. During his term of office (1844–48) the first Sikh War broke out; and Hardinge, waiving his right to the supreme command, magnanimously offered to serve as second in command under Sir Hugh Gough; but disagreeing with the latter's plan of campaign at Ferozeshah, he temporarily reasserted his authority as governor-general (see SIKH WARS). After the Sobraon campaign he was created a viscount, and received a pension of £3,000 for three lives. Hardinge's term of office in India was marked by many social and educational reforms. In 1852 he succeeded Wellington as commander-in-chief of the British army. In the Crimean War he endeavoured to direct the army on Wellington's principles—a system not altogether suited to the changed mode of warfare. In 1855 he was promoted field marshal. Hardinge resigned in July 1856, and died on Sept. 24, of the same year at South Park near Tunbridge Wells.

See C. Hardinge, *Viscount Hardinge* (Rulers of India series, 1891); and R. S. Rait, *Life and Campaigns of Viscount Gough* (1903).

HARDINGE OF PENSHURST, CHARLES HARDINGE, 1ST BARON (1858–), British diplomat, was born in London on June 20, 1858, second son of the 2nd Viscount Hardinge. He was educated at Harrow and Trinity College, Cambridge, and in 1880 entered the diplomatic service. He became secretary of legation at Teherân in 1896, and in 1898 went to St. Petersburg (Leningrad) as secretary of embassy. In 1903 he returned to England and became assistant under-secretary for foreign affairs, and later (1906–10) permanent under-secretary. In the latter capacity he accompanied Edward VII. on his foreign visits. He was created K.C.M.G. in 1904, G.C.M.G. in 1905 and K.G. in 1916. From 1904 to 1906 he was ambassador to Russia, and in 1910 was appointed Viceroy of India and raised to the peerage. Lord Hardinge returned to England in 1916 and was reappointed to the post of permanent under-secretary of foreign affairs. In Nov. 1920 he succeeded Lord Derby as ambassador in Paris, retiring in 1922.

HARD MONEY, a term used in the United States of America, but not in Great Britain, to designate metallic money and to distinguish it from paper money. It came into existence in the days of the Greenback Party. (See GREENBACKS.)

HARDNESS TESTING. Hardness in the widest sense is that property of any material which causes it to resist deformation by external forces. It is necessary to know the exact degree of hardness of a metal so that, by using a metal corresponding to a given analysis and subjecting it to heat treatment, it can be brought to its maximum strength. It is therefore desirable to have some exact method of determining hardness so that a standard quality of the product may be obtained. Tests are made to determine the uniformity of the grade of the metal; the tensile

and other strengths in relation to its hardness; the frictional and antifrictional qualities in accordance with its hardness; the elimination and checking of flaws in defective materials; the exactness of temper (*see TEMPERING*) in heat treatment; and the homogeneity of the metal. Fig. 1 shows the various methods used in the determination of the hardness of a material.

The scratch test as proposed by Mohs is one of the oldest methods of testing, and is used by geologists to determine to some degree the hardness of rock and other similar substances. The scratch test, perfected by Martens, depends upon the width of scratch produced by dragging across the surface of the material a diamond point under a definite load. The average width of the scratches, measured by microscope, is checked against a chart with calibrated numbers on it. A hard surface gives a narrow scratch, and a soft one a wide scratch.

About 1900, J. A. Brinnell brought out a method of testing which consists in measuring the indentation produced by forcing in the material a hardened steel ball of definite size, under a steady pressure. The Brinnell machine operates on the hydraulic principle and is provided with a dead-weight roller valve for maintaining the desired load on the plunger, at one end of which is located the ball that is used to make the indentation. This consists of a spherical piston, accurately fitted to a cylinder which is connected to a pressure chamber. This piston carries a cross-bar and weight. The maximum pressure is limited by the weights, and when the desired pressure is reached the piston rises in the cylinder. The load remains constant as long as the piston chamber is full of oil, and the oil is put under a pressure by a hand-operated plunger pump. The pressure varies from 50 to 3,000 kg., according to the part or kind of material being tested. The area of the impression is obtained with a measuring microscope, with a magnification of ten, which permits the reading in

tube by a vacuum, and then, being released, falls on the part to be tested. The height of the rebound is noted on the scale as well as the point where the hammer stops momentarily before it falls downward again, and the degree of hardness is thus determined.

Fig. 2 shows the Rockwell hardness-testing machine. This method of testing is of the latest type, and has gained considerable headway in nearly all lines of industries in the United States and other parts of the world. The results obtained by this method are quick and accurate; little experience is required by the operator. It is well adapted to mass production methods of manufacturing, on account of the quickness to which a test can be made, averaging about 5 sec. per test. The principle consists of impressing a hardened steel or diamond point into the surface to be tested, and measuring the depth of the penetration—the resistance of the metal indicating the degree of hardness. The test points and weights used are of such small size that no damage is done to the piece tested. The

BY COURTESY OF WILSON MAEULEN CO.

FIG. 2.—THE ROCKWELL MACHINE USED IN TESTING THE HARDNESS OF METALS

averaging depth of the penetration in the softest of steel is only about 0.008 inch. Because of the accuracy required, a positive mechanical means of depth measurement is used. This consists of the dial, shown in fig. 2, which is calibrated with this mechanism so that a reading can be made quickly.

HARDOI, a town and district of British India, in the Lucknow division of the United Provinces. The town is 63 m. N.E. of Lucknow by rail. Pop. (1921) 14,412. It has a wood-carving industry, saltpetre works, and an export trade in grain.

The DISTRICT OF HARDOI has an area of 2,332 sq.m. It is a level district watered by the Ganges, Ramganga, Deoha or Garra, Sukheta, Sai, Baita and Gumti—the three rivers first named being navigable by country boats. Towards the Ganges the land is uneven, and often rises in hillocks of sand cultivated at the base, and their slopes covered with lofty *munj* grass. Several large *jhils* or swamps are scattered throughout the district, the largest being that of Sāndi, which is 3 m. long by from 1 to 2 m. broad. Large tracts of forest jungle still exist. Leopards, black buck, spotted deer, and *nilgai* are common; the mallard, teal, grey duck, common goose, and all kinds of waterfowl abound. In 1921 the population of the district was 1,084,410. Hardoi contains a larger urban population than any other district in Oudh.

The first authentic records of Hardoi are connected with the Mohammedan colonization. Bawan was occupied by Sayyid Salar Masaud in 1028, but permanent occupation did not begin till 1217. Between Bilgram and Sandi was fought the great battle between Humayun and Sher Shah, in which the former was utterly defeated. Hardoi, along with the rest of Oudh, became British territory under Lord Dalhousie's proclamation of Feb. 1856.

HARDOUIN, JEAN (1646–1729), French classical scholar, was born at Quimper in Brittany. About the age of 16 he was admitted into the order of the Jesuits. He eventually became librarian of the Collège Louis le Grand in Paris, and died there on Sept. 3, 1729. He edited Pliny's *Natural History* for the Delphin series and in the course of this work became interested in numismatics. His work in this department was marred, like the rest of his work, by a passion for originality. It includes *Nummi antiqui populorum et urbium illustrati* (1684), and *Antirrheticus de nummis antiquis* (1689). He also supervised the *Conciliorum collectio regia maxima* (1715), holding the view that all councils prior to the council of Trent were fictitious. Among his many paradoxical theories, the most remarkable is that contained in *Prolegomena ad censuram veterum scriptorum*, to the effect that the vast

hundredths of millimetres; this measurement is checked against a chart which gives the degree of hardness.

The *scleroscope*, invented by A. F. Shore, is another important method of testing hardness. This instrument operates on the rebound principle, and has a diamond pointed cylindrical hammer (weighing less than an ounce) encased in a vertical glass tube which guides the hammer. This tube has a scale giving the different degrees of hardness, with the numbers starting from the bottom upward, as the high numbers up the scale represent the harder metals. The hammer is brought to the top of the

majority of the existing classical works are spurious productions of the works of the 13th century.

HARDT, THE, a mountainous district of Bavaria, forming the northern end of the Vosges range. It is, in the main, an undulating plateau of sandstone, of a mean elevation of 1,300 ft., and the highest point is the Donnersberg (2,254 ft.). The eastern slope, towards the Rhine, is diversified by deep well-wooded valleys, such as the Lauter and the Queich, and by conical hills surmounted by ruins of feudal castles and monasteries, e.g., the Madenburg near Eschbach, the Trifels (long the dungeon of Richard I. of England), and the Maxburg near Neustadt. Three-fifths of the area is occupied by forests, principally oak, beech and fir. The lower eastern slope is highly cultivated and produces excellent wine.

HARDWAR, an ancient town of British India, and Hindu place of pilgrimage, in the Saharanpur district of the United Provinces, on the right bank of the Ganges, at the point where the Ganges debouches from the foot-hills of the Himalayas into the plains. Pop. (1921), 30,764. The position is of great natural beauty, and the river at this point has special sanctity. The town is of great antiquity, and has borne many names. It was originally known as Kapila from the sage Kapila. Hsüan Tsang, the Chinese Buddhist pilgrim, in the 7th century visited a city which he calls Mo-yu-lo, the remains of which still exist at Mayapur, a little to the south of the modern town. Among the ruins are a fort and three temples, decorated with broken stone sculptures. The goal of the vast numbers of Hindus who visit Hardwar is the Hari-kacharan, or bathing ghat, with the adjoining temple of Gangadwara. The charan or foot-mark of Vishnu, imprinted on a stone let into the upper wall of the ghat, forms an object of special reverence; and water from the pool below is carried off all over India, for use on solemn occasions. A great assemblage of people takes place annually, at the beginning of the Hindu solar year, (April-May), when the sun enters Aries. Since 1892 many sanitary improvements have been made for the benefit of the annual concourse of pilgrims. In early days riots and also outbreaks of cholera were of common occurrence. It is at Hardwar that the main Ganges canal takes off from the river; and the headworks are an engineering feat of much interest.

HARDWARE, a term applied to a large variety of metal goods, especially domestic ironmongery and appliances, hand tools, small metal manufactures such as stoves used in building, garden appliances, etc. Next to food and clothing, hardware is perhaps the chief necessity of humanity. In Britain alone a research into retail sales based upon the actual stock replacements of hardware retailers over a period of six months (*Hardware Trade Journal*, vol. cxvii., 1924) showed on a conservative basis a turnover of £120,000,000, or approximately £3 per head of the population, per annum. The per head consumption, however, is considerably greater, for there are in addition millions annually spent on builder's hardware for new buildings of all kinds, and by gas and electricity supply undertakings on lighting, cooking and heating appliances which do not come into the retail accounts.

Inventive genius is constantly widening the scope of the trade, and the tendency is specially marked in the multiplicity of modern labour-saving appliances for the house. It is impossible to indicate accurately the relative importance of various sections of the trade, but the furnishing side covers a large part of it.

Birmingham, "the city of a thousand trades," is known the world over as the great hardware metropolis, practically every class being made there. One leading branch is the manufacture of "hollow-ware"—cast-iron, galvanized, enamelled and aluminium products for domestic and other uses. Cast-iron pots are still largely sold both for home and export, but the trade has suffered from the competition of enamelled goods and the newer aluminium ware. A notable development in the enamelled branch has been the introduction of colours. Aluminium hollow-ware—which may be cast, deep-drawn under heavy pressure, or spun from the flat disk of metal—enjoys increasing popularity, on account of its cleanliness, lightness and purity. Cast aluminium ware is the most

expensive kind and is largely used for ships and hotel kitchens. The manufacture of hearth suites, curbs and companion sets, and fire screens, is another great industry. New metals and finishes to eliminate labour of cleaning have been adopted; the goods are made in copper, Grecian bronze, satin brass, oxidized silver and stainless steel. Birmingham is a centre for electro-plated ware, and also for brassfoundry.

Cutlery and electro-plate trades have been centred in Sheffield for generations. Machine processes and mass production methods are increasingly applied in the cutlery industry. Hand-forged crucible steel blades are still made, but machine processes have been brought to a fine pitch of perfection, and the tradition for quality products is well maintained. The manufacture of stainless steel (q.v.) by Mr. Harry Brearley in the Brown-Firth Research Laboratory prior to the World War, was one of the most far-reaching developments in the history of steel; not only has it largely revolutionized the cutlery trade, but it has proved of great value in the engineering and allied industries. Just as progress has been recorded in regard to steel for cutlery purposes, so also there have been important developments in subsidiary materials. Handles of xylonite are now used for most table knives. Great improvements have been made in precision grinding, and especially in measures for safeguarding the health of the workers engaged in grinding operations. Changes have been made in the razor section. Safety razor blades are produced—millions per week—in the United States, Great Britain and Germany.

In plated goods, an innovation is the use of chromium. Chromium plating applied to base metal is used not only for flat-ware like spoons and forks, but for hollow-ware, plumbers' fittings, bathroom taps, plugs, and wastes, and other goods for domestic and industrial uses where the "stainless" requisite is desirable.

Builders' Hardware.—This is produced in many centres. Light castings—stoves, ranges, grates, baths and rainwater pipes—are staple manufactures of Falkirk, where the industry was established in 1759. Stoves and ranges for solid fuel have long been made; now, in addition, the industry is meeting new needs for cooking and heating appliances using gas or electricity. Here again stainless steel is being more extensively utilized. Mechanical methods are rapidly superseding old laborious hand practice. Machine moulding, for instance, is extending. Large outputs of light castings are made from foundries at Rotherham, Leeds, Warrington, Birmingham, in the Black Country and at Luton. Wire manufacture is the chief industry of Warrington; and wire netting works are situated there and also in Manchester, Norwich, and London.

Willenhall and Wolverhampton are the most important centres for locks and latches. Corrugated iron is largely produced in London, Ellesmere Port, Glasgow and South Wales, and in the West Riding of Yorkshire; metal casements are made in Essex; plumbers' brassfoundry and fittings in various centres, but largely in Birmingham, and screws and nails also in the Midlands. There are still a few hand nail makers in the Black Country, but their output is negligible compared with the production of modern factories. Birmingham's output of screws is over a million per week, and there is a big output also at Leeds. Sheffield manufacturers produce saws and wood-working tools, engineering tools and appliances, tools for road making and agricultural work and garden requisites. In the Midlands there are works devoted to the manufacture of edge tools, and particularly tools for use on plantations in tropical countries. Agricultural implement making is carried on in Scotland, in the West Riding of Yorkshire and in the Eastern counties; motor lawn mowers and electrically driven lawn mowing machines are among the latest developments in this branch of the industry. The domestic washing machine trade is carried on in Lancashire, Yorkshire and in Glasgow; and Keighley (Yorks) is the leading centre of production for laundry machinery. Carpet sweepers and domestic mops are largely produced in Lancashire; and brushes of all kinds at Oldham, St. Albans, London and Wymondham.

An outstanding feature of the hardware trade is its tremendous scope and its varied range of patterns. The best minds in the trade are now directed towards simplification by the elimination

of many patterns and sizes. Great progress has already been made in the United States with standardization, through the Division of Simplified Practice, Department of Commerce, Washington, and something has been done in Great Britain, largely as a result of the work of the British Engineering Standards Association. A conference on the subject was held at the Board of Trade in 1928.

THE UNITED STATES

At the beginning of the 19th century this term meant chiefly mechanics' tools and builders' hardware, but in 1928, in the United States, it included all small metal articles used in the construction of houses or for household purposes, tools of mechanics' trades, furnishing goods for kitchen and dining room service, tin plate, sheet iron, nails, screws, fence wire, etc. It is not uncommon for a large hardware house to have in its catalogues nearly 100,000 kinds and sizes of articles. In the early American colonial period supplies were brought from the mother countries of Europe. As the colonies assumed a definite shape, the village blacksmith established the foundation of American hardware manufacture, by making bars for doors, tools and implements for agriculture. But greater development was both necessary and desirable due to the isolation of the colonies and the finding of coal and minerals in great abundance. Small home manufacture grew up to supply local demands, but the greatest part of the manufactured goods were imported. Immigrants brought their own tools, the patterns of which were at once copied and improved. Village blacksmiths in Connecticut and thereabouts began to make farm implements and simple hand tools about 1850, and in 1860 American manufacturers began to pull trade away from competitors by virtue of higher quality goods. Labour-saving machinery was introduced later and foreign-made articles could not compete.

The hardware-manufacturing industry had its beginnings in New England. The business gradually spread into the middle Atlantic States, especially New York and Pennsylvania. In the latter part of the 19th century New York became the undisputed centre of the trade. Here were located the majority of the great importing houses, and here also were founded and flourished the jobbers who distributed to the retail trade. With the growth of the country new advance manufacturing centres were created, and New York was no longer the pre-eminent trade centre. Since 1875 the States of Ohio, Indiana, Illinois and Michigan have been large producers. More recently Wisconsin, Iowa and Minnesota also have been important manufacturers of hardware.

Builders', cabinet and furniture hardware, which includes trimmings such as knobs, handles, pulls, hinges and lock supports and such kindred items, and cabinet, desk, draw, sewing machine, phonograph and piano locks, are manufactured in Pennsylvania, Wisconsin, Illinois and in several of the New England States, particularly Connecticut. Shelf hardware and padlocks are also made in the New England States, as well as in Pennsylvania and New York. Piano hardware is another group of products made largely in New England. Tools for working in wood, such as hammers, chisels, saws, planes, augers, in fact a complete line of carpenters' and cabinet-makers' tools, are produced in the New England States, Pennsylvania, New York and Ohio, and these States are renowned for the excellent hand and power saws, which they produce. Most screws, including machine screws and wood screws, are produced in Rhode Island and Connecticut.

(W. H. SIE.)

HARDWICKE, PHILIP YORKE, 1ST EARL OF (1690–1764), English lord chancellor, was born at Dover on Dec. 1, 1690, the son of Philip Yorke, an attorney. Called to the bar at the Middle Temple in 1715, he afterwards joined Lincoln's Inn, of which he was bencher and treasurer in 1724. He sat in parliament for Lewes 1719 and Seaford 1722–34; was solicitor general (1720), attorney general (1723), lord chief justice and baron Hardwicke (1733), lord chancellor (1737). For many years from 1743 onwards Lord Chancellor Hardwicke held the controlling power in the Government. During the king's absences on the Continent he presided over the council of regency, and he had to cope with the Jacobite rising of 1745. After Culloden he presided

at the trial of the Scottish Jacobite peers. He carried out the great reform of 1746, which swept away the private heritable jurisdictions of the Scottish landed gentry; among his other great legal services was the reform of the English marriage laws.

Hardwicke, who was created earl in 1754, retired with Newcastle in Nov. 1756, but he helped to secure the coalition between Newcastle and Pitt in 1757. He died in London on March 6, 1764.

Hardwicke was not a statesman of the first rank, but he was one of the greatest judges who ever sat on the English bench. Lord Campbell pronounces him "the most consummate judge who ever sat in the court of chancery, being distinguished not only for his rapid and satisfactory decision of the causes which came before him, but for the profound and enlightened principles which he laid down, and for perfecting English equity into a systematic science." He held the office of lord chancellor longer than any of his predecessors, with a single exception; and Campbell asserts that as an equity judge Hardwicke's fame "has not been exceeded by that of any man in ancient or modern times. His decisions have been, and ever will continue to be, appealed to as fixing the limits and establishing the principles of the great juridical system called Equity, which now not only in this country and in our colonies, but over the whole extent of the United States of America, regulates property and personal rights more than the ancient common law." Hardwicke had prepared himself for this great and enduring service to English jurisprudence by study of the historical foundations of the chancellor's equitable jurisdiction, combined with profound insight into legal principle, and a thorough knowledge of the Roman civil law, the principles of which he scientifically incorporated into his administration of English equity in the absence of precedents bearing on the causes submitted to his judgment.

Nor was the creation of modern English equity Lord Hardwicke's only service to the administration of justice. Born within two years of the death of Judge Jeffreys, his influence was powerful in obliterating the evil traditions of the judicial bench under the Stuart monarchy and in establishing the modern conception of the duties and demeanour of English judges.

BIBLIOGRAPHY.—The contemporary authorities for the life of Lord Chancellor Hardwicke are voluminous, being contained in the memoirs of the period and in numerous collections of correspondence in the British Museum. See, especially, the *Hardwicke Papers*; the *Stowe MSS.*; *Hist. MSS. Commission* (Reports 2, 3, 4, 6, 8, 9, 11); Horace Walpole, *Letters* (ed. by P. Cunningham, 9 vols., London, 1857–59); *Letters to Sir H. Mann* (ed. by Lord Dover, 4 vols., London, 1843–44). See also Lord Campbell, *Lives of the Lord Chancellors*, vol. v. (8 vols., London, 1845); Edward Foss, *The Judges of England*, vols. vii. and viii. (9 vols. London, 1848–64); George Harris, *Life of Lord Chancellor Hardwicke*; with *Selections from his Correspondence, Diaries, Speeches and Judgments* (3 vols., London, 1847).

HARDWICKE STAKES: see HORSE RACING.

HARDWOODS. A term applied in commercial usage to woods that are close in grain, heavy, and therefore hard and strong. It is not a scientific classification. The chief hardwoods in common use are oak, chestnut, elm, beech, ash, mahogany, walnut, maple, teak, sycamore, rosewood and greenheart. These are all the products of broad-leaved or foliage trees. Many beautiful and valuable hardwoods are known to the botanist, and indeed to the timber trade, which are not generally used by furniture manufacturers. Among these may be mentioned Indian laurel, Australian blackwood, silky oak and Australian walnut. (See TIMBER.)

HARDY, ALEXANDRE (1569?–1631), French dramatist, was born in Paris. He was one of the most fertile of all dramatic authors, and himself claimed to have written some 600 plays, of which, however, only 34 are preserved. He seems to have been connected all his life with a troupe of actors headed by a clever comedian named Valleran-Lecomte, whom he provided with plays. Hardy toured the provinces with this company, which gave some representations in Paris in 1599 at the Hôtel de Bourgogne.

Valleran-Lecomte occupied the same theatre in 1600–03, and again in 1607, apparently for some years. In consequence of disputes with the Confrérie de la Passion, who owned the privilege of the theatre, they played elsewhere in Paris and in the provinces

for some years; but in 1628, when they had long borne the title of "royal," they were definitely established at the Hôtel de Bourgogne. Hardy's numerous dedications never seem to have brought him riches or patrons. His most powerful friend was Isaac de Laffemas (d. 1657), one of Richelieu's most unscrupulous agents, and he was on friendly terms with the poet Théophile, who addressed him in some verses placed at the head of his *Théâtre* (1632), and Tristan l'Hermite had a similar admiration for him. Hardy's plays were written for the stage, not to be read; and it was in the interest of the company that they should not be printed and thus fall into the common stock. But in 1623 he published *Les Chastes et loyales amours de Théagène et Cariclée*, a tragi-comedy in eight "days" or dramatic poems; and in 1624 he began a collected edition of his works, *Le Théâtre d'Alexandre Hardy, parisien*, of which five volumes (1624-28) were published, one at Rouen and the rest in Paris. These comprise eleven tragedies: *Didon se sacrifiant*, *Scédase ou l'hospitalité violée*, *Panthée*, *Méléagre*, *La Mort d'Achille*, *Coriolan*, *Marianne*, a trilogy on the history of Alexander, *Alcméon, ou la vengeance féminine*; five mythological pieces; 13 tragi-comedies, among them *Gésippe*, drawn from Boccaccio; *Phraarte*, taken from Giraldu's *Cent excellentes nouvelles* (1584); *Cornélie*, *La Force du sang*, *Félimène*, *La Belle Égyptienne*, taken from Spanish subjects; and five pastorals, of which the best is *Alphée, ou la justice d'amour*.

Hardy's importance in the history of the French theatre can hardly be overestimated. Up to the end of the 16th century mediaeval farce and spectacle kept their hold on the stage in Paris. The French classical tragedy of Étienne Jodelle and his followers had been written for the learned, and in 1628 when Hardy's work was nearly over and Rotrou was on the threshold of his career, very few literary dramas by any other author are known to have been publicly represented. Hardy educated the popular taste, and made possible the dramatic activity of the 17th century. He had abundant practical experience of the stage, and modified tragedy accordingly, suppressing chorus and monologue, and providing the action and variety which was denied to the literary drama. He was the father in France of tragi-comedy, but cannot fairly be called a disciple of the romantic school of England and Spain. It is impossible to know how much later dramatists were indebted to him in detail, since only a fraction of his work is preserved, but their general obligation is amply established.

See *Le Théâtre d'Alexandre Hardy*, edited by E. Stengel (Marburg and Paris, 1883-84, 5 vols.); E. Lombard, "Étude sur Alexandre Hardy," in *Zeitschr. für neufranz. Spr. u. Lit.* (Oppeln and Leipzig, vols. i. and ii., 1880-81); K. Nagel, *A. Hardy's Einfluss auf Pierre Corneille* (Marburg, 1884); and especially E. Rigal, *Alexandre Hardy* . . . (1889) and *Le Théâtre français avant la période classique* (1901).

HARDY, THOMAS (1840-1928), English novelist and poet, was born in Dorsetshire on June 2, 1840. His family was one of the branches of the Dorset Hardys, formerly of influence in and near the valley of the Frome, claiming descent from JOHN LE HARDY of Jersey (son of Clement Le Hardy, lieutenant-governor of that island in 1488), who settled in the west of England. His maternal ancestors were the Swetman, Childs or Child, and kindred families, who before and after 1635 were small landed proprietors in Melbury Osmond, Dorset, and adjoining parishes.

Early Life.—He was educated at local schools, 1848-54, and afterwards privately, and in 1856 was articled to John Hicks, an ecclesiastical architect of Dorchester. In 1859 he began writing verse and essays, but in 1861 was compelled to apply himself more strictly to architecture, sketching and measuring many old Dorset churches with a view to their restoration. In 1862 he went to London (which he had first visited at the age of nine) and became assistant to the late Sir Arthur Blomfield, R.A. In 1863 he won the medal of the Royal Institute of British Architects for an essay on *Coloured Brick and Terra-cotta Architecture*, and in the same year won the prize of the Architectural Association for design. In March 1865 his first short story was published in *Chambers's Journal*, and during the next two or three years he wrote a good deal of verse, being somewhat uncertain whether to take to architecture or to literature as a profession.

In 1867 he left London for Weymouth, and during that and the following year wrote a "purpose" story, which in 1869 was accepted by Messrs. Chapman and Hall. The manuscript had been read by George Meredith, who asked the writer to call on him, and advised him not to print it, but to try another, with more plot. The manuscript was withdrawn and rewritten, but never published.

Novels.—In 1870 Hardy took Meredith's advice too literally, and constructed a novel that was all plot, which was published in 1871 under the title *Desperate Remedies*. In 1872 appeared *Under the Greenwood Tree*, a "rural painting of the Dutch school," in which Hardy had already "found himself," and which he has never surpassed in happy and delicate perfection of art. *A Pair of Blue Eyes*, in which tragedy and irony come into his work together, was published in 1873. In 1874 Hardy married Emma Lavinia, daughter of the late T. Attersoll Gifford of Plymouth. His first popular success was made by *Far from the Madding Crowd* (1874), which, on its appearance anonymously in the *Cornhill Magazine*, was attributed by many to George Eliot. Then came *The Hand of Ethelberta* (1876), described, not inaptly, as "a comedy in chapters"; *The Return of the Native* (1878), the most sombre and, in some ways, the most powerful and characteristic of Hardy's novels; *The Trumpet-Major* (1880); *A Laodicean* (1881); *Two on a Tower* (1882), a long excursion in constructive irony; *The Mayor of Casterbridge* (1886); *The Woodlanders* (1887); *Wessex Tales* (1888); *A Group of Noble Dames* (1891); *Tess of the D'Urbervilles* (1891), Hardy's most famous novel; *Life's Little Ironies* (1894); *Jude the Obscure* (1895), his most thoughtful and least popular book; *The Well-Beloved*, a reprint, with some revision, of a story originally published in the *Illustrated London News* in 1892 (1897).

In all this work Hardy is concerned with one thing, under two aspects; not civilization, nor manners, but the principle of life itself, invisibly realized in humanity as sex, seen visibly in the world as what we call nature. He is a fatalist, perhaps rather a determinist, and he studies the workings of fate or law (ruling through inexorable moods or humours), in the chief vivifying and disturbing influence in life, women. His view of women is more French than English; it is subtle, a little cruel, not as tolerant as it seems, thoroughly a man's point of view, and not, as with Meredith, man's and woman's at once. He sees all that is irresponsible for good and evil in a woman's character, all that is untrustworthy in her brain and will, all that is alluring in her variability. He is her apologist, but always with a reserve of private judgment. No one has created more attractive women of a certain class, women whom a man would have been more likely to love or to regret loving. In his earlier books he is somewhat careful over the reputation of his heroines; gradually he allows them more liberty, with a franker treatment of instinct and its consequences. *Jude the Obscure* is, perhaps, the most unbiased consideration in English fiction of the more complicated questions of sex. There is almost no passion in his work, neither the author nor his characters ever seeming able to pass beyond the state of curiosity, the most intellectually interesting of limitations, under the influence of any emotion. In his feeling for nature, curiosity sometimes seems to broaden into a more intimate communion. The heath, the village with its peasants, the change of every hour among the fields and on the roads of that English countryside which he has made his own—the Dorsetshire and Wiltshire "Wessex"—mean more to him, in a sense, than even the spectacle of man and woman in their blind and painful and absorbing struggle for existence. His knowledge of women confirms him in a suspension of judgment; his knowledge of nature brings him nearer to the unchanging and consoling element in the world. All the entertainment which he gets out of life comes to him from his contemplation of the peasant, as himself a rooted part of the earth, translating the dumbness of the fields into humour. His peasants have been compared with Shakespeare's; he has the Shakespearean sense of their placid vegetation by the side of hurrying animal life, to which they act the part of chorus, with an unconscious wisdom in their close, narrow and undistracted view of things.

The order of merit was conferred upon Hardy in July 1910, and in his later years he received increasing recognition, not only as a great novelist but also as a poet, until by common consent he was admitted the undisputed sovereign of English letters. His great epic-drama *The Dynasts* (1904-08), a chronicle play of England's struggle against Napoleon, with an accompaniment of philosophic comment chanted by a chorus of "phantom intelligences," was in part produced at the Kingsway theatre, London, in the early months of the World War, and again at Oxford in 1920. Several volumes of lyrical poetry followed (*Selected Poems* in 1916; *Collected Poems* in 1919—but now incomplete). His first wife died in 1912, and in 1914 he married Florence Emily, daughter of Edward Dugdale, herself a writer of children's books and articles in periodicals. Both on his 70th and his 80th birthday he received, in his house near Dorchester (from which, latterly, he seldom moved), tributes of respect and admiration representing the English-speaking world.

Three Periods.—Thomas Hardy's career naturally divides itself into three periods. The first of these contains his work as a novelist, and ends with *Jude the Obscure* in 1896 (*The Well-beloved*, published in book form in 1897, appeared serially in 1892). Throughout the series of the novels these gradually become more and more insistent—first as an element of irony, but later as the tragic essence of the narrative—a characteristic metaphysic, in which the strivings and passions of individuals are in fruitless conflict with the inexorable process of the world. *Jude the Obscure*, despite its splendid qualities, made it clear that such a theme could not be adequately developed in the form of the novel; a form was required in which the author could speak out his own convictions without violating aesthetic propriety.

Accordingly, the second period consists of *The Dynasts*, the three parts of which were issued separately in 1904, 1906, 1908; no doubt the greatest single achievement of his career. It may be said that this great poem was written in order to give full utterance, in artistic form, to his peculiar metaphysic. That, however, was not its originating intention, which was simply to celebrate as a chronicle play England's part in the Napoleonic wars. But as the conception grew and deepened, and as to the human action the superhuman comment of "phantom intelligences" was added, the poem became the summation of Hardy's vision of life; and thereby achieved a unity which, in its intrinsic grandeur, and in its perfect command over immense wealth of matter, can only be compared with such monuments of man's destiny as *Faust* and *Paradise Lost*. In diction, however, *The Dynasts* will not bear any such comparison.

The third period may be said to begin with *Time's Laughing-stocks* in 1909, and is wholly devoted to lyrical poetry. It is not often that an artist's life can be divided so definitely into separate stages, each stage characterized by the use of a different form; and, next to its length and plenty, and consistently noble idiosyncrasy, this tripartite division is, perhaps, the most remarkable feature of Hardy's career as a whole. The lyrical period, however, does not give us an entirely new development of his genius. While he was writing novels, he had occasionally experimented with poetry, and some of the results were published in *Wessex Poems* (1898) and *Poems of the Past and the Present* (1901), between *Jude the Obscure* and *The Dynasts*. The volumes published since *The Dynasts* also contain a good many more of these earlier poems. But from 1909 onwards Hardy wrote nothing but lyrical poetry, and this may therefore be truly called his lyrical period. (*A Changed Man*, in 1913, merely rescued from the periodicals of former years several stray pieces of minor fiction.) It represents a new concentration of his power, but certainly no diminution of it. Devotion to lyrical expression has produced a mastery almost as signal in its kind as his command of the art of fiction; and his 70th year saw him beginning, with *Time's Laughing-stocks*, the series of volumes—*Satires of Circumstance* (1914), *Moments of Vision* (1917), *Late Lyrics and Earlier* (1922), *Human Shows, Far Phantasies* (1925), and the posthumous volume *Winter Words* (1928), which has shown him to be the most original, the most poignant, and also the

most copious of contemporary lyrical poets.

Poetry.—The originality of the technique in these volumes does not by any means consist in a mere breach with the accepted conventions, but rather in its highly individual—to some, perhaps, rather disconcerting—compound of the conventional and the unconventional. Most of these lyrics maintain an exact and even rigid formality of stanza, in which a scheme of rhymes is imposed, as it seems, arbitrarily and at all costs. The effect is sometimes justified by its music; but more often by the compact force its pressure gives to language almost conversational in its idiom and choice of words. Yet the diction which defies poetic tradition and seems to despise the magic of elaborated verbal suggestion, is oddly blended with stiff literary phrases and even with words one might expect only lexicographers to think of. The truth seems to be that, in lyrical technique, Hardy had no prejudices either for or against the conventions. He is simply concerned with the matter which intense feeling and profound understanding have enabled him to imagine in a way peculiarly his own, and to express this faithfully he has forged a technique peculiarly his own, out of whatever the language of literature or of speech could offer him. Readers who are willing to allow him this liberty can hardly fail to be impressed, as perhaps nowhere else in recent poetry, by the subtlety, depth and variety of his versions of the experiences common to humanity; the commonplace becomes in his hands something rich and strange. Naturally, the habits of thought and outlook on the world, which we find progressively insistent in the series of the Wessex novels, and which inspire the turbulent matter and monumental structure of *The Dynasts*, are very evident also in the lyrics; which, indeed, are often in the nature of marginal comments on themes previously used.

But something like the quintessence of his tragic power may be found in such ballads as "A Trampwoman's Tragedy," or such keen discrimination of pathos as "Near Lanivet," and something too like the quintessence of his irony to be altogether comfortable in *Satires of Circumstance* or "Ah, are you Digging on My Grave?" Nor is the rustic humour of his beloved Dorset villagers wanting, nor the vivid delight in nature, in the extraordinary range of his lyrical art. It is, in fact, the same Hardy in the lyrics as in the novels and *The Dynasts*; but a Hardy who, if his lyrics were all we had of him, would surely, by virtue of them alone, hold a secure, indeed a unique, position in modern English literature.

Thomas Hardy died on Jan. 12, 1928, and while, in deference to the feeling of the whole English-speaking world, his ashes were buried in Westminster Abbey, in consideration of his deep affection for his native Wessex and the peculiar inspiration it gave him, his heart was buried in his parish churchyard.

The position which he occupied in English literature on account both of his literary merits and of his great age, was an unique one. Known generally as "the last of the great Victorians," his death seemed to snap the last link connecting with the famous nineteenth century litterateurs.

See Annie Macdonell, *Thomas Hardy* (1894); Lionel P. Johnson, *The Art of Thomas Hardy* (1894); F. A. Hedgecock, *Thomas Hardy penseur et artiste* (Paris, 1911); L. Abercrombie, *Thomas Hardy, a critical study* (1912). In 1928 appeared his *Memoirs*, written in the third person, which will always be indispensable for the proper understanding of his genius. See also S. C. Chew, *Thomas Hardy* (1928), and A. E. Newton, *Thomas Hardy, Novelist or Poet?* (1929). (L. A.)

HARDY, SIR THOMAS DUFFUS (1804-1878), English antiquary, belonged to a family famous in the annals of the British navy. Born at Port Royal in Jamaica on May 22, 1804, he crossed over to England and in 1819 entered the Record Office in the Tower of London. Trained under Henry Petrie (1768-1842) he gained a sound knowledge of palaeography, and soon began to edit selections of the public records. From 1861 until his death on June 15, 1878, he was deputy-keeper of the Record Office, which just before his appointment had been transferred to its new London headquarters in Chancery Lane. Hardy, who was knighted in 1873, had much to do with the appointment of the Historical Manuscripts Commission in 1869. Sir T. Hardy edited the Close Rolls, *Rotuli litterarum clausurarum*, 1204-1227 (2 vols.,

1833-44), and the Patent Rolls. *Rotuli litterarum patentium, 1201-1216* (1835) with introduction, "A Description of the Patent Rolls, to which is added an Itinerary of King John." He also edited the *Rotuli de oblatiis et finibus* (1835), which deal also with the time of King John. He edited many other important series of documents. His best known work is the invaluable *Descriptive Catalogue of Materials relating to the History of Great Britain and Ireland* (3 vols., 1862-71).

HARDY, SIR THOMAS MASTERMAN, Bart. (1769-1839). British vice-admiral, of the Portisham (Dorsetshire) family of Hardy. was born on April 5, 1769, and in 1781 began his career as a sailor. He became lieutenant in 1793, and in 1796, being then attached to the "Minerve" frigate, attracted the attention of Nelson by his gallant conduct. He continued to serve with distinction, and in 1798 was promoted to be captain of the "Vanguard," Nelson's flagship. In the "St. George" he did valuable work before the battle of Copenhagen in 1801. He was Nelson's flag-captain on the "Victory" at the battle of Trafalgar in 1805, witnessed Nelson's will, and was in close attendance on him at his death. Hardy was created a baronet in 1806. He was then employed on the North American station, and later (1819), was made commodore and commander-in-chief on the South American station. In 1825 he became rear-admiral, and in December 1826 escorted the expeditionary force to Lisbon. In 1830 he was made first sea lord of the admiralty, being created G.C.B. in 1831. In 1834 he was appointed governor of Greenwich hospital, where he died on Sept. 20, 1839.

See Broadley and Bartelot, *The Three Dorset Captains at Trafalgar* (1906), and Nelson's Hardy, *his Life, Letters and Friends* (1909).

HARDYNG or HARDING, JOHN (1378-1465), English chronicler, was born in the north, and as a boy entered the service of Sir Henry Percy (Hotspur), with whom he was present at the battle of Shrewsbury (1403). He then passed into the service of Sir Robert Umfraville, under whom he was constable of Warkworth Castle, and served in the campaign of Agincourt in 1415 and in the sea-fight before Harfleur in 1416. In 1424 he was on a diplomatic mission at Rome, where at the instance of Cardinal Beaufort he consulted the chronicle of Trogus Pompeius. Umfraville, who died in 1436, had made Hardyng constable at Kyme in Lincolnshire, where he probably lived till his death about 1465. Under Henry V. Hardyng was employed to investigate the feudal relations of Scotland to the English Crown. For this purpose he visited Scotland, at much expense and hardship. For his services he says that Henry V. promised him the manor of Geddington in Northamptonshire. Many years after, in 1439, he had a grant of £10 a year for similar services. In 1457 there is a record of the delivery of documents relating to Scotland by Hardyng to the earl of Shrewsbury, and his reward by a further pension of £20. It is clear that Hardyng was well acquainted with Scotland, and James I. of Scotland is said to have offered him a bribe to surrender his papers. But the documents, which are still preserved in the Record Office, have been shown to be forgeries and were probably manufactured by Hardyng himself. Hardyng spent many years on the composition of a rhyming chronicle of England. The original edition ending in 1436 had a Lancastrian bias and was dedicated to Henry VI. Afterwards he prepared a version for Richard, duke of York (d. 1460), and the chronicle in its final form was presented to Edward IV. after his marriage to Elizabeth Woodville in 1464.

The version of 1436 is preserved in Lansdowne ms. 204, and the best of the later versions in Harley ms. 661, both in the British Museum. Richard Grafton printed two editions in Jan. 1543, which differ much from one another and from the now extant manuscripts. Sir Henry Ellis published the longer version of Grafton with some additions from the Harley ms. in 1812.

See Ellis's preface to Hardyng's *Chronicle*, and Sir F. Palgrave's *Documents illustrating the History of Scotland* (for an account of Hardyng's forgeries).

HARE, AUGUSTUS JOHN CUTHBERT (1834-1903), English writer and traveller. He wrote guide-books to the principal countries and towns of Europe. He also wrote *Memorials of a Quiet Life* (1872), and a long autobiography, *The Story of My*

Life (6 vols., 1896-1900).

HARE, SIR JOHN (1844-1921), English actor and manager, was born in Yorkshire on May 16, 1844, and was educated at Giggleswick school, Yorkshire. He made his first appearance on the stage at Liverpool in 1864, coming to London in 1865, and acting for ten years with the Bancrofts. He made his mark in T. W. Robertson's comedies, and in 1875 became manager of the Court theatre. In association with Mr. and Mrs. Kendal at the St. James's theatre from 1879 to 1888 he established his popularity in London, in important "character" and "men of the world" parts, the joint management of Hare and Kendal making this theatre one of the chief centres of the dramatic world for a decade. In 1889 he became lessee and manager of the Garrick theatre, where (though he was often out of the cast) he produced several important plays, such as Pinero's *The Profligate* and *The Notorious Mrs. Ebbsmith*, and had a remarkable personal success in the chief part in Sydney Grundy's *A Pair of Spectacles*. In 1897 he took the Globe theatre, where his acting in Pinero's *Gay Lord Quex* was another personal triumph. He became almost as well known in the United States as in England, his last tour in America being in 1900 and 1901. He was knighted in 1907. His last appearances were in 1917 in *A Pair of Spectacles* (July and Sept.). He died in London on Dec. 28, 1921.

HARE, JULIUS CHARLES (1795-1855), English theological writer, was born at Valdagno, near Vicenza, Italy, on Sept. 13, 1795. He was educated at Charterhouse and Trinity college, Cambridge, where he became fellow in 1818. He was ordained in 1826, and in 1832 succeeded his uncle in the rich family living of Hurstmonceaux, Sussex, where he accumulated a library of some 12,000 volumes, especially rich in German literature. In 1840 Hare, who belonged to the "Broad Church" party, was appointed archdeacon of Lewes. He married in 1844 Esther, a sister of his friend Frederick Maurice. In 1851 he was collated to a prebend in Chichester; and in 1853 he became one of Queen Victoria's chaplains. He died on Jan. 23, 1855.

In 1827 *Guesses at Truth by Two Brothers* written in collaboration with his brother Augustus William Hare was published. His numerous other works include a *Vindication of Luther* (1854), and an edition, with a life, of the *Remains of John Sterling* (1848), who had formerly been his curate. Carlyle's *Life of John Sterling* was written through dissatisfaction with Hare's "Life." A. J. C. Hare's *Memorials of a Quiet Life* (1872) contains accounts of the Hare family.

HARE, the name of the well-known English rodent now designated *Lepus europaeus*. The name includes all the numerous allied species which do not come under the designation of rabbits. (See RABBIT.) In parts of Europe, where the ordinary species does not occur, its place is taken by the closely allied blue, or mountain hare, the true *L. timidus* of Linnaeus, and the type of the genus *Lepus* and the family *Leporidae*. (See RODENTIA.) The blue hare is a smaller animal with a more rounded and relatively smaller head, and the ears, hind-legs and tail shorter. In southern Sweden it is permanently of a light fulvous grey, with black tips to the ears, but in more northerly districts the fur—except the black ear-tips—changes to white in winter, and still farther north the animal appears to be white at all seasons. In Ireland there is an allied species, *L. hibernicus*, distinguished by its more russet colouring, and the partial or complete absence of the white winter coat. The range of the common hare extends from England across southern and central Europe to the Caucasus; while that of the blue or mountain species reaches from Scotland and Scandinavia through northern Europe and Asia to Japan and Kamchatka, and thence to Alaska.

The hare takes readily to the water, where it swims well; an instance having been recorded in which one was observed crossing an arm of the sea about a mile in width. Hares are remarkably prolific, pairing when scarcely a year old, and the female bringing forth several broods in the year. The young are born covered with hair and with the eyes open, and after being suckled for a month are able to look after themselves. In Europe this species has seldom bred in confinement, although an instance has recently been recorded. It will interbreed with the blue hare.

Hares (and rabbits) have a cosmopolitan distribution with the exception of Madagascar and Australasia; and are now divided into numerous genera mentioned in the article RODENTIA. The most important of these groups is the typical genus which contains over 80 different species distributed over Europe, Asia, N. America and Africa. Some hares look more like rabbits than hares and are frequently referred to as such; for instance, the American "cotton-tails" (*Sylvilagus*) and "jack-rabbits" (*Macrotolagus*). The more northern N. American hares, like the Polar hare (*L. arcticus*) and the Greenland hare (*L. groenlandicus*), turn white in winter. Southern forms, like the wood-hare, gray rabbit, or cotton-tail (*S. floridanus*), do not change colour. The Brazilian hare (*S. brasiliensis*) is nearly allied to the wood-hare.

HAREBELL, known also as the blue-bell of Scotland, and witches' thimbles, a well-known perennial wild flower, *Campanula rotundifolia*, a member of the bell-flower family (*Campanulaceae*). The harebell has a very slender slightly creeping root-stock, and a wiry, erect stem. The leaves at the base of the stem, to which the specific name *rotundifolia* refers, have long stalks, and are roundish or heart-shaped with a wavy or toothed margin; the lower stem leaves are ovate or lance-shaped, and the upper ones linear, almost stalkless, acute and entire. The flowers are slightly drooping, arranged in a panicle, or in small specimens single, having a smooth calyx, with narrow pointed erect segments, the corolla bell-shaped, with slightly recurved segments, and the capsule nodding, and opening by pores at the base. The plant is found on heaths and pastures throughout Great Britain and flowers in late summer and in autumn; it is widely spread in the north temperate zone. In North America it occurs in meadows and on moist rocks from Labrador to Alaska and southward to Pennsylvania, Illinois and Nebraska and in the Rocky Mountains to Arizona and in the Cascades and the Sierra Nevada to northern California. (See CAMPANULA.)

HAREM (hah'rēm or hah'rēm) (Arabic *ḥarīm*, "forbidden"), a name applied to that part of a house in Muslim countries set apart for the women; it is also used collectively for the women themselves. Zenana (strictly *zanāna*, from Persian *zan*, woman) is the term used in India; andarūn (Persian "inner part") (sc. of a house) in Persia. The Indian harem system is also known as *pardah* or *pardah*, literally the name of the curtain used to separate the women's quarters from the rest of the house. In Muhammadan countries theoretically a woman must veil her face to all men except her father, her brother and her husband; but among certain Muslim communities (e.g., in parts of Albania) women of the poorer classes may appear in public unveiled.

Turkish Harems.—The Turkish Republic in 1926 made polygamy illegal; but even before that date it was not common, for, though the Qur'an permits four wives, the man of average possessions was perforce content with one, and a small number of female servants.

The imperial seraglio was a unique institution, an elaborately organized community with a complete system of officers, disciplinary and administrative, and strict distinctions of status. The real ruler of this society was the sultan's mother, the *Sultana Validé*, who exercised her authority through a female superintendent, the *Kyahya Khatun*. She had also a large retinue of subordinate officials (*Kalfas*) ranging downwards from the *Has-*

nadar ousta ("Lady of the Treasury") to the "Mistress of the Sherbets" and the "Chief Coffee Server." Each of these officials had under her a number of pupil-slaves (*alaiks*), whom she trained to succeed her if need be, and from whom the service was recruited. After the sultana validé ranked the mother of the heir-apparent, called the *Bash Kadın Efendi* ("Her excellency the Chief Lady"). Next came the ladies who had borne the younger children of the sultan, the *Hanum Efendis*, and after them the so-called Odalisks or Odalisques (a perversion of *odalik*, from *odah*, chamber). Every odalisk who had been promoted to the royal couch received a *daira*, consisting of an allowance of money, a suite of apartments, and a retinue, in proportion to her status. Since all the harem women were slaves, the sultans, with practically no exceptions, never entered into legal marriage contracts.

The security of the harem was in the hands of a body of eunuchs both black and white. The chief of the white eunuchs, the *kapu aghasi* ("master of the gates") had part control over the ecclesiastical possessions, and even the vizier could not enter the royal apartments without his permission. The chief of the black eunuchs, usually called the *kislar aghasi* ("master of the maidens"), though his true title was *darus se'adet aga* ("chief of the abode of felicity"), was an official of high importance. His secretary kept count of the revenues of the mosques built by the sultans. The number of eunuchs was always a large one. The sultana validé and the bash kadın effendi each had fifty at their service, and others were assigned to the favourite odalisks.

The ordinary middle-class household was naturally on a very different scale. The *selamlık* (or men's quarters) was on the ground floor with a separate entrance, and there the master of the house received his male guests; the rest of the ground floor was occupied by the kitchen and perhaps the stables. The *haremlık* (or women's quarters) was generally (in towns at least) on the upper floor fronting on and slightly overhanging the street; it had a separate entrance, courtyard and garden. Communication with the *haremlık* was effected by a locked door, of which the Effendi kept the key and also by a sort of revolving cupboard (*dutap*) for the conveyance of meals.

The presence of a second wife was the exception, and was generally attributable to the absence of children by the first wife. The expense of marrying a free woman led many Turks to prefer a slave woman who was much more likely to be an amenable partner. If a slave woman bore a child she was often set free and then the marriage ceremony was gone through.

The harem ladies frequently drove into the country and visited the shops and public baths. Their seclusion had very considerable compensations, and from the moment when a woman, free or slave, entered into any kind of wifely relation with a man, she had a legally enforceable right against him both for her own and for her children's maintenance. She had absolute control over her personal property whether in money, slaves or goods; and, if divorce was far easier in Islam than in Christendom, still the marriage settlement had to be of such amount as would provide suitable maintenance in that event.

On the other hand, of course, the system was open to the gravest abuse, and in countries like Persia, Morocco and India, the life of Muslim women and slaves was often far different from that of middle class women of European Turkey, where law was strict and culture advanced.

Since the middle of the 19th century familiarity with European customs and the direct influence of European administrators has brought about a certain change in the attitude of Orientals to the harem system, and in educated circles those who have more than one wife are spoken ill of; but Turkey is the only Muhammadan country that has abolished polygamy altogether.

In India various attempts have been made by societies, missionary and other, as well as by private individuals, to improve the lot of the zenana women. Zenana schools and hospitals have been founded, and a few women have been trained as doctors and lawyers for the special purposes of protecting the women against their own ignorance and inertia. Similarly, trained medical women are introduced into zenanas by the Lady Dufferin Associa-

HAREBELL (*CAMPANULA ROTUNDIFOLIA*), SHOWING DEVELOPMENT
A, flower bud with corolla, 2 sepals, and 3 stamens removed to show that stamens ripen before pistil matures
B, Later stage, when stamens are withering and trifid stigma is open and ready to receive pollen

tion for medical aid to Indian women. In India, as in Turkey, the introduction of Western dress and education has begun to create new ideas and ambitions, and not a few Eastern women have induced English women to enter the harems as companions, nurses and governesses.

Among the principal societies which have been formed to better the condition of Indian and Chinese women in general with special reference to the zenana system are the Church of England Zenana Missionary Society and the Zenana Bible and Medical Mission. Much information as to the medical, industrial and educational work done by these societies will be found in their annual reports and other publications.

HARFLEUR, a port of France in the department of Seine-Inférieure, about 6 m. E. of Havre by rail. Pop. (1926) 4,534. It lies in the valley of the Lézarde, near the estuary of the Seine. Harfleur is identified with *Caracotinum*, the principal port of the ancient Calates. In the middle ages, when its name, Herosfloth, Harofluet or Hareflot, still indicated its Norman derivation, it was the principal seaport of north-western France. In 1415 it was captured by Henry V. of England, but in 1435 the people of the district of Caux rose against the English, and got rid of the foreign yoke. Between 1445 and 1449 the English were again in possession; but the town was recovered for the French by Dunois. In the 16th century the port began to dwindle in importance owing to the silting up of the Seine estuary and the rise of Havre. In 1562 the Huguenots put Harfleur to pillage, and its registers and charters were destroyed; but its privileges were restored by Charles IX. in 1568, and it was not till 1710 that it was subjected to the "taille." The port was improved on the opening of the Tancarville canal (1887) connecting it with the port of Havre and with the Seine. Vessels drawing 18 ft. can moor alongside the quays of the new port, which is on a branch of the canal, has some trade in coal, timber and grain, and carries on fishing. The church of St. Martin with its lofty stone steeple forms a landmark for the pilots of the river. It dates from the 15th and 16th centuries. Of the old castle there are only insignificant ruins. The industries include distilling, metal founding, flour milling and the manufacture of oil and grease.

HARGREAVES, JAMES (1834–1915), English industrial chemist, was born at Hoarstones, Pendle Forest. He received his early instruction in chemistry from his father who was a chemist and druggist. Hargreaves's ability in devising new chemical processes may be gathered from the fact that he obtained more than 200 British and foreign patents to protect his inventions. In 1856 he tried to devise a method of recovering sulphur from alkali waste; this brought him in contact with Gossage, the soap manufacturer. Hargreaves was employed by Gossage until 1865; during this period he discovered a method of bleaching the brown soap in common use, he invented blue mottled soap, and devised a method of recovering chromates from the fats and oils used in soap manufacture. Hargreaves also worked out a process for the recovery of phosphates from the slag of blast furnaces, he obtained chlorine and peroxide of iron as by-products of this process. Soon after he left Gossage he tried to use sodium nitrate in place of air in the Bessemer steel process. A factory was erected but the method proved too costly and had to be abandoned. In 1873 he erected works for the manufacture of hydrochloric acid by the action of the gases from pyrites burners on common salt; these works were eventually acquired by the United Alkali company. In conjunction with one of his employees,

Bird, he invented the Hargreaves-Bird process for the manufacture of soda by the electrolytic decomposition of salt. This method has been extensively adopted in Europe and America. In addition to his chemical investigations Hargreaves invented an engine which ran on gas-tar and was called the Hargreaves Thermo motor; this was the forerunner of the Diesel engine. Hargreaves died at Widnes on April 4, 1915.

HARIANA, a tract of country in the Punjab, India; a level upland plain, interspersed with patches of sandy soil, and largely overgrown with brushwood. Since the 14th century Hissar has been the local capital. During the troubles which followed the Mogul decline, Haryana was the battlefield of Mahrattas, Bhattis and Sikhs. In 1797–1798 Haryana was overrun by the famous Irish adventurer George Thomas, and in 1803 it passed under British rule. On the conquest of the Punjab Haryana was broken up into the districts of Hissar, Rohtak and Sirsa.

HARINGTON, SIR CHARLES HARINGTON (1872–), British soldier, was born at Chichester on May 31, 1872, and commissioned in the King's (Liverpool) Regiment in 1892. After service in the South African War, he held a series of staff appointments, and on the outbreak of the World War went to France as general staff officer, 2nd grade, of the III. Corps. His ability brought him rapid promotion, and in June 1916 he became major-general, general staff of the II. Army. He remained chief of staff to Gen. Plumer in France for nearly two years, with the exception of a short interval in Italy. The combined talents of the two men were such that the II. Army became proverbial for its excellent staff work and for carrying out any operation with the maximum economy of life. Messines 1917 was perhaps their most brilliant feat. In April 1918 Harington was recalled to the War Office to become deputy chief of the Imperial General Staff. In Sept. 1920 he succeeded General Milne as commander-in-chief of the British forces, and subsequently of the Allied forces at Constantinople and in the Black sea. His tact and diplomacy in a difficult situation, especially during the Chanaq incident, helped to avert serious complications, and was fittingly acknowledged in parliament. In Oct. 1923 he was appointed to the Northern Command, and in 1927 to the Western Command in India. Harington received many honours, including the K.C.B. (1900) and the G.B.E. (1922). He was gazetted full general in 1927.

HARINGTON, SIR JOHN (1561–1612), English writer, Elizabeth's godson, was born at Kelston, near Bath. He studied at Eton and at Christ's college, Cambridge, and c. 1583 was entered at Lincoln's Inn, London. Tradition relates that he translated the story of Giocondo from Ariosto and was reproved by the queen for acquainting her ladies with so indiscreet a selection. He was ordered to retire to his seat at Kelston to complete the translation of the entire work. *Orlando Furioso* in English heroic verse was published in 1591 (reprinted 1607 and 1634).

Harington was high sheriff of Somerset in 1592. In 1596 *The Metamorphosis of Ajax* (reprinted 1927), *An Anatomie of the Metamorphosed Ajax*, and *Ulysses upon Ajax*, were published in succession, the three forming collectively a very absurd and indecorous work of a Pantagruelistic kind. An allusion to Leicester in this book threw the writer into temporary disgrace, but in 1598 he received a commission to serve in Ireland under Essex. He was knighted on the field, to the annoyance of Elizabeth. Harington saved himself from being involved in Essex's disgrace by writing an account of the Irish campaign (printed as *Nugae Antiquae*, volume 1, see below) which increased Elizabeth's anger against the unfortunate earl. Among some papers found in the chapter library at York was a *Tract on the Succession to the Crown* (1602), written by Harington to secure the favour of the new king. In 1605 he even asked for the office of chancellor of Ireland and proposed himself as archbishop in a document known as *A Short View of the State of Ireland written in 1605* (pr. 1879), advocating a policy of generosity and conciliation.

Harington died at Kelston on Nov. 20, 1612. His *Epigrams* were printed in a collection entitled *Alcilia* in 1613, and separately in 1615. His works include *The Englishman's Doctor, Or the School of Salerne* (1608, reprinted 1922), and *Nugae Antiquae* miscellaneous papers collected in 1779.

A biographical account of Harington is prefixed to the Roxburghe Club edition by C. Markham (1880) of his tract on the succession mentioned above.

HARĪRĪ (Abū Maḥmmed ul-Qāsim ibn 'Alī ibn Maḥmmed al-Ḥarīrī, i.e., "the manufacturer or seller of silk") (1054-1122), Arabian writer, was born at Baṣra. He is said to have occupied a government position, but devoted his life to the study of the niceties of the Arabic language. On this subject he wrote a grammatical poem the *Mulḥat ul-'Irāb* (French trans. by L. Pinto, 1885-89; extracts in S. de Sacy's *Anthologie arabe*, 1829); a work on the faults of the educated called *Durrat ul-Ghawwās* (ed. H. Thorbecke, Leipzig, 1871), and some smaller treatises (ed. in Arnold's *Chrestomathy*, pp. 202-9). But his fame rests chiefly on his fifty *maqāmas*. (See ARABIA: Literature, section "Belles Lettres.") These were written in rhymed prose like those of Hamadhānī, and are full of allusions to Arabian history, poetry and tradition, and discussions of difficult points of Arabic grammar and rhetoric.

The *Maqāmas* have been edited with Arabic commentary by S. de Sacy (Paris, 1822, 2nd ed. 1853); with English notes by F. Steingass (1896), English trans. by T. Preston (1850), and another by T. Chénery and F. Steingass (London, 1867 and 1898). Many editions have been published in the East with commentaries, especially with that of Sharīshī (d. 1222).

HARI-RUD, the ancient Arius river of Afghanistan. It rises in the northern slopes of the Koh-i-Baba to the west of Kabul, and finally loses itself in the Tejend oasis north of the Trans-Caspian railway and west of Merv. It runs a remarkably straight course westward through a narrow trough from Daolatyar to Obek, amidst the bleak wind-swept uplands of the highest central elevations in Afghanistan. From Obek to Kuhsan, 50 m. W. of Herat, it forms a valley of great fertility, densely populated and highly cultivated; practically all its waters being drawn off for purposes of irrigation. It is the contrast between the cultivated aspect of the valley of Herat and the surrounding desert that has given Herat its great reputation for fertility. It turns due north and breaks through the Paropamisian hills. Below Kuhsan it receives fresh tributaries from the west. Between Kuhsan and Zulfikar it forms the boundary between Afghanistan and Persia, and from Zulfikar to Sarakhs between Russia and Persia. North of Sarakhs it diminishes rapidly till it is lost in the sands of the Turkman desert. The Hari-Rud marks the only important break existing in the continuity of the central water-parting of Asia.

HARISCHANDRA, in Epic Hindu mythology the 28th king of the Solar dynasty. In his eagerness to have a son he rashly vowed to Varuna that if his prayer were granted he would sacrifice the child to him. The son was born, but Harischandra evaded fulfilment of his vow by vicariously immolating a child purchased by him.

HĀRITH IBN HILLIZA UL-YASHKURĪ, pre-Islamic Arabian poet of the tribe of Bakr, famous as the author of one of the poems generally received among the *Mo'allakāt* (q.v.). Nothing is known of the details of his life.

HARIZI, JUDAH BEN SOLOMON (13th cent.), a Spanish Hebrew poet and traveller. He translated from the Arabic to Hebrew some of the works of Maimonides (q.v.) and also of the Arab poet Ḥariri. His own most considerable work was the *Tahkemoni*, composed between 1218 and 1220.

See on the *Tahkemoni*, Kaempf, *Nicht-andalusische Poesie andalusischer Dichter* (Prague, 1858). In that work a considerable section of the *Tahkemoni* is translated into German.

HARKNESS, ALBERT (1822-1907), American classical scholar, was born at Mendon (Mass.) on Oct. 6, 1822. He graduated at Brown university in 1842, taught for ten years in the Providence high school, studied in Berlin, Bonn (where in 1854 he was the first American to receive the degree of Ph.D.), and Göttingen, and was professor of Greek language and literature in Brown university from 1855 to 1892, when he became professor emeritus. He was one of the founders in 1869 of the American Philological Association, of which he was president in 1875-76, and was a member of the Archaeological Institute's committee on founding the American School of Classical Studies at Athens, of which he served as the second director.

He introduced a new scholarly spirit into American teaching of Latin in secondary schools with a series of Latin text-books. His *Latin Grammar* (1864) and *Complete Latin Grammar* (1898) are his best-known books. He died in Providence (R.I.) on May 27, 1907.

HARLAN, JOHN MARSHALL (1833-1911), American jurist, was born in Boyle county (Ky.), on June 1, 1833. He graduated from Centre college, Danville (Ky.), in 1850, and at the law department of Transylvania university, Lexington, in 1853. He was county judge of Franklin county in 1858-59, was an unsuccessful candidate for Congress on the Whig ticket in 1859, and was elector on the Constitutional Union ticket in 1860.

On the outbreak of the Civil War he recruited and organized the 10th Kentucky U.S. Volunteer Infantry, and served with it as colonel. Retiring from the army in 1863, he was elected by the Union Party attorney-general of the State, and was re-elected in 1865. In 1867 he removed to Louisville to practise law. He was the Republican candidate for governor in 1871 and in 1875, but was defeated on both occasions. He served as a member of the commission which was appointed by President Hayes early in 1877 to accomplish the recognition of one of the two existing State governments of Louisiana (q.v.); and he was a member of the Bering Sea tribunal which met in Paris in 1893.

On Nov. 29, 1877, he became an associate justice of the U.S. Supreme Court, a position which he filled with ability for the remainder of his life. He showed himself a liberal constructionist in opinions on the Civil Rights cases and in the interpretation of the 13th, 14th and 15th Amendments to the Constitution by advocating increasing the power of the Federal Government. He supported the constitutionality of the income-tax clause in the Wilson tariff bill of 1894, and he drafted the decision of the court in the Northern Securities Company case which applied to railways the provisions of the Sherman anti-trust law. In 1889 he became a professor in the Law School of the Columbian university (afterwards George Washington university). He died in Washington (D.C.), on Oct. 14, 1911.

HARLAND AND WOLFF, LIMITED. This shipbuilding and engineering firm was established in 1858, when the shipbuilding works of Robert Hickson and Co. on Queen's Island, Belfast, were acquired by E. J. Harland (afterwards Sir Edward J. Harland, Bart.), who had been Messrs. Hickson's manager, and in 1861 G. W. Wolff became a partner, the firm since then being known as Harland and Wolff. W. H. Wilson and W. J. Pirrie (afterwards Viscount Pirrie), pupils of the original firm, became partners in 1874, and on the death of Sir Edward Harland in 1895 Lord Pirrie became chairman, a position which he occupied until his death in 1924. Viscountess Pirrie was in (1928) president of the company. When Sir Edward Harland started on his own account in 1858 the yard at the Queen's Island covered an area of 3½ ac. and undertook the building of hulls only. Later on the manufacture of machinery was begun, and the firm progressed and extended until (1928) the shipyards and engine works at Belfast covered an area of 220 ac.; in busy times they have given employment to more than 20,000 men.

While the firm's main interests are centred in the establishment at Belfast, they have great shipyards at Govan and Greenock, engineering works and foundries at Glasgow, and ship repairing and engineering works at London, Liverpool and Southampton. The British Admiralty have had a large number of ships built by Harland and Wolff, including cruisers, monitors and destroyers as well as engines for battleships and submarines. The nominal share capital of the company is £12,100,000; the issued capital amounts to £10,340,394. In addition to the many establishments owned directly by the company, they have also controlling interests in steel manufacturing, coal mining and other concerns connected with the supplying of the various materials used in their main business.

HARLAY DE CHAMPVALLON, FRANÇOIS DE (1625-1695), 5th archbishop of Paris, was born in that city on Aug. 14, 1625. Nephew of François de Harlay, archbishop of Rouen, he was presented to the abbey of Jumièges immediately on leaving the Collège de Navarre, and he was only twenty-six

when he succeeded his uncle in the archiepiscopal see. He was transferred to the see of Paris in 1671, he was nominated by the king for the cardinalate in 1690, and the domain of St. Cloud was erected into a duchy in his favour. At first a firm adherent of Mazarin, he is said to have helped to procure his return from exile. He definitely secured the favour of Louis XIV. by his support of the claims of the Gallican Church formulated by the declaration made by the clergy in assembly on March 19, 1682, when Bossuet accused him of truckling to the court like a valet. One of the three witnesses of the king's marriage with Madame de Maintenon, he was hated by her for using his influence with the king to keep the matter secret. He had a weekly audience of Louis XIV. in company with Père la Chaise on the affairs of the Church in Paris, but his influence gradually declined. He urged the revocation of the edict of Nantes, and showed great severity to the Huguenots at Dieppe, of which he was temporal and spiritual lord. He died on Aug. 6, 1695.

See Abbé Legendre, *Vita Francisci de Harlay* (Paris, 1720) and *Éloge de Harlay* (1695); Saint-Simon, *Mémoires* (vol. ii, ed. A. de Boislisle, 1879), and numerous references in the *Lettres* of Mme. de Sévigné.

HARLECH, ancient capital of Merionethshire, Wales, 38 m. from Aberystwyth by G.W.R. Pop. (1921) 1,096. (Parish of Llandanwg). Ruins of a fortress crown the rock of Harlech, about half a mile from the sea. Roman coins have been discovered in the neighbourhood and there are associations with Bronwen, daughter of Bran Fendigaid, and the Mabinogion generally. In the 10th century, Harlech castle was, apparently, repaired by Colwyn, lord of Ardudwy, and thence called Caer Colwyn. The present structure dates from 1285 and is a good example of an Edwardian concentric castle. Edward made Harlech a free borough. Owain Glyn Dwr held it for four years. Dafydd ap Ieuan ap Einion held it for the Lancastrians, until famine made him surrender to Edward IV. From this time is said to date the air *Rhyfelgyrch gwyr Harlech*. The castle was the last to be held for the king in the civil war. The town is a tourist centre. In 1927 Coleg Harlech was established, for adult education on a residential basis.

HARLEQUIN, in modern comedy and pantomime, the posturing and acrobatic character with masked face, shaven head, and attired in parti-coloured and spangled tights; he is provided with a sword like a bat, or lath, with which he works wonders. The term is not now used in the special sense that characterized the original harlequin; it is used in a more or less general way to signify a person who makes funny moves and cuts amusing capers—not unlike those of the clown (*q.v.*).

HARLEQUIN CABBAGE BUG (*Murgantia histrionica*), an American heteropterous insect of tropical or subtropical origin, belonging to the family Pentatomidae. This insect is a native of Mexico and Central America. It made its appearance in Texas in 1864, and in a way repeated the history of the Colorado potato beetle; it found an abundance of cultivated cabbages, multiplied rapidly, and quickly spread. It appeared in North Carolina in 1867; in 1870 it was found in Missouri and Tennessee; in 1876 it reached Delaware; in 1892 it was injurious in New Jersey, and in 1894 it was found on Long Island. At present it is destructive throughout the entire South as far north as tide-water Virginia. North of this point it is only occasionally injurious, apparently being killed by severe winters, reinventing the territory later. It is a brilliantly coloured red-and-black plant-bug, about half an inch in length, and is known by several common names, such as calico-back, fire-bug and terrapin-bug. It sucks the sap from the leaves and leaf-veins of cabbage and other cruciferous crops, causing the plants to wilt and die. A small plant will be killed in a day or so, and as many as 50 or 60 mature bugs are often found on a large plant. It is supposed to hibernate in the adult condition. The barrel-shaped eggs, white-and-black in colour, are laid in double rows on the leaves. The young are active and resemble the adults except that they are wingless. They moult five times before reaching full growth. In the South there may be several generations annually, probably four or five. It is a difficult insect to fight, since insecticide applications that will kill it also injure the plants. Clean-cultural methods, especially a thorough

cleaning-up of the fields during the winter time; the use of trap crops of mustard or other cruciferous plants in the spring, on which the insects may be killed by oil applications, the trap-crops themselves being of no value; and hand-picking, are the methods recommended. On trap-crops in the spring, they may be destroyed by hand-torches. (L. O. H.)

HARLEQUIN-FLY, the popular name of small flies of the genus *Chironomus*. The larvae, known as bloodworms, are aquatic and live in foul or very deep water where there is little oxygen. To enable them to utilize fully the scant supply of oxygen, these larvae possess in their blood the same red pigment, haemoglobin, that is found in vertebrates. (See DIPTERA; COLOUR OF ANIMALS; DISTRIBUTION OF ANIMALS.)

HARLESS (originally HARLES), **GOTTLIEB CHRISTOPH** (1738–1815), German classical scholar and bibliographer, was born at Culmbach in Bavaria on June 21, 1738, and died at Erlangen on Nov. 2, 1815, where he had been professor for 45 years. His numerous classical editions are now superseded, but he will be remembered for his chief work, the new edition of Fabricius' *Bibliotheca Graeca* (12 vols., 1790–1809).

His life was written by his son, Johann Christian Friedrich Harless (1818).

HARLINGEN, a seaport in the province of Friesland, Holland, on the Zuider Zee, and the terminus of the railway and canal from Leeuwarden (15½ m. E.). Pop. (1926) 10,071. Harlingen has become the most considerable seaport of Friesland since the construction of the outer harbour in 1870–77, and in addition to railway and steamship connection with Bremen, Amsterdam, and the southern provinces there are sailings to Hull and London. Sluices protect the inner harbour from the high tides. The only noteworthy buildings are the town hall (1730–33) and the West church, which consists of a part of the former castle of Harlingen. The chief trade of Harlingen is the exportation of Frisian produce, namely, butter and cheese, meat, flax, fish, potatoes, etc. There is also a considerable import trade in timber, coal, manufactured cotton, hemp and jute for the Twente factories.

HARLINGEN, a rapidly growing city of Cameron county, Texas, U.S.A., 28m. N.W. of Brownsville, on Federal highway 96, and served by the Missouri Pacific and the Southern Pacific railways. The population in 1920 was 1,784, and in 1928 was estimated locally at 13,500. It is an important distributing centre for the irrigated lands of the Lower Rio Grande valley, and there are cotton gins and compresses and other industries. Harlingen was settled about 1904 and incorporated in 1910.

HARMATTAN (har-māt-tān'), a hot, dry desert wind between November and March on the coast of Upper Guinea, often bringing clouds of red dust which form a dense haze and impede river navigation. Locally, the wind is termed "the Doctor" for, notwithstanding its disadvantages, it forms a welcome relief from the damp heat of the previous season.

HARMINE, an alkaloid of the formula $C_{13}H_{12}ON_2$ (see CHEMISTRY: *Organic, Heterocyclic Division*).

HARMODIUS (Gr. har-mōd-i-ös), a handsome Athenian youth, friend of Aristogeiton. Hipparchus, the younger brother of the tyrant Hippias, endeavoured to supplant Aristogeiton in the good graces of Harmodius, but, failing in the attempt, revenged himself by putting a public affront on Harmodius's sister at a solemn festival. Thereupon the two friends conspired with a few others to murder both the tyrants during the armed procession at the Panathenaic festival (514 B.C.). Seeing one of their accomplices speaking to Hippias, and imagining that they were being betrayed, they prematurely attacked and slew Hipparchus alone. Harmodius was cut down on the spot by the guards, and Aristogeiton was soon captured and tortured to death. When Hippias was expelled (510), Harmodius and Aristogeiton became the most popular of Athenian heroes; their descendants were exempted from public burdens, and had the right of public entertainment in the Prytaneum, and their names were celebrated in popular songs and scolia (after-dinner songs) as the deliverers of Athens. One of these songs, attributed to a certain Callistratus, is preserved in Athenaeus (p. 695). Their statues by Antenor in the agora were carried off by Xerxes and replaced by new ones by Critius and

Nesiotes. Alexander the Great afterwards sent back the originals to Athens. It is not agreed which of these was the original of the marble tyrannicide group in the museum at Naples.

HARMONIA, in Greek mythology, according to one account the daughter of Ares and Aphrodite, and wife of Cadmus. When the government of Thebes was bestowed upon Cadmus by Athena, Zeus gave him Harmonia to wife. All the gods honoured the wedding with their presence. Cadmus (or one of the gods) presented the bride with a robe and necklace, the work of Hephaestus. This necklace brought misfortune to all who possessed it; it led to the death of Amphiarus, of Eriphyle, of Alcmaeon, of Phegeus and his sons. Even in historic times its baleful influence continued. Phayllus, one of the Phocian leaders in the Sacred War (352 B.C.) carried it off and gave it to his mistress. After she had worn it for a time her son was seized with madness and set fire to the house, and she perished in the flames. Both Harmonia and Cadmus were ultimately turned into snakes after a life of misfortunes. Other accounts make Harmonia daughter of Zeus and Electra (the Pleiad), or allegorize her as a personification of concord.

See Preller-Robert (index, s.v.) and the classical dictionaries.

HARMONIC. In acoustics, a harmonic is a secondary tone which accompanies the fundamental or primary tone of a vibrating string, reed, etc.; the more important are the 3rd, 5th, 7th, and octave (see SOUND; HARMONY).

For Harmonics in mathematics see SPHERICAL HARMONICS.

HARMONICA, a generic term applied to musical instruments in which sound is produced by friction upon glass bells. The word is also used to designate instruments of percussion of the Glockenspiel type, made of steel and struck by hammers (Ger. *Stahlharmonika*).

The origin of the glass-harmonica tribe is to be found in the fashionable 18th century instrument known as musical glasses (Fr. *verrillon*), the principle of which was known already in the 17th century. The *verrillon* or *Glassspiel* consisted of 18 beer glasses arranged on a board covered with cloth, water being poured in whenever it was found necessary in order to alter the pitch, and the sound being produced by passing the moistened finger round the rims. (Or sometimes the sides of the glasses were struck instead by wooden sticks.) Gluck gave a concert at the "little theatre in the Haymarket" (London) in April 1746, at which he performed on musical glasses a concerto of his composition with full orchestral accompaniment.

When Benjamin Franklin visited London, in 1757, he was so much struck by the possibilities of the glasses as musical instruments that he set to work on a mechanical application of the principle involved, the result being the glass harmonica finished in 1762. The instrument was for many years in great vogue. Mozart, Beethoven, Naumann and Hasse composed music for it, while it had its celebrated virtuosi, such as Marianne Davies and Marianna Kirchgessner.

The curious vogue of the instrument, as sudden as it was ephemeral, produced emulation in a generation unsurpassed for zeal in the invention of musical instruments. The most notable of its offspring were Carl Leopold Röllig's improved harmonica with a keyboard in 1786, Chladni's euphon in 1791 and clavicylinder in 1799, Ruffelsen's melodicon in 1800 and 1803, Franz Leppich's panmelodicon in 1810, and Buschmann's uranion in the same year. Most of these have long since completely disappeared, but many specimens of the Franklin type are still preserved, one being in the Victoria and Albert Museum, London. It may be added, moreover, that instruments of the latter type are still in use in humble circles, being played by itinerant performers in the streets and elsewhere.

For the steel harmonica see GLOCKENSPIEL.

HARMONIC ANALYSIS. Many physical phenomena, such as sound waves, alternating electric currents, tides, machine motions, etc., may be periodic in character. Such motions can be measured at a number of successive values of the independent variable, usually the time; and these data, or a curve plotted from these data, will represent a function of that independent variable. Thus the ordinate of the curve at any point is

$$y=f(x).$$

Generally the mathematical expression for $f(x)$ will be unknown. However, with the periodic functions to be found in nature, $f(x)$ can be expressed as the sum of a number of sine and cosine terms. Such a sum is known as a Fourier series (q.v.) and the determination of the coefficients of these terms is called *harmonic analysis*. The term harmonic analysis can also be used in the

FIG. 1

broader sense of the analysis into any kind of periodic components, such as spherical harmonics, cylindrical harmonics, tesseral harmonics, etc. However, in this treatment we shall confine ourselves to the development into Fourier series, which development has found more extensive practical application than any of the others. One of the terms of such a series has a period equal to that of $f(x)$ and is called the *fundamental*. Other terms have shorter periods, which are aliquot parts of the fundamental. These are called *harmonics*.

Applications.—Harmonic analysis is of great value in mathematics, in physics, and in engineering. A sound wave, for instance, can cause the vibration of a thin diaphragm, whose motion is photographed in the form of a continuous curve by the use of the Phonodeik of D. C. Miller, or by other methods. The shape of the resulting curve will depend on the quality of the sound and will generally be quite complicated. However, it can be analysed into its fundamental and harmonics or overtones by use of Fourier series. It is the number and magnitude of these harmonics which determine the quality of the sound, and therefore such investigations are of great value in the scientific study of music and speech. Similar methods are used extensively by the electrical engineer in the study of alternating currents. In mechanical engineering they can be used in the investigation of valve motion and other mechanical movements. Harmonic analysis is also used in the study of tidal records; and, by the use of such information as it affords, the prediction of tides is possible. (See TIDES.)

All the above applications have been for cases where the movements are truly periodic. In a large class of other phenomena, such as the weather, sun spots, magnetic deviations, river flow, atmospheric strays in radio reception, etc., the fundamental period is usually not evident and the periods of the harmonics are not aliquot parts of the fundamental. Even in such cases, however, modified methods are being used to some extent, the analysis still being made into a series of sine or cosine terms.

Any ordinary non-periodic curve of finite length can also be analysed by the harmonic method, the scale being changed in the x -direction so that the length is 2π units. An example taken from D. C. Miller's excellent book, *The Science of Musical Sounds*, is shown in fig. 1a, where a profile is analyzed and found to have the equation:

$$\begin{aligned} y = & 49.6 \sin(\theta + 302^\circ) + 17.4 \sin(2\theta + 298^\circ) \\ & + 13.8 \sin(3\theta + 195^\circ) + 7.1 \sin(4\theta + 215^\circ) \\ & + 4.5 \sin(5\theta + 80^\circ) + 0.6 \sin(6\theta + 171^\circ) \\ & + 2.7 \sin(7\theta + 34^\circ) + 0.6 \sin(8\theta + 242^\circ) \\ & + 1.6 \sin(9\theta + 331^\circ) + 1.3 \sin(10\theta + 208^\circ) \\ & + 0.3 \sin(11\theta + 89^\circ) + 0.5 \sin(12\theta + 229^\circ) \\ & + 0.7 \sin(13\theta + 103^\circ) + 0.3 \sin(14\theta + 305^\circ) \\ & + 0.4 \sin(15\theta + 160^\circ) + 0.5 \sin(16\theta + 230^\circ) \\ & + 0.5 \sin(17\theta + 207^\circ) + 0.4 \sin(18\theta + 64^\circ). \end{aligned}$$

These harmonics were then combined, giving the result shown in fig. 1b.

Numerical Methods.—In 1822 Fourier showed that a function $y=f(x)$ could be expressed between the limits of $x=0$ and $x=2\pi$ by the series:

Measured ordinates	Sums	Diffs.		Sine terms		Cosine terms	
				1st and 5th	3rd	1st and 5th	3rd
y_1	S_1	d_0	$\sin 30^\circ$	S_1		d_2	
y_2	S_2	d_1	$\sin 60^\circ$	S_2		d_1	
y_3	S_3	d_2	$\sin 90^\circ$	S_3	$S_1 - S_3$	d_0	$d_0 - d_2$
				$S_0 = \frac{S_e}{3}$	$S = \frac{S}{3}$	$D_0 = \frac{D_e}{3}$	$D = \frac{D}{3}$
				$a_1 = \frac{S_0 + S_e}{3}$	$a_3 = \frac{S}{3}$	$b_1 = \frac{D_0 + D_e}{3}$	$b_3 = \frac{D}{3}$
				$a_5 = \frac{S_0 - S_e}{3}$		$b_5 = \frac{D_0 - D_e}{3}$	

$$y = a_1 \sin x + a_2 \sin 2x + a_3 \sin 3x + \dots + b_0 + b_1 \cos x + b_2 \cos 2x + \dots \quad (1)$$

provided the function is single-valued, finite, and continuous, or at least with a finite number of discontinuities. The coefficients are

$$\left. \begin{aligned} b_0 &= \frac{1}{2\pi} \int_0^{2\pi} y dx \\ b_k &= \frac{1}{\pi} \int_0^{2\pi} y \cos kx dx \\ a_k &= \frac{1}{\pi} \int_0^{2\pi} y \sin kx dx \end{aligned} \right\} \quad (2)$$

where $k=1, 2, 3, \dots$

Equation (1) can be written in the alternate form:

$$y = c_1 \sin(x + \phi_1) + c_2 \sin(2x + \phi_2) + c_3 \sin(3x + \phi_3) + \dots, \quad (3)$$

where

$$c_k = \sqrt{a_k^2 + b_k^2}, \quad \phi_k = \tan^{-1} \frac{b_k}{a_k} \quad (4)$$

Assume that a record has been obtained of some periodic phenomenon expressed as a curve or as a set of data which can be plotted and called $f(x)$. Even although $f(x)$ cannot be expressed as a simple function, equation (1) can be used to represent it, and the coefficients a_k and b_k can be determined. It will be necessary first to find the period of the function; that is, the distance between corresponding points on successive waves. This distance will be called 2π radians or 360° , and can then be divided into any convenient number of parts, say n . The first n ordinates are measured and their values substituted in equation (1), giving n equations in the n undetermined coefficients. These equations can be solved to obtain a_k and b_k . The n equations have the form:

$y_k = b_0 + b_1 \cos x_k + b_2 \cos 2x_k + \dots + a_1 \sin x_k + a_2 \sin 2x_k + \dots$, where $k=0, 1, 2, 3, \dots, (n-1)$ successively; y_k is the k th ordinate of the curve, and x_k is the corresponding abscissa expressed in degrees. From these it can be shown that

$$\left. \begin{aligned} b_0 &= \frac{1}{n} (y_0 + y_1 + y_2 + \dots + y_{n-1}), \\ b_k &= \frac{2}{n} (y_0 \cos kx_0 + y_1 \cos kx_1 + \dots + y_{n-1} \cos kx_{n-1}), \\ a_k &= \frac{2}{n} (y_0 \sin kx_0 + y_1 \sin kx_1 + \dots + y_{n-1} \sin kx_{n-1}). \end{aligned} \right\} \quad (5)$$

A curve plotted from (1) using the coefficients (5) will pass through all the values y_k exactly, but probably will not coincide with the experimental curve at other points. Obviously, the use of a larger number of terms will increase the accuracy. In some applications the function can be very closely approximated by a few terms. In other cases, particularly if the wave has sharp corners, a large number of terms is necessary to get a sufficiently accurate expression. It is often possible to tell something about the coefficients by inspection, thus simplifying the mathematical work of analysis. If positive and negative loops of the curve are the same, then even harmonics are absent. This is practically always the case with alternating currents. Also, if the curve for $x < 0$ is the reflection in the y -axis of the curve for $x > 0$, there will be no sine terms; while if the curve is symmetric about the origin, there are no cosine terms.

Schedule Methods.—The use of equation (5) is the basis of numerous so-called *schedule methods* of analysis. These are merely short cuts for solving the equations (5), many of the routine multiplications being combined and tabulated in a schedule. Of these, the best-known is probably that of Runge. It can best be explained by an example. For this a six-point schedule has been selected. Only odd harmonics are considered, and the zero is taken where the curve crosses the x -axis. Then the six equations are:

$$\begin{aligned} 3b_1 &= y_1 \cos 30^\circ + y_2 \cos 60^\circ + y_3 \cos 90^\circ + y_4 \cos 120^\circ + y_5 \cos 150^\circ, \\ 3b_3 &= y_1 \cos 90^\circ + y_2 \cos 180^\circ + y_3 \cos 270^\circ + y_4 \cos 360^\circ + y_5 \cos 450^\circ, \\ 3b_5 &= y_1 \cos 150^\circ + y_2 \cos 300^\circ + y_3 \cos 450^\circ + y_4 \cos 600^\circ + y_5 \cos 750^\circ, \\ 3a_1 &= y_1 \sin 30^\circ + y_2 \sin 60^\circ + y_3 \sin 90^\circ + y_4 \sin 120^\circ + y_5 \sin 150^\circ, \\ 3a_3 &= y_1 \sin 90^\circ + y_2 \sin 180^\circ + y_3 \sin 270^\circ + y_4 \sin 360^\circ + y_5 \sin 450^\circ, \\ 3a_5 &= y_1 \sin 150^\circ + y_2 \sin 300^\circ + y_3 \sin 450^\circ + y_4 \sin 600^\circ + y_5 \sin 750^\circ. \end{aligned}$$

All can be expressed as functions of 30° , 60° , and 90° degrees:

$$\begin{aligned} 3b_1 &= (y_2 - y_4) \sin 30^\circ + (y_1 - y_5) \sin 60^\circ, \\ 3b_3 &= -(y_2 - y_4) \sin 90^\circ, \\ 3b_5 &= (y_2 - y_4) \sin 30^\circ - (y_1 - y_5) \sin 60^\circ, \\ 3a_1 &= (y_1 + y_5) \sin 30^\circ + (y_2 + y_4) \sin 60^\circ + y_3 \sin 90^\circ, \\ 3a_3 &= (y_1 - y_3 + y_5) \sin 90^\circ, \\ 3a_5 &= (y_1 + y_5) \sin 30^\circ - (y_2 + y_4) \sin 60^\circ + y_3 \sin 90^\circ. \end{aligned}$$

It will be noticed that, except for y_3 , all the coefficients occur as sums or differences. In the schedule given above, y_0 has been added so that the curve does not have to cross the x -axis at $x=0$. If $f(x)=0$ when $x=0$, as in the previous equations, then of course y_0 disappears. The work can be tabulated as shown above. A numerical example given by Grover is as follows:

	Ordinates	Sums	Diffs.		Sine terms		Cosine terms	
					1st and 5th	3rd	1st and 5th	3rd
0	-1.3		-1.3					
1	15.1	32.4	-2.2	0.50	+16.200		-0.425	
2	28.0	56.85	-0.85	0.86	-49.233	32.400	-1.905	-1.300
3	32.35	32.35		1.00	32.350	32.350	-1.300	0.850
		Sums			48.550	49.233	1.725	1.905
		S_e			49.233	-0.683	1.905	0.180
		$a_1 =$			97.783		-3.630	
					32.594		$b_1 = -1.210$	$b_3 = -0.150$
					$a_5 = -0.228$		$a_3 = 0.017$	$b_5 = 0.060$

This has been plotted in fig. 2. The heavy curve is the one to be analyzed. The six points used in the above schedule are enclosed by circles. Since the wave is nearly sinusoidal, the analysis results in a large fundamental sine curve and very small higher harmonics. Synthesis gives the light curve of fig. 2. It will be noted that this passes through all six points, but obviously it cannot be expected to coincide with the original curve throughout. By

FIG. 2

taking a larger number of points and, therefore, a different schedule, a much closer approximation would be obtained.

A method of selected ordinates has been devised by Fischer-Hinnen. This appears to require slightly less computation than the Runge method, but has the disadvantage that a new set of equally-spaced ordinates must be measured for each pair of coefficients. Other methods of computation of the coefficients have been worked out by Steinmetz, S. P. Thompson and others. Various graphical methods have also been devised. C. S. Slichter, for instance, uses a special graph paper which introduces the sine or cosine factor without computation. The area under the curve is measured with an ordinary planimeter. It requires the replotting of the curve for each coefficient, and it is doubtful if any time is saved over the schedule method. Other graphical methods have been used by Clifford, Perry, Harrison, Ashworth, Beattie and Rottenburg.

Mechanical Methods.—The above methods all require a large amount of labour, especially if many coefficients are to be determined. If much of the work is to be done, therefore, some machine method is advisable. Equation (2) is used in most of the mechanical analyzers.

If the curve $y=f(x)$ of fig. 3a is to be analyzed, it is merely necessary to multiply the ordinates by $\sin x$ (fig. 3b) and obtain the area under the resulting curve (fig. 3c). This gives $\int_0^{2\pi} f(x) \sin x dx$, which is proportional to a_1 . The other coefficients are obtained similarly. Most of the machines, therefore, consist of some means of multiplying the ordinates of the curve by $\sin kx$ or $\cos kx$ and integrating the product. (See MATHEMATICAL INSTRUMENTS.)

The first mechanical harmonic analyzer was proposed by Lord Kelvin, who made use of an integrator invented by his brother, J. Thomson. The integrator consists of a disc D, a sphere S, and a cylinder C, as shown in fig. 4. The sphere rolls along a diameter of the disc so that when it is in the centre of D it will be unaffected by the rotation of D. At any other point it will turn an amount proportional to its distance from the centre of D.

This motion is communicated to the cylinder. Pure rolling motion is used throughout, a principle which Kelvin considered very important.

In the Kelvin harmonic analyser the sphere S is rolled back and forth along the disc by an amount equal to the ordinates of the curve being traced. Therefore, if the sphere is a distance r

FIG. 4

from the centre of D, $r=f(x)$. At the same time the disc is given a sinusoidal motion. Thus, if the curve moves a distance dx ,

the disc will turn through an angle $C \begin{Bmatrix} \cos kx \\ \sin kx \end{Bmatrix} dx$ where C is a

constant dependent on the construction of the apparatus. The distance moved by a point on the surface of the cylinder is

$$rC \begin{Bmatrix} \cos kx \\ \sin kx \end{Bmatrix} dx = C f(x) \begin{Bmatrix} \cos kx \\ \sin kx \end{Bmatrix} dx.$$

If the curve is traced for a complete period, the total displacement of a point on the surface of the cylinder is

$$C \int_0^{2\pi} f(x) \begin{Bmatrix} \cos kx \\ \sin kx \end{Bmatrix} dx$$

which, by (2), is proportional to the k th sine or cosine coefficient. By having a number of such units side by side several coefficients can be obtained at once. The spheres are all moved together an amount equal to the ordinates of the curve, while the discs are turned through angles which are exact multiples of each other.

Another machine working on a similar principle is that invented by Henrici and developed by Coradi. This very beautiful instrument makes use of a number of glass spheres which are moved an amount equal to the ordinate of the curve. The readings are obtained by two Amsler integrating wheels bearing on each sphere, one reading sine components, and the other, cosine components. A five-sphere machine will thus give ten coefficients for one trace of the curve. The machine is speedy and accurate, but its expense and delicacy have limited its use to some extent. The Michelson and Stratton analyzer will handle up to eighty coefficients at once. It works equally well as a synthesizer and has been extensively used in tide prediction. The Chubb analyzer differs from all others in that it uses a polar graph instead of a rectangular one. The curve, in the form of a cardboard template, is fastened to the table of the machine. The table moves back and forth with a sinusoidal motion as it turns, and the result is integrated by an ordinary planimeter. The machine can evaluate only one coefficient at a time and is therefore slow. It is very rugged, and finds considerable use in connection with polar oscillograms.

A product integrator, recently developed at the Massachusetts Institute of Technology, obtains the integral of the product of any two curves. Its primary use is in the mechanical solution of differential equations, but obviously it can be used for harmonic analysis. In fact, it will develop curves in terms of various other series as well as the harmonic series of Fourier. Many other machines have been proposed, notably by Mader, Rowe, Wiechert and Sommerfeld, Bashforth, Yule, Le Conte, Terada, Dellenbaugh and Woodbury. Most of these machines work on the principle previously mentioned, though the Dellenbaugh uses the schedule method, while the Woodbury is based on the Fischer-Hinnen method.

FIG. 3

Direct Analysis.—All the above methods make use of an experimentally-determined curve or set of data. In the case of electric currents or voltages, an entirely different method is possible. This direct method was suggested by Pupin in 1894, and has been developed recently by the Bell System laboratories. Instead of first getting an oscillographic record of the voltage or current and then analyzing it mathematically, the analysis is performed directly on the electric quantity by making a record of the response when the natural frequency of a tuned circuit is varied through a wide range.

A large number of methods are available for the harmonic analysis of complex waves. The direct mathematical method is unnecessarily long and arduous. This has been simplified by schedules which are fairly quick and are the methods generally used if only a small amount of such work is to be done. If much harmonic analysis is required, it is advisable to use a machine analyzer, such as the Henrici-Coradi, the Michelson and Stratton, or the Chubb. Of these the first appears to offer advantages, if five or ten coefficients are sufficient. If a very large number of terms is required, the Michelson and Stratton is advisable.

The reverse process of *synthesis* is also used to a considerable extent, particularly in tide prediction. Various machines have been built for this purpose, the first being designed by Kelvin. An extremely compact form of Kelvin synthesizer was built by D. C. Miller for use in his work on the theory of musical sounds. The Michelson and Stratton machine is also very good for synthesis. In fact, any of the analyzers can be used for this purpose, though some are much more convenient than others.

HARMONICHORD, an ingenious kind of upright piano, in which the strings were set in vibration not by the blow of a hammer but by friction. One of the many attempts to fuse piano and violin, the harmonichord was invented by Johann Gottfried and Johann Friedrich Kaufmann (father and son) in Saxony at the beginning of the 19th century. The space under the keyboard was enclosed, a knee-hole being left in which were two pedals used to set in rotation a large wooden cylinder fixed just behind the keyboard over the levers. The cylinder (in some specimens covered with chamois leather) tapered towards the treble-end. When a key was depressed, a little tongue of wood, one end of which stopped the string, was pressed against the revolving cylinder, and the vibrations produced by friction were transmitted to the string and reinforced as in piano and violin by the sound-board. Carl Maria von Weber must have had some opinion of the possibilities of the harmonichord, since he composed for it a concerto with orchestral accompaniment.

HARMONIUM, a wind, keyboard instrument, otherwise a small organ without pipes, furnished with free reeds. Both the harmonium and its later development, the American organ, are known as free-reed instruments, the musical tones being produced by tongues of brass, technically termed "vibrators." The vibrator is fixed over an oblong, rectangular frame, through which it swings

freely backwards and forwards like a pendulum while vibrating, whereas the beating reeds (similar to those of the clarinet family), used in church organs, cover the entire orifice, beating against the sides at each vibration. A reed or vibrator, set in periodic motion by impact of a current of air, produces a corresponding succession of air puffs, the rapidity of which determines the pitch of the musical note. There is an essential difference between the harmonium and the American organ in the direction of this current; in the former the wind apparatus forces the current upwards, and in the latter sucks it downwards, whence it becomes desirable to separate in description these varieties of free-reed instruments.

Harmonium.—This has a keyboard of five octaves compass when complete, and a simple action controlling the valves, etc. The necessary pressure of wind is generated by bellows worked by the feet of the performer upon foot-boards or treadles. The air is thus forced up the wind-trunks into an air-chamber called the wind-chest, the pressure of it being equalized by a reservoir, which receives the excess of wind through an aperture, and permits escape, when above a certain pressure, by a discharge valve or pallet. The aperture admitting air to the reservoir may be closed by a drawstop named "expression." The air being thus cut off, the performer depends for his supply entirely upon the management of the bellows worked by the treadles, whereby he regulates the compression of the wind. The character of the resulting tone is then entirely changed from a mechanical response to the player's touch to an expressive one, varying in correspondence with the increase or diminution of sound through the greater or less pressure of wind to which the reeds may be submitted. The drawstops bearing the names of the different registers in imitation of the organ, admit, when drawn, the wind from the wind-chest to the corresponding reed compartments, shutting them off when closed.

American Organ.—This acts by wind exhaustion. A vacuum is practically created in the air-chamber by the exhausting power of the footboards, and a current of air thus drawn downwards passes through any reeds that are left open, setting them in vibra-

tion. Valves in the board above the air-chamber give communication to reeds made more slender than those of the harmonium and more or less bent, while the frames in which they are fixed are also differently shaped, being hollowed rather in spoon fashion. The channels, the resonators above the reeds, are not varied in size or shape as in the harmonium; they exactly correspond with the reeds, and are collectively known as the "tubeboard." The American organ has a softer tone than the harmonium. The "automatic swell" in the instruments of Mason and Hamlin (of Boston, U.S.A.), is a contrivance which assists expression. Another very clever improvement introduced by these makers, who were the originators of the instrument itself, is the "vox humana," effected by a fan, made to revolve rapidly by a wind pressure; its rotation, disturbing the air near the reeds, causes interferences of vibration that produce a tremulous effect, not unlike the beatings heard from combined voices, whence the name.

FROM G. KINSKY, "CATALOGUE OF THE HERGER MUSIKHISTORISCHES MUSEUM"
THE HARMONICHORD, A KIND OF PIANOFORTE IN WHICH SOUND WAS OBTAINED BY THE FRICTION OF A CYLINDER TURNED BY PEDALS

History.—The start in the instrument's invention was due to Prof. Christian Gottlieb Kratzenstein of Copenhagen, who having had the opportunity of examining a Chinese cheng sent to his native city, invented about 1779, a small pneumatic organ fitted with free reeds which appears to have been the first instrument of its kind.

During the first half of the 19th century numerous efforts in

France and Germany, and subsequently in England, were made to produce new keyboard instruments with free reeds, the most notable of these being the physharmonica of Anton Häckel, invented in Vienna in 1818, which, improved and enlarged, has retained its hold on the German people. The modern physharmonica is a harmonium without stops or percussion action; it does not therefore speak readily or clearly. It has a range of five or six octaves. Other instruments of similar type are the French melophone and the English seraphine, a keyboard harmonica with bellows but no channels for the tongues, for which a patent was granted to Myers and Storer in 1839; the aeoline or aelodicon of Eschenbach; the melodicon of Dietz; the melodica of Rieffelson; the apollonicon; the new cheng of Reichstein; the terpodion of Buschmann, etc. But none of these has survived.

HARMONY. In its earliest English sense the term harmony, in music, is applied to any pleasing arrangement of musical sounds; but technically it is confined to the science of the simultaneous combination of sounds of different pitch, without regard to their quality of tone or *timbre*, a matter which belongs to the province of instrumentation (*q.v.*). The sense of the word harmony is further restricted to the study of combinations rather as blocks of sound than as textures. The fundamental aesthetic texture of harmony is counterpoint (*q.v.*).

But while the abstraction of harmony from instrumentation is as legitimate and necessary as the abstraction of draughtmanship from colour, the abstraction of harmony from counterpoint cuts music adrift from its foundations and leads to no better results than the abstraction of sound from sense. Harmony is to classical music what perspective is to pictorial art. But visual perspective is a science, whereas this musical perspective is wholly an art. The present article aims at showing that its laws are true to the nature of art and are no mere rules of a game. But we must not impute the meaning of its laws to any music earlier than the 14th century, and even in the spacious days of Elizabeth and Palestrina there are many things in harmony which do not mean what we would mean by them to-day.

I. ORIGINS OF CONCORD AND DISCORD

The diatonic major scale (or something very like it) may be found by playing eight successive white notes from C to C on the pianoforte. It would be better to accept this as a scientific definition than to begin the study of harmony with questions like that as to whether the first hen preceded or followed the first egg. The interesting fact is that the ancient Greeks showed a latent harmonic sense by developing the diatonic scale that has proved itself capable of bearing our classical system of harmony. In the article *MUSIC* the origin of scales is touched upon; in the meantime we may assume that eggs are eggs without waiting for the latest researches of bio-chemistry.

The one ostensible effort the Greeks made at organizing simultaneous notes of different pitch was the practice of *magadizing*. The magadis was a stringed instrument with a bridge that divided the strings at two-thirds of their length. The shorter portion of the string then sounded an octave higher than the longer. To magadize, therefore, was to get the voices of children or women to sing in octaves above the voices of men.

Now we may begin our survey of harmonic combinations with two propositions. First, any two notes an octave apart are harmonically identical. From this we may draw two useful inferences—first, that doubling in octaves never was and never will be a process of harmonization; and, secondly, that a combination does not change its meaning by the addition or subtraction of an octave.

The second fundamental proposition is that harmonies are built upwards from the bass. This will be denied by some theorists; but the present line of thought is not an *a priori* theory, but the observation of facts. By “low” notes we mean sounds produced by slow vibrations, and by “high” notes sounds produced by rapid vibrations.

The harmonic identity of notes an octave apart was a matter of physical sensation before the dawn of history. In 1862 Helmholtz explained it and a great many other facts in musical aesthetics. He solemnly warned musical theorists against hastily apply-

ing his scientific results to the art of music, and warned them in vain. But we may safely draw some inferences from his discovery that the *timbre* of a note depends upon the selection and proportion of a series of overtones in the vibration-ratios of aliquot parts of the fundamental note. Thus, a note adds nothing to a lower note if it is at the distance of an overtone; except in that if the distance is not exactly one or more octaves the combination will assume the harmonic sense of its difference from an octave; thus, a 12th is equivalent to a 5th.

Distances of pitch, it may here be explained, are called intervals. They are reckoned (numerically and inclusive of both notes) up a diatonic scale. From the fundamental (or tonic) note of a major scale (as from C on the white notes of the pianoforte) all intervals within that scale are *major*, and the 4th, 5th and octave are called *perfect*. Intervals a semitone less than major are called *minor*, except in the case of perfect intervals, which become *imperfect* or *diminished* when reduced by a semitone. Otherwise a diminished interval is a semitone less than minor. An augmented interval is a semitone greater than major. The terms “augmented” and “diminished” should be applied only to *chromatic* intervals, that is to say, to intervals of which one note is foreign to the scale of reference. There is in every scale one 4th that is greater than perfect (F to B in the scale of C) and one imperfect 5th (B to F). This diatonic enlarged 4th is called the *tritone*. Intervals are “inverted” by raising the lower note to a higher octave; thus the imperfect 5th is the inversion of the tritone 4th.

Helmholtz's discovery of the nature of timbre proves that certain aspects of harmony are latent in nature. Conversely, the art of harmony constantly produces effects of timbre apart from those of the particular instruments in use. But musical elements interact in ways that quickly carry musical aesthetics into regions far removed from any simple relation between harmony and timbre. What acoustics can tell us of concord and discord is not only inadequate for our musical experience, but contrary to it. Acoustics tell us that the rapid “beats” that distress the ear in harsh combinations are due to the periodic reinforcements and weaknesses that occur as the waves get in and out of phase with each other. When these beats are so rapid as to produce a note of their own, this resultant tone may or may not be pleasant; the painful stage of beats is that in which they are noticeable, as a flickering light is noticeable. Combinations that are out of beating distance may set up beats between the upper note and the octave harmonic of the other. On this criterion, 3rds and 6ths, especially the minor 6th, are rougher than many combinations that rank as discords, or than some that have never been digested in classical harmony, such as the 7th overtone.

The art of music had not attained to the simplest scheme for dealing with discords before it traversed the acoustic criterion in every direction. It became a language in which sense dictated what should be accepted in sound. The minor 6th, as the inversion of the major 3rd, occurs in many positions of what has come to be the most fixed chord in music, the major triad. On the other hand, a discord beyond beating-distance will have no beats if it is produced in a timbre that has no octave overtones; but if its sense has come to be that of a discord, its timbre will not make it a concord.

The theorists of the 16th century shrewdly regarded the major triad as really a chord of six notes, in the ratios of 1,2,3,4,5,6, which they called the *Sestina*:

Long before this natural phenomenon had been recognized music had organized many other elements into its language, and harmony had become (what it has ever since remained, apart from experiments) counterpoint. This arose, slowly and painfully, out of devices diametrically opposed to it. The organum or diaphonia

of the 10th century amounted to a magadizing in all the perfect concords, *i.e.*, in 4ths or 5ths doubled by octaves, thus:

Its intention was that of a glorified unison and it survives, unheard except as artificial timbre, in the guise of a shrill aura above the notes of the full organ when that instrument is using the most ancient of its registers, the mixture stops. (Some observers have reported the present practice of something like diaphonia in remote parts of Japan.)

The problem of counterpoint was attacked in two ways. First there was a slow evolution through experiments in ornamenting one or more voices of an organum. This gradually took shape as the art of discant, and was slow to move far from the foundation of parallel perfect concords. On the other hand, a violent frontal attack was made by the "motets" of the 13th and 14th centuries, which had no connection with the sublime motet-form of 16th century church music, but consisted in the simultaneous singing of several melodies, independent and perhaps pre-existing; the combination being rough-hewn into a harmony justified by the rule of *marce, ou je t'assomme*. The rough-hewing consisted in contriving that the perfect concords should be conspicuous at the strong accents, on which condition the rest of the harmony could take care of itself. We are apt to misread our documents by forgetting that the note which is now double the length of the longest note in normal use originally deserved its name of "breve." A Hungarian band produces a general harmonic effect more like that of Brahms's Hungarian dances than like any less classical music; but if the details of the Hungarian ornamentation and part-writing were written in breves, semibreves and minims we should find them remarkably like mediaeval counterpoint.

II. PURE POLYPHONY

The first matter of principle that emerged from the chaos was that if the parallel movement of perfect concords was right, everything else was wrong. A few compositions show an evenly-balanced conflict of opposing principles. Our wonderful English rota "Sumer is icumen in" sounds to us like a tuneful six-part double cannon spoilt (or rendered quaint) by numerous consecutive 5ths. Its contemporaries were more likely to have regarded it as a beautiful scheme of perfect concords spoilt or illuminated by dangerous licences. There was no room for prolonged doubt as to where the path of progress and freedom lay. And if the basis of harmony was to be independent melody, then one of the main cares of the composer was to prevent his independent melodies from lapsing into duplications. Fifths and octaves will still form (as they do at the present day) cardinal points in every chord that is dwelt upon; but no two voices can double each other for two consecutive octaves or 5ths without dissolving their integrity in a false resonance.

As to discords the criterion ceased to be acoustical. After centuries of trial and error, musicians accepted 3rds and 6ths as concords; and all discords became equal to one another in mildness when they occurred as unaccented passing-notes proceeding by diatonic conjunct notes between one concord and the next. Polyphony made musical accents far stronger than those of speech; and so the behaviour of accented discords was more restricted. The accented discord must be "prepared" by first appearing as a concord. It then becomes a discord by being held or "suspended" while the other voices move against it; after which it must "resolve" by a step downwards. Upward resolutions are harsh and of complex import, intelligible only in a later system, and so are discords that skip.

Ex. 3 shows passing-notes (marked*) moving up and down between concords:

In Ex. 4 the tied C is a suspension, prepared by having begun as an octave, becoming a discord by colliding as a 4th against a 5th, and resolving by stepping down to a 3rd.

Four three-note chords attained the rank of concords. (Two of them were only inversions of the other two.) First, of course, there was the major triad, the upper three notes (4, 5, 6) of the sestina (Ex. 1). All doublings and differences of octave are negligible in the distribution of a chord so long as they do not bring its middle or upper notes into the bass. All the following examples are concords identical with the sestina and with each other, though the positions that leave two parts low at a distance from the upper parts, or that double the 3rd, are acoustically as rough as many a discord. Positions (d) and (e) could be justified only in circumstances of great polyphonic or instrumental interest.

The essential intervals are those of position (a) and comprise a perfect 5th (G-D), a major 3rd from the bass (G-B) and a minor 3rd above (B-D).

Now in listening to polyphony the mind can appreciate the parts two at a time; and the 16th century theorists avoid reasoning as if the mind could do more. They were probably right as well as cautious; nor is it necessary that the mind should attempt more. For any fault in the aggregate of the richest polyphony must be a fault between two parts. If it concerns more, then it is more than a single fault; and if there are no faults, the ear enjoys the faultless aggregate whether it can distinguish the parts or not. Accordingly the question arises: Will the ear resent an aggregate which corresponds as such to nothing in nature, but which contains no intervals that have not already been accepted in the sestina? In other words, can we treat as a concord a triad which puts the minor 3rd below the major?

The history of harmony not only answers this in the affirmative, but shows that the contrast between this artificial concord and the major triad is essential to the formation of a flexible musical language. Some theorists, fascinated by the ways in which minor harmonies behave like major harmonies reversed, have invented schemes according to which the "roots" of minor chords are their top notes. The way in which minor chords happen in music does not support any theory which makes Ex. 6 anything other than an artificial alteration of Ex. 5, with the same entirely fundamental behaviour of the same bass-note in every relevant musical context. The artificiality of the chord is not arbitrary or conventional; it is of the very nature of art and is far more self-explanatory than most of the phenomena of spoken language.

Both the major and the minor triad are found in "inverted" positions. An inversion is not a reversal, but a position in which

one of the upper notes of the normal chord has become the bass-note. When the 3rd of a triad is in the bass we have the chord of the 6th, thus:

And now arises a phenomenon wholly unintelligible to acoustics and unpredictable by theory. The once perfect concord of the 4th becomes a discord when taken from the bass. Between any higher parts it is a concord; but from the bass it will never do except as a passing-note or a properly prepared and duly resolved suspension. The reason for this is purely contingent. It so happens that practically every context in which an accented 4th occurs from the bass implies a 5th above it, as in Ex. 4. If instead of the 5th you substitute a 6th you will obtain a chord which is theoretically a second inversion of a triad.

But no amount of logic will persuade the ear that this 6th is more than another *appoggiatura* or "leaning-note" demanding as urgently to resolve on the 5th as the 4th demands to resolve on the 3rd. The fact is an accident of far-reaching importance, but as unamenable to grammatical logic as the reason why a modern English poet should not apply the epithet "blooming" to his lady's cheek. Find a context for a 4th from the bass which does not imply the $\frac{5}{3}$ of Ex. 4, and that 4th will cease to be a discord. But it will be some strange and pregnant language, not to be taken in vain; like the cry at the beginning and end of the Allegretto of Beethoven's seventh symphony. And even there the ear is, at the outset, expecting the true bass and remembering it at the end.

The harmonic materials of 16th century polyphony are, then, the major and minor triads, their inversions as chords of $\frac{6}{3}$, and the discords of the 2nd and 7th and (from the bass) the 4th, treated either as suspensions or as passing-notes. The scale in which the flux of polyphony moved through transient discord from concord to concord was the diatonic scale preserved from ancient Greece and handed down directly from the Greco-Roman or Ptolemaic system to the church-music of the middle ages, doubtless with conflation from Jewish sources.

III. MODAL TONALITY

Tonality is the element which groups a succession of musical sounds intelligibly round some centre. With the development of polyphony, tonality becomes as important as the concord-discord system itself; and, indeed, that system could not have existed without tonal guidance at every point. Discord is transition; concord is finality. The task of tonality is to organize various degrees of finality among concords. The first decision made by pure polyphony (but revoked in a later age) was that the minor triad, though it might be a concord, could never be final. A bare 5th or even a bare octave would be more acceptable, as being a potential major triad. The final chord, whether complete or not, requires to be approached by chords in a well-defined relation to it. Two types of full close, or cadence, thus came into existence—the authentic, in which the final chord is preceded by a major chord whose bass is a 4th below or a 5th above the final bass—

and the plagal, in which the penultimate chord is based a 4th

above or a 5th below the final, and is major or minor according to the mode:

The modes were named after those of ancient Greece, wrongly identified in particular; and theory clung to terms derived from non-harmonic notions long after the practice of composers had become inveterately harmonic. An aesthetically-correct account of Palestrina's tonality is much more easily achieved by a description in terms of Beethoven's key-system than by any attempt to refer it to the orthodox modal theory.

According to the finally-prevalent statement of that theory there were ideally 14 modes, two based on each degree of the diatonic scale. Practically the modes based on B were impossible, as the diatonic 5th from B is imperfect. The numbers of these imaginary modes, XI. and XII., were piously retained for them, together with the name of Locrian. The "authentic" modes ran from the "final" or fundamental note to its octave. Each authentic mode was allied to a "plagal" mode, having the same final, but lying a fourth lower. This is an important distinction in purely melodic music and can be clearly recognized in folk-songs. Thus, *The Bluebells of Scotland* is authentic, while *Auld Lang Syne* is, except for an isolated top note, typically plagal. In polyphonic music the difference between an authentic mode and its plagal companion is a vague matter settled by the position of the tenor voice.

The word "modulation" was used in the theory of modal music to denote the formation of full closes on other notes than the final. The 16th century composer developed a perfect sense of key around his cadences, and he knew very well what he was doing when he avoided stimulating that sense elsewhere. He selected his subordinate cadences on no more cogent principle than the avoidance of monotony. He was like a painter whose draughtsmanship is faultless in faces and figures, but who sees no objection to implying a different horizon for each detail in his picture. And harmony has no such relation to external nature as can justify critics in calling modal tonality archaic. Palestrina's tonality is one of the most mature and subtle things in music, and later developments cannot lessen its truth to the nature of art.

Here are the 12 modes which theoretically underlie the tonality of the 16th century. Every composition was written in one of these modes, and its incidental modulations were not regarded as visits to another mode, though that is aesthetically what they really were. The diagram gives the name of the authentic position above each scale, and the plagal name and position below. The white note is the final. The imaginary Locrian modes (with B as final) are omitted.

In practice these modes are not always easy to ascertain. The B natural in Lydian tonality is so difficult to handle that the

great masters almost always flattened it permanently and put the flat as a key-signature, thus producing an Ionian mode transposed, or plain modern F major. (All modes could be thus written a 4th higher; and apart from this, the actual pitch of performance was determined by convenience and was bound by no fixed standard.) The Phrygian mode cannot form an authentic cadence; and its plagal cadence (shown in Ex. 10b) sounds to our ears like a half-close on the dominant of A minor. This is quite final enough for modal harmony; but a very slight impulse may make Palestrina reverse the cadence and so end with a chord of A. This does not make the mode Aeolian, and, though the Aeolian mode looks as if it was the origin of our minor scale, true Aeolian polyphony is of all harmonic styles the most remote from modern music. The Dorian and Phrygian modes are much nearer to our notions of a well-grounded minor key. The Ionian mode is identical with our major key; and Mixolydian tonality is like a major key with either an excessive emphasis on the subdominant or a top-heavy and finally prevalent dominant.

Extraneous sharps constantly come into modal music through the necessity of providing major penultimate chords in authentic cadences, as well as final major 3rds for minor modes. Flats were no less often necessary to correct the tritone 4th between F and B (hence the shape of the flat, and Morley's naming of it as the B clef). The rules governing these accidentals were so well known that singers resented the providing of the signs where the need of such *musica ficta* was self-evident. On the other hand, many of the most mystical harmonies, such as the opening of Palestrina's *Stabat Mater*, were the gifts of creative imagination equally remote from modal theory and modern tonality. Brahms understood modal harmony much better than the critics who blame him for violating the modes of folk-songs by not setting them in a kind of musical Wardour street. If you want to set old tunes without using leading-notes and changes of key you must not harmonize them at all.

IV. ESSENTIAL DISCORDS AND RIGID TONALITY

The strict theory of suspensions and passing-notes was diversified by many idioms which grew up charmingly and illogically. Logic itself admitted harshnesses which the pure taste of Victoria and Palestrina rejected without waiting for the judgment of theorists. For instance, our glorious Tudor masters shared with many other composers outside the Hispano-Roman orbit a keen intellectual pleasure in violent collisions between a major and a minor 3rd over the same bass; *some* 3rd being essential to the harmony and each of the conflicting voices having unanswerable reasons for its own version. But these "false relations," as we now call them, are both archaic and provincial, for all their logic. The overlapping of harmonic ideas produced many results both more pleasant and more fruitful.

Here is an extreme case in which the ordinary rules of *musica ficta* give results which strain the 19th century theorist and compel him to discover "double roots" and other cabalistic secrets.

Ex. 12

The bass singer, knowing his rules of *musica ficta*, would be insulted at such a "donkey's mark" as a flat to the B for the purpose of correcting the inadmissible tritone, comprised between F and B. The treble singer would automatically sharpen his G, under the impression that he was making a close on A; and so the augmented 6th, one of the most complex discords known to Bach and Mozart, did frequently occur in 16th century performances and was not always regarded as a blunder. In Ex. 12 the treble singer would happen to be mistaken in sharpening the G, for it is not really part of a close on to A. The close is on to D, and the middle singer would recognize its leading-note without the aid of "donkey's marks." For our Boeotian age we require a

flat to the B in the bass and sharps for the penultimate Cs in the middle part. If the 16th century composer intended to produce an augmented 6th, he would provide the soprano with a sharp to the G in order to reassure the singer.

But the beginning of the 17th century saw a musical revolution far beyond the scope of any accumulation of licences on the polyphonic basis. The feeble efforts of the first Monodists, Jacopo Peri, Emilio Cavaliere and other pioneers of opera and solo vocal declamation with lute or keyboard accompaniment, had already drawn attention to the value of any and every chord as a thing in itself, apart from its position in a polyphonic flux, when the masterful spirit of Monteverdi gave to the new movement all the power of his intellect and rhetorical instinct. Only a polyphonist can appreciate the real aesthetic values of monody, and Monteverdi was a vigorous, though decadent polyphonist, both before and after he took up monody. But not even his mastery could organize the chaos that overwhelmed the art of music when the limitations of the golden age had been broken down. For one thing, pure polyphony dealt only with unaccompanied voices. When instruments were treated as important elements in serious music the polyphonic hypothesis became inadequate and several new sets of laws had to be found by experiment. A century was no long time for such a task.

Monteverdi's chief innovation is popularly said to be the "invention" of the dominant 7th and of other so-called "essential" discords. An essential discord is merely a discord which through custom has ceased to require preparation; and to attribute its invention to any particular author is like naming the first writer who used a metaphor instead of a full-blown simile. Most, if not all, of the discords that have become essential are based on that part of the key which we call the dominant; for the reason that all harmonic phenomena gravitate towards the full close as inevitably as all verbal statements gravitate round the subject-predicate-copula group. The dominant of a key is the bass of the penultimate chord of an authentic cadence. Opposed to the dominant there is another centre, the subdominant, which supports the penultimate chord of a plagal cadence. A key has, then, three cardinal points: the key-note, or tonic; the dominant, the chief means of orientation in modulations; and the subdominant, whose function we should understand much more readily if we called it the anti-dominant.

The chief and not wholly unconscious aim of the successors of Monteverdi (that is to say, of the composers of the mid-17th century) was to establish the tonic-dominant-subdominant orientation of major and minor keys in a system which could digest essential discords. A modal composition visited other modes than its own whenever it made a cadence other than on its own final; but it did not establish itself in the visited modes; and still less did it go into regions that produced its own mode at a different pitch.

Throughout the 17th century the various streams of music were trickling gently towards a mighty lake, from which all later music takes its origin. Alessandro Scarlatti (q.v.) is now less known to us than his wayward son, Domenico, whose harpsichord music is in a *genre* by itself. But Alessandro, more than any other composer in history, deserves to be considered the founder of a great classical tradition. He is called the founder of the Neapolitan school. And classical tonality is primarily Neapolitan. It recognizes only two modes—the major and the minor. The loss of modal subtleties is more than compensated by the powerful dramatic and architectonic values of clearly-established keys with a capacity for modulation to similar keys in relations of clear harmonic significance.

The following eight bars from the end of the first recitative in Handel's *Messiah*, epitomize several normal features of the system:

Ex. 13

"The voice of one that crieth in the wilderness"

Before discussing this example, we must further explain the system of major and minor keys. Here are the first six degrees of the scale of C major (which, being without sharps and flats, is taken as the standard key) with a triad, or common chord, on each. The notes of these triads are all within the key. The functional names of each degree are given below, and the number above in Roman figures. Large figures indicate major chords and small figures minor.

Ex. 14

I. ii. iii. IV. V. vi.

Tonic Supertonic Mediant Subdominant Dominant Submediant

The 7th degree, or leading-note, bears no common chord within the key, for its triad has an imperfect 5th. The submediant is so called because the subdominant is not conceived as the note below the dominant, but as an anti-dominant, a fifth below the tonic, so that there is a submediant as a 3rd between it and the tonic, just as there is a mediant as a 3rd between the tonic and dominant.

Another most important gain of the new tonality as against the modal system is that the minor mode can now so firmly support its tonic by its other chords that a minor tonic chord becomes convincing as a final. The contrast between major and minor keys acquires a high emotional value. We must clearly understand that the minor mode, like the minor triad, is identified with the major mode on the same tonic. The so-called "relative major" is one of five equally direct relations to a minor tonic and the "relative minor" is one of five to a major tonic. The minor mode of C is not (as the Tonic Sol-fa system will have it) A minor, but C minor.

In the minor mode a strict confinement to cardinal harmonies produces a melodically awkward augmented 2nd between the flat 6th and the necessarily sharp leading-note. Accordingly the external form of the scale varies and the variations have harmonic results. Ex. 15 shows the so-called harmonic and melodic minor scales.

Ex. 15

Harmonic Melodic

The melodic form avoids the augmented 2nd by sharpening the 6th in ascent and flattening both 6th and 7th in descent.

V. CLASSICAL KEY-RELATIONSHIPS

A fundamental proposition in the aesthetics of tonality is that key-relationship subsists between two tonics only and has nothing to do with the intervention of a third tonic. Observe the word tonic; the proposition commits us to no specified mode on either side of the relation.

Direct relationship exists between two keys when the tonic chord of one is among the common chords of the other. If our first key is major, we simply identify its related keys with its common-chords other than its tonic; thus Ex. 14 shows that C major is directly related to five keys, D minor the supertonic, E minor the mediant, F major the subdominant, G major the dominant, and A minor the submediant.

The relatives of a minor tonic have to be discovered by a converse process, for the minor scale is so unstable that the evidence of its common chords is conflicting and misleading. For instance, the dominant chord of a minor key is major. But you will receive a shock if you try answering the subject of Bach's G minor Fugue, Bk. I., No. 16, of *Das Wohltemperirte Klavier* in D major instead of D minor! Evidently the only directly related dominant key to a minor tonic is also minor. This being so, the subdominant must be minor also, for it is the converse of the dominant, the key to which the tonic is dominant. In order to reach it the tonic chord must become major; a pathetic effect

constantly to be found near the end of classical slow movements in minor keys.

The other relations of a minor tonic are converse to the relations of a major tonic. Thus, if D minor be the supertonic of C major, we must find a name for the relation of C major to D minor. We run up the scale of D minor and find that C is its flat 7th. Similarly, if E minor is the mediant of C major, then C major is the flat 6th or submediant of E minor; and, lastly, if A minor is the submediant or relative minor of C major, then C major is the mediant or relative major of A minor. And so the relations of a minor tonic may be obtained by reading Ex. 14 backwards, with A minor as the key of reference. Transposing Ex. 14 so that vi. becomes C minor, we obtain the following five relations: B flat major the flat 7th, A flat major the submediant, G minor the dominant, F minor the subdominant, E flat the mediant (or relative major).

It is now easy to describe the drift of the Handelian chords of Ex. 13. The key-signature is that of E major, a key that differs only in pitch and in minute instrumental technicalities from all other major keys. (Ideas as to the characters of keys in themselves are entirely subjective, and no agreement is to be expected about them.) The first chord is a common-chord of B major, the dominant of E. In its present context it represents not only the dominant chord, but the dominant key, for it happens to be the close of a passage in B major. The next chord is still a dominant chord, but effects a return to E, being the last inversion of the dominant 7th thereof. The 7th is in the bass, and duly resolves on G sharp in the next chord, a first inversion of E (bar 3). Handel would have had less scruple than many later writers in letting the bass skip down to E, so long as the G sharp was somewhere in the chord, but here he is making his bass regularly descend the scale. The next step, F sharp, supports another dominant chord, that of C sharp minor (vi. from our tonic) in its last inversion, like that in bar 2. It also resolves in bar 5. Bar 6 passes to the subdominant (A major) and bar 7 establishes that key in a manner to remove all doubt by striking its subdominant chord, which is wholly outside the range of E major. The natural result is the full close in A major in bar 8. Such is the normal way of using key-relations in the essentially Neapolitan art of Handel; and all the intensity of Bach's thought adds nothing to its essential elements. When Bach modulates more widely his purpose is, like that of Handel in "Thy rebuke hath broken his heart," not to explain, but to astound.

Another great change had to enlarge the art of music before key-relations could attain their full meaning; but this time the change was accomplished without a period of chaos. It was like Kant's "Copernican revolution" in philosophy; and its more general aspects are discussed in the articles INSTRUMENTATION, MUSIC, OPERA and SONATA FORMS.

Its first effect on harmony was shown in a drastic simplification of style; for music had now become dramatic, and there was no musical resource of more cardinal dramatic importance than changes of key. Consequently the baldest facts of key-relation became dramatically significant, out of all proportion to their direct intellectual import. A musical historian can make no graver blunder than to mistake Mozart's and Haydn's harmonic simplicity for an intellectual simplicity. To prolong a preparatory harping on the dominant of a new key is equivalent to working up the entry of an important person in a drama.

A hundred years before the problem which Alessandro Scarlatti solved in his youth might be described as that of finding the dominant. The simple-seeming Mozart is, as often as not, mocking us with the riddle "When is a dominant not a dominant?" Musical perspective has gained another new depth in its command of planes. A modulation may establish a new key firmly enough for an incident in the course of a melody, but not nearly firmly enough for a new stage in the whole scheme. Conversely, a passage which at first sounded like vehement emphasis on the local dominant may, long afterwards, when the dominant key has been firmly established, be given note for note at the same pitch with a triumphantly tonic effect. And the dimensions over which Mozart's tonality maintains its coherence are enormous;

sometimes almost on Beethoven's largest scale.

Music, which in Palestrina's age was "a linked sweetness long-drawn out," with the links extending only from one accent to the next, had by the beginning of the 18th century trained the mind to measure harmonic relations over melodic periods of eight or more bars; and the mighty polyphony of Bach and Handel broke down the melodic regularity, but did not greatly enlarge the range over which the listener must depend on his memory. These masters can visit the same key several times in a composition without inciting the listener to notice the fact either as a purpose or as a tautology. But Mozart, Haydn and Beethoven build confidently on a knowledge of the exact effect that a modulation in one passage will have on a passage five or even ten minutes later. Beethoven's enormous architectural and dramatic power enabled him to discover and command the whole range of key-relationship theoretically possible within any definite meaning of the term. There is no limit to the possible range of modulation, as Bach took pains to show; but "the unity of the chromatic scale" is a feeble dogma on which to base the notion that Beethoven ought to have treated all keys as equally related, instead of drawing the line where he did. Great artists discover facts and resources, not licences and vagaries.

Haydn, Mozart, Beethoven, Schubert, Brahms and Wagner all agree in one simple and cogent method of extending the direct or natural series of key-relations. They merely changed the modes of either or both numbers of a directly related pair. Certain reservations were necessary; the supertonic of a major key which is quite happy as a minor neighbour completely fails to sound like a major key in its own right and behaves merely like "dominant preparation" for the ordinary dominant. An analyst who imputes the key of A major to bars 19-24 of the first movement of Beethoven's G major sonata op. 14, No. 2, *when he hears them in their context*, should not attempt to discuss key-relationship until he can discriminate between a passage *on* the dominant and a passage *in* the dominant.

What is true of one key-relationship will be true of its converse: the key of the flat 7th refuses to assert itself as a real key in relation to a major tonic. A dozen accessory chords in D major would not make the 7th bar of Ex. 13 amount to more than the subdominant chord in A major until they included a chord of G. The testimony of such openings as those of Beethoven's sonatas opp. 31 (No. 1) and 53 is emphatic.

In the rare cases where such keys do not thus explain themselves away, their effect is startling. (Ineptitudes may be neglected.) The passage that follows the return of the main theme in the first movement of Beethoven's Eroica symphony is one of the supreme dramatic strokes in music. The hard-won tonic of E flat gives way first to F major and then to the opposite extreme, a 3rd lower, D flat. Another third down brings us safely to our own dominant chord.

One other type of key-relation is derived from a special form of the minor scale, in which the lower tetrachord is made to correspond with the upper—

Ex. 16

The first inversion of its flat supertonic chord is known as the Neapolitan 6th; and the Neapolitan key-relations are the flat supertonic major, equally related (as the E natural in Ex. 16 shows) to a major and a minor tonic, and the converse relation of the sharp 7th. A minor tonic has no direct converse relation, for the Neapolitan chord is major. But, as Schubert shows at the end of the first movement of his D minor quartet and in the slow movement of his string quintet in C, an indirect relation may be established by making the Neapolitan chord minor.

We must beware of imputing relationship to keys separated by discursive modulation unless we have strong collateral evidence from the key-functions of a musical design. Tonality and form are inseparable; and great composers do not even expect the tonic to be recognized after long wanderings, without some such

conclusive evidence as the return of the opening theme.

Here are two tables, indicating by Roman figures the whole scheme of key-relationships, first from a major tonic, secondly from a minor tonic. Flats indicate degrees flattened in comparison with those of the major scale of reference; and in Table B sharps are used to distinguish cases where the key is a semitone above the corresponding degree of a minor scale. Thus, if C be the tonic, E major will be represented by III in Table A, and by III \sharp in Table B. In either table the figure iii \flat would, reckoned from C, be E flat minor.

TABLES OF KEY-RELATIONSHIPS

A. From Major Tonic.

	I	Direct Relationships	ii	iii	IV	V	vi
		Indirect through both i and the second key			iv	V	
Indirect through i							
III \flat VI \flat		Indirect through the second key		III			VI
Doubly indirect through the former indirect keys iii \flat vi \flat							
Neapolitan, direct		II \flat				VII and vii	
Neapolitan, indirect		ii \flat					
Unconnected		IV \sharp and iv \sharp = V \flat and v \flat					and all enharmonic synonyms of other keys
Ambiguous			II				VII \flat and vii \flat

B. From Minor Tonic

	i	Direct Relationships	III \flat	iv	v	VI \flat	VII \flat
		Indirect through both I and the second key		IV	V		
Indirect through i							
iii \sharp vi \sharp		Indirect through the second key	ii \flat				vi \flat
Doubly indirect through the former indirect keys III \sharp VI \sharp							
Neapolitan, direct		II \flat					
Neapolitan, indirect		ii \flat					VII \sharp and vii \sharp
Unconnected		IV \sharp and iv \sharp = V \flat and v \flat					and all enharmonic synonyms of other keys
Ambiguous	ii	II	vi \flat				

The characters of key-relationships are solid facts, and they probably have some bearing on the various subjective ideas which many music-lovers entertain as to the character of keys in themselves; for nobody can name a key without being aware of its distance from C major. Be this as it may, it is an undisputed fact that modulations in a dominant direction have an effect of action, while modulations towards the subdominant have an effect of retirement. With a major tonic the three remaining directly-related keys are minor, a contrast which outweighs their other distinctive characters. To move from a major tonic to the relations of its tonic minor, such as III \flat and VI \flat , is to pass into deep and warm shadow. Such modulations form characteris-

tic purple patches in the course of Mozart's "second subjects."

Changes from a major tonic to the major mode of its mediant or submediant are extremely bright. Haydn, who explored all the range of tonality in contrasts between whole movements, or between a minuet and its trio, is very fond of using them in this way in his later works. Beethoven incorporates them in the most highly-organized functions of his sonata-movements. The Neapolitan relations appearing once as a paradox in Haydn's last pianoforte sonata, are completely rationalized by Beethoven, Schubert and Brahms. The flat supertonic casts a deep warm shadow over the tonal scheme, and becomes sheer blackness in the rare cases where it is changed to minor. Conversely, the move a semitone downwards from the tonic (to VII \sharp or vii \sharp) is a move into mysterious brightness. Other extreme depths are sounded in the double changes from a major tonic to iii \flat or vi \flat ; which (with convenient change of notation) may be found in Beethoven's sonata op. 106 and Schubert's last pianoforte sonata. The converse relations III \sharp and VI \sharp from a minor tonic are very bright; the only really bright contrasts that the minor key-relations possess. Beethoven's C minor concerto shows III \sharp , and his F minor quartet shows VI \sharp .

VI. THOROUGH-BASS

The great classical tradition cares little for the study of chords as things in themselves; and the art of harmony perishes under a discipline that separates its details from counterpoint and its larger issues from form. An excellent means of mastering a good harmonic vocabulary is to practise the filling-out of classical figured basses at the keyboard; in other words, to exercise the function of the continuo-player who, from the time of Monteverdi to that of Beethoven's organ-teachers, used to supply accompaniments from a bass with figures indicating the gist of the chords required. Fluency in such a practice does not of itself confer the ability to produce original harmony, but it means that music can be read with understanding. It is an empiric craft. But it had the misfortune to become a science, when, early in the 18th century, Rameau discovered the theory of the fundamental bass. This is an imaginary bass (best when most imaginary) that gives "roots" to all the essential chords of the music above it. The conception is true only of the most obvious harmonic facts; beyond them it is as vain as the attempt to ascertain your neighbour's dinner from a spectrograph of the smoke from his chimney. The augmented 6th which arose so innocently in Ex. 12 requires a double root. The first chord of Beethoven's sonata in E flat, Op. 31 No. 3, is an "eleventh" with its root on the dominant in flat defiance that the dominant is the most inconceivable bass-note in the whole passage until it arrives as a climax in the sixth bar. But musical fundamentalists refuse to look six bars ahead.

Philipp Emanuel Bach, in conversation with Dr. Burney (*The Present State of Music in Germany, etc.*), said that Rameau's theory was "childish, for it reduces all music to full closes." This is perfectly true, and the theory did no harm to 18th century French music, which eschewed long sentences and seldom strayed far from the regions of the full close. But in England Rameau's doctrine raged unchecked by taste or common sense, and culminated in Dr. Day's famous application of homoeopathy to the art of music. This would have mattered less if Dr. Day had not gained the ear of the greatest English academic musicians of Mid-Victorian times. As Sir Charles Stanford aptly says (*Musical Composition*), Day's theory "irrigated a wide area of low-lying ground, and we are still suffering from the effects of its miasma." The remedy lies in cultivating vivid impressions of the actual relations between counterpoint and harmony in detail, between tonality and form in general, and between key-relations and chromatic chords. To this end, thorough-bass should be cultivated not on paper but at the keyboard, with passages (graded according to difficulty) from the continuos of Bach's cantatas and Mozart's church music.

VII. TEMPERAMENT AND JUST INTONATION

Even in pure 16th century polyphony the ideal diatonic scale implies distinctions of intonation beyond the capacity of any

mechanical instrument with a limited number of notes. In the Ionian mode or major scale of C the interval C-D is not the same kind of whole tone as the interval D-E, but differs as 8:9 from 9:10.

The normal position for the supertonic is a "major tone" (8:9) above the tonic; but even so common a discord as the dominant 7th will set up a conflict, the dominant requiring its 5th to be as 9:8 above the tonic, while the 7th will want to make a true minor 3rd from a supertonic in the position of 10:9. Such conflicts are about very minute distinctions, but every discord produces them if it is dwelt upon. Nevertheless, the 12 notes that human hands can negotiate within a span-stretched octave suffice to express the most chromatic harmony with less average inaccuracy than is cheerfully permitted in human singing and violin playing. Singers and violinists can and do constantly achieve a purer intonation than that of keyed instruments; but the only aesthetic issue between free voices and tempered instruments is the difference between a human intonation liable to human error and an instrumental intonation with an inherent systematic error. The human error is often not only accidentally, but deliberately in excess of the systematic error, for the slightest *vibrato* is larger than the quantities involved.

The subject of just intonation is fatally fascinating to people whose mathematical insight has not attained to the notion of approximation. In art, as in mathematics, accuracy lies in estimating the relevant degree of approximation rather than in unrolling interminable decimals. Music is no more to be heard through Helmholtz resonators than pictures are to be enjoyed through microscopes. The true musical ear will recognize the real meaning of harmonies though the practical intonation confounds them with homonyms. Bach introduced no new musical thought when he arranged *Das Wohltemperirte Klavier* to stimulate the adoption of equal temperament by providing music in every major and minor key for which the keyboard had notes. Systems of unequal temperament tuned the commoner keys as well as possible, in the hope that remoter keys would never be visited. Bach decided that it was better to have all keys equally out of tune than to have some keys intolerable. The miraculous modulations of his *Chromatic Fantasia* deliberately emphasize all the chords that were "wolves" in unequal temperament, and thus Bach devoted his highest efforts of imagination to a humble practical purpose. But Marenzio had modulated as far in madrigals written in the purest golden-age polyphony. No true harmonic ideas are based on equal temperament, any more than a true geometry is based on exclusively rational quantities.

VIII. METHODS OF MODULATION

The commonest way of establishing a change of key is, as we have seen, to emphasize the dominant chord of the new key until only the new tonic can be expected. This we will call dominant modulation; leaving out of consideration how the new dominant is reached. (It was probably surrounded by its own dominant-of-dominant which could be reached from various other directions.)

A more interesting type of modulation begins with Beethoven, arising out of hints given by Haydn and Mozart. It may be called functional modulation, and consists in placing indirectly-related keys into positions which make their exact relation appear vividly. If the first chord of the second key is a dominant, the relation will still appear in high relief; but any further decoration of that dominant will reduce the result to an ordinary modulation. (Compare bars 22-23 of the first movement of Beethoven's *Waldstein* sonata with the drastic process of bars 37-38 in the first movement of op. 106.)

Functional modulation might well be called "natural" if that term had not been commonly assigned to modulation within the five directly-related keys, irrespective of method.

Mere juxtaposition of tonics will suffice for the purposes of a functional modulation. If Beethoven had wished to explain the presence of F sharp minor (vi \sharp) in the scheme of op. 106, the natural (or functional) process would consist of the following four chords:

Ex. 17

Closely akin to this method is Beethoven's dramatic way of reducing a chord to a single note, and then building up therefrom a quite remote chord. (See opp. 90 and 81a.)

All such devices show the listener what is really happening. The object of *enharmonic* modulation is frankly to mystify. It is popularly supposed to belong specially to tempered scales; but it really presupposes just intonation. All discords, as we have seen, set up a conflict in their intonation; and an enharmonic modulation is merely a conflict so coarse-grained that it appears in the notation by some such mark as a change from G \sharp to A \flat . An ill-motivated enharmonic modulation is like a bad pun; a great enharmonic modulation is a sublime mystery. Here is the commonest pivot of enharmonic changes, the diminished 7th, with its four vastly different resolutions:

Of course, these are really four different chords. If the true theory of just intonation demanded that the minor scale should be rigid, a chord of the diminished 7th would be much harsher than the tempered scale makes it. But what really happens in just intonation is that two notes of the minor scale become so unstable in the stress of discord that it becomes a small matter to shift the strains to whatever notes you please. Even with a limited keyboard the ear imagines a change of intonation when the unexpected resolution appears. This is why chromatic intervals are difficult to sing; the singer loses confidence when he has to aim at a note which will not stand still.

Not every change of notation represents a genuine enharmonic modulation. Modulate diatonically from A to F: and transpose your modulation down a semitone. You will start in A flat, but if you have much to say in the second key you will probably prefer to write it as E, instead of F flat. Sad nonsense has been written by many commentators on the most ordinary harmonies disguised by convenience of notation.

Nevertheless, a merely notational change may eventually have an enharmonic result, for it may be part of an enharmonic circle. If the harmonic world is round, why should just intonation be plane? Adjustments infinitely smaller than those of temperament will suffice to make the ends of an enharmonic circle meet in the course of a long composition. The first movement of Brahms's F major symphony, played with its repeat, goes four times round an enharmonic circle of major 3rds (F, D \flat , B \flat = A, F). Every time the key written as F returns it identifies itself by the opening theme. If the pitch rose to G \flat we would scarcely notice the fact after the intervening passages, and when the pitch had risen noticeably we should complain. Temperament keeps the pitch; but just intonation could do so by an even distribution of infinitely smaller adjustments.

It now becomes clear why keys a tritone 4th apart cannot become related. That interval (which modal musicians identified with the devil) constitutes the kink in musical space. It sets up an enharmonic short-circuit; a modulation from C to F sharp is exactly the same as one from G flat back to C; and whichever key you start from, the other will sound like the dominant of a Neapolitan key instead of asserting its own rights. No sensible person forbids the modulation; its effect may be excellent, but it is not the effect of a key-relation.

IX. WAGNERIAN HARMONY

Wagner's sense of key is exactly the same as Beethoven's; but it has hours in which to exercise itself, whereas Beethoven's

designs seldom stretch without break over 15 minutes, and always show their purport within five. But take, for example, the conflict between two major keys a tone apart. The jealous Fricka *did* hope (in F major) that the domestic comforts of Walhalla would induce Wotan to settle down. Wotan, gently taking up her theme in E flat, dashes her hopes by this modulation more effectively than by any use of his artillery of tubas and trombones.

But the most distinctive feature of Wagner's harmony is his use of long auxiliary notes in such a way as to suggest immensely remote keys, which vanish with the resolution. (Chopin anticipates Wagner in what Sir Henry Hadow finely describes as "chromatic iridescence.")

Here is the evolution of the wonderful opening of *Tristan und Isolde*:

Ex. 19.—Three concords (tonic, first inversion of subdominant, and dominant of A minor, a possible 16th-century cadence in the Phrygian mode).

Ex. 20.—The same chords varied by a suspension (*).

Ex. 21.—Ditto, with the further addition of a double suspension (*) and two passing notes (†).

Ex. 22.—Ditto, with a chromatic alteration of the second chord (*) and an "essential" discord (dominant 7th) at (†).

Ex. 23.—Ditto, with chromatic passing notes (**) and appoggiaturas (††).

Ex. 24.—The last two chords of Ex. 16 attacked unexpectedly, the first appoggiatura (*) prolonged till it seems to make a strange foreign chord before it resolves on the short note at †, while the second appoggiatura (†) is chromatic.

Ex. 25.—The same enharmonically transformed so as to become a variation of the "dominant ninth" of C minor. The G \sharp at * is really A \flat , and † is no longer a note of resolution, but a chromatic passing-note.

X. POST-WAGNERIAN HARMONY

The line of evolution traced thus far has, evidently, no *a priori* limits, though it has principles. Any new system is destined either to starve for lack of nourishment from the main sources of music or become absorbed in them. Systems derived from equal temperament are crude fallacies. The whole-tone scale which readily arises on the pianoforte, e.g., C, D, E, F, \sharp (= G \flat , A \flat , B \flat , C), amused Debussy during a few dozen songs and short pieces, and played a much less predominant part in his *Pelléas et Mélisande* than is generally supposed. It is really no more a whole-tone scale than the diminished 7th is a major 6th bounding a series of minor 3rds. Sir Walford Davies points out that this scale is a six-note chord projected into a single octave and capable, like the diminished 7th, of an enharmonic turn to each of its notes. Here is one of several possible ways of showing the six resolutions of this scale:

Ex. 26

Enthusiasts for new systems are naturally infuriated when the systems thus fade into the light of common or Wagnerian day. Nevertheless, the pleasure given by every effort at revolutionary harmony results from the fact that the new chords enter our consciousness with the meaning they would bear in a classical scheme. Not only Wagner, but Bach and Palestrina lurk behind every new harmonic sensation and cannot long be prevented from making sense of it. After sense has been made, the fundamental theorists will return and prove to us that many quite commonplace chromatic progressions contain the triskaidekahyperhendaenneaheptachord of Ex. 26 with the omission of not more than four of its notes.

Other new theories are not less quickly worn out, even when invented by gifted composers. Scriabin, each of whose last five sonatas is built round its own new chord, complained shortly before his untimely death that he had, after all, not succeeded in getting away from a sophisticated dominant 7th. This complaint recalls Philipp Emanuel Bach's criticism of Rameau's theory, and its cause lies deep in the very nature of articulate thought. If you wish to compose freely, do not fix your mind on new harmonic propositions. Language is not extended by declining to use what is known of it.

Arnold Schönberg's harmonic theory is often masterly in its analysis of classical music; but it is extremely disappointing in its constructive aspect. Not only does Schönberg think the absurd old theory of "added 3rds" worth refuting, but he invents a new theory of added 4ths which has even less foundation. The theory of "added 3rds" was no more scientific than a classification of birds by the colour of their feathers. But birds do have feathers of various colours, and classical music does build up chords by sequences of thirds. Schönberg's theory rests on no observation at all, for the piling up of 4ths has no origin in classical harmony and only a quickly exhausted melodic value. However, it can be carried right round the tempered scale in 12 steps and *ad infinitum*

in just intonation. To find the composer of the *Gurrelieder* fathering such theories is as disconcerting as to discover Einstein telling fortunes in Bond street.

THEORETIC POSSIBILITIES OF THE FUTURE

Harmony has not yet found a place for so simple a natural phenomenon as the 7th note of the harmonic series. Here are the first 16 notes from bass C as the fundamental. Many a "clang" contains them all in appreciable strength, yet no fewer than three (besides the octave of No. 7) are outside our system, Nos. 7 and 13 being much flatter than the notes here written, and No. 11 much sharper.

Ex. 27

Again, though resultant tones are audible enough to save organ-builders from the expense of 32 ft. pipes by means of devices which reinforce the resultant tone and obliterate its generators, they have played no acknowledged part in musical aesthetics. A theory which builds upon them must abandon the hypothesis that all harmony grows upwards from the bass. Abandon it by all means if your musical intuitions inspire you with ideas based on resultant tones—by which, however, you must mean something different from harmony whose ideal bass lies in its resultant tones—for that will merely be another notion of fundamental bass, differing from Rameau's, but again forcing you to regard harmony as rising from the bass. And, after all, the hypothesis is not a theory, but an experience. The language of music has, in fact, taken shape without guidance from resultant tones; just as the art of painting has, until recent epochs, made no conscious use of complementary colours, except by instinctively avoiding ugly or unintelligible effects.

Schönberg rightly says that *das Einfall*, the inspiration that comes without theorizing, is the sole criterion of musical truth; and perhaps some composers may have *Einfälle* so convincing in their use of Nos. 7, 11 and 13, as to compel us to build new instruments for them. And so with the use of a resultant-tone or inverted harmonic system. The string-quartets of Haba have not as yet made quarter-tones sound convincingly unlike faulty intonation. We must not blame our ears, which often appreciate much smaller measurements. The just intonation of a Wagner opera would comprise some thousand notes to the octave. The question is not how many notes we use in the long run, but how small a direct measurement is of interest to us. The carpenter deals faithfully with the incommensurable when he so much as fits a cross-bar to a square gate.

Many other modern harmonic tendencies are essentially matters of instrumentation. If, abandoning the polyphonic hypothesis, we use chords, simple or complex, as mere unanalysed tone-colours, we can start a new polyphony with moving chords instead

Ex 28

Triplanar harmony and doubling of melodies in whole chords

R. VAUGHAN WILLIAMS. *Pastoral Symphony*.

of moving single parts. Our problem, then, will be to keep the planes of tone distinct. Organ-mixtures, if not properly drowned by the fundamental tones, would shock the boldest multi-planar harmonist by the mess they would make of classical harmony.

Extremes meet, and we are recovering a sense of the values of unharmonized melody: not melody which wants to be harmonized, nor melody which achieves harmonic sense by draughtmanship, but the austere achievement, far more difficult than any "atonality," of a melody that neither needs nor implies harmony. And so we return to nature.

(D. F. T.)

HARMOTOME, a mineral of the zeolite group, consisting of hydrous barium and aluminium silicate, $\text{H}_2\text{BaAl}_2(\text{SiO}_3)_4 \cdot 5\text{H}_2\text{O}$. Usually a small amount of potassium is present replacing part of the barium. The system of crystallization is monoclinic; only complex twinned crystals are known. A common and characteristic form of twinned crystal consists of four intercrossing individuals twinned together according to two twin-laws; the compound group resembles a tetragonal crystal with prism and pyramid, but may be distinguished from this by the grooves along the edges of the pseudo-prism. Crystals are usually white and translucent, with a vitreous lustre. The hardness is $4\frac{1}{2}$, and the specific gravity 2.5.

Like other zeolites, harmotome occurs with calcite in the amygdaloidal cavities of volcanic rocks, for example, in the dolerites of Dumbartonshire, and as fine crystals in the agate-lined cavities in the melaphyre of Oberstein in Germany. It also occurs in gneiss, and sometimes in metalliferous veins.

HARMS, KLAUS (1778–1855), German divine, was born at Fahrstedt, Holstein, on May 25, 1778. He became a fervent Evangelical preacher, first at Lunden (1806), and then at Kiel (1816). His best book was *Pastoraltheologie* (1830–34, 3 vols.; new ed. 1891–93, 2 vols.). He died on Feb. 1, 1855.

See his autobiography, *Harms' Lebensbeschreibung* (1851, new ed., 1888).

HARNACK, ADOLF VON (1851–1930), German theologian, was born on May 7, 1851 at Dorpat, Estonia, where his father, Theodosius Harnack (1817–99), author of a well-known work—*Luther's Theologie* (1862–68; new ed., 1926)—was professor of pastoral theology. Adolf studied at Dorpat and at Leipzig, where he became privatdozent (1874) and professor extraordinarius (1876). He occupied chairs at Giessen (1879), Marburg (1886–89) and Berlin (1889–1924). He was also director of the Prussian National Library (1905–21) and president of the Evangelical Congress (1902–12). He was ennobled in 1914.

Harnack's chief work, *Lehrbuch der Dogmengeschichte* (4 vols., 1886–90; 6th ed. 1922, in *Grundriss der theol. Wiss.*; Eng. trans. 7 vols., 1894–99), strongly affected Protestant thought both in Germany and in other countries. He traces the rise of dogma, by which he understands the authoritative doctrinal system of the 4th century, and its development down to the Reformation. His general thesis is that in its origins the Christian faith was so strongly influenced by the contemporary developments of Greek thought that much that was inessential to Christianity found its way into the beliefs and practice of the Church. Therefore, Protestant Christians were free, even bound, to criticize dogma (in the sense understood by Harnack). In fact, he tried to reconcile Lutheran doctrine with modern tendencies of thought, finding his justification by reference to early church history, of which he was an acknowledged master. He was violently attacked for unorthodoxy, and his appointment to Berlin in 1888 was opposed by conservative Lutheran authorities. There he was drawn into controversy over the Apostles' Creed, which, he maintained, in his *Das Apostolische Glaubensbekenntnis* (1892), contained both too much and too little to be a satisfactory test for candidates for ordination. At Berlin he held a seminar, in which he trained a body of students to distrust speculative theology, and to demand absolute freedom and an open mind in the study of Church history and of the Bible. He died at Heidelberg on June 10, 1930.

Harnack's other works include: *Das Moncktum, seine Ideale und seine Geschichte* (1881, 10th ed., 1921); *Geschichte der altchristlichen Literatur bis Eusebius* (3 vols. 1893–1904), incomplete; *Das Wesen des Christentums* (1900 and many later ed.;

Eng. trans. *What is Christianity*, 1901); *Die Mission und Ausbreitung des Christentums in den ersten drei Jahrhunderten* (1902; 4th ed. 1914; Eng. trans. 2 vols., 1904–05); a collection of papers, *Beiträge zur Einleitung in das Neue Testament* (4 parts 1906–11; Eng. trans. of some of these: *Luke the Physician*, 1907, and others); *Entstehung und Entwicklung der Kirchenverfassung und des Kirchenrechts in den drei ersten Jahrhunderten* (1910); *Marcion* (Leipzig, 1921); *Briefsammlung des Apostel Paulus* (1926). With O. L. von Gebhardt and T. Zahn he published *Patrum apostolicorum opera* (1876); with Gebhardt and K. Schmidt, the periodical, *Texte und Untersuchungen z. Gesch. der altchristl. Lit.* (Giessen, 1882, seq.).

A complete bibliography is given in a special Harnack number of *Naturensenschaft* (vol. xix., 1926). See his own *Erforschtes und Erlebtes* (1922).

HARNESS, gear, tackle, equipment in general (from O. Fr. *harneis* or *harnois*); early applied to the body armour of a soldier, and the trappings of the horse; now the general term for the gear of an animal used for draft purposes, traces, collar, bridle, girth, breeching, etc. (See **SADDLERY** AND **HARNESS**.)

HARO, CLAMEUR DE, the ancient Norman custom of "crying for justice," still surviving in the Channel islands. The wronged party must on his knees and before witnesses cry: "Haro! Haro! Haro! à l'aide, mon prince, on me fait tort." This appeal has to be respected, and the alleged trespass or tort must cease till the matter has been thrashed out in the courts. The "cry" thus acts as an interim injunction, and no inhabitant of the Channel islands would think of resisting it. This method of appeal is said to be identical with the "Legatro of the Bavarians and the Thuringians," and the first mention of it in France is to be found in the "Grand coutumier de Normandie." A similar custom, only observed in criminal charges, was recognized by the Saxon laws under the name of "Clamor Violentiae." Thus there is reason to think that William the Conqueror on his arrival in England found the "cry" fully established as far as criminal matters were concerned. Later the "cry" was made applicable to civil wrongs; and, when the administration of justice became systematized, disappeared altogether in criminal cases. It was long retained in north-western France in cases of disputed possession, and was not actually repealed until the close of the 18th century. (See **HUE** AND **CRY**.)

HARO, LUIS DE (1599–1661), Spanish diplomat, son of the marquis of Caspio and nephew of the duke of Olivares, whom he succeeded as prime minister in 1643. The disastrous war with France and her allies continued until 1659, when Haro concluded with Mazarin the treaty of the Pyrenees. The terms were hard, and Haro was diplomatically no match for Mazarin, but he brought much-needed peace to Spain, and was rewarded by the elevation of the marquessate of Caspio into a dukedom and the title of "prince of the peace." He died at Madrid on Nov. 26, 1661.

HAROLD I. (d. 1040), surnamed Harefoot, the illegitimate son of Canute, king of England, and Aelfgifu of Northampton. On the death of his father in 1035, he claimed the crown of England in opposition to Canute's legitimate son, Hardicanute. His claims were supported by Leofric, earl of Mercia, and the north. Eventually Harold was temporarily elected regent, pending a final settlement on Hardicanute's return from Denmark. In 1037 he was definitely elected king, and banished Emma mother of Hardicanute. The only events of his reign are ineffectual inroads of the Welsh and Scots. Harold died at Oxford on March 10, 1040.

HAROLD II. (1022?–1066), king of the English, the second son of Earl Godwine, was born about 1022. While still very young (before 1045) he was appointed, through his father's influence with Edward the Confessor, to the earldom of the East Angles. He shared his father's outlawry and banishment in 1051, but while Godwine went to Flanders, Harold with his brother Leofwine took refuge in Ireland. In 1052 the uneasiness felt at the visit to England of William, Duke of Normandy, who was known to covet the English throne, caused a reaction in favour of Godwine, who returned to England with his sons, under arms. The witan finally decreed that their lands should be restored. Harold

therefore received his earldom of the East Angles, and on his father's death in 1053 succeeded him in the greater earldom of the West Saxons, Sweyn having died while on a pilgrimage to Jerusalem. Harold was now the chief man in the kingdom, and the latter part of Edward's reign was virtually the reign of Harold. On the death (1055) of Siward, earl of Northumbria, Edward, at the instigation of Harold, appointed his brother Tostig earl of Northumbria; Earl Aelfgar looked upon this appointment as a menace to the Mercian house, and his opposition led Harold to procure his outlawry by the witan. Aelfgar then joined Gruffydd, Prince of North Wales in an attack on Hereford, as the result of which Aelfgar regained his position as earl of East Anglia. In 1057, with the exception of Mercia, Harold and his brothers held all the earldoms throughout England. Aelfgar, in order to secure a useful ally, married his daughter Ealdgyth to Gruffydd. Aelfgar died in 1062, and was succeeded by his son Edwin. In spite of the alliance between the Mercians and the Welsh, Harold and Tostig raided Wales in 1063, and forced Gruffydd, who was eventually killed by his own men, to flee. In 1063 Harold was shipwrecked on the French coast, and captured by the Normans, who only released him on his oath on sacred relics (though at the time he was unaware of their nature) to support William in any claim for the English throne. Probably on his return to England, though the date is uncertain, Harold married Ealdgyth (Edith), sister of Edwin, and widow of Gruffydd, thus conciliating the powerful earl of Mercia. His mistress, Eadgyth of the Swan-neck, the mother of his children, was still living. In 1065 the Northumbrians revolted against Tostig's rule, choosing Morkere, brother of Edwin of Mercia, in his place. Harold acted as mediator, but was compelled to agree to the banishment of Tostig, who was thenceforth his bitterest enemy.

On Jan. 6, 1066 Edward died, recommending Harold as his successor. He was accordingly elected at once and crowned. He won over the men of Northumbria, and prepared against the attacks which threatened on both sides. William challenged the crown, alleging both a bequest of Edward in his favour and Harold's oath, and prepared to invade England. From May to September, Harold kept men and ships in readiness on the south coast, but at last provisions failed and he returned to London. At this time Harald Hardrada of Norway, supported by Tostig in the north, invaded England. Together they sailed up the Humber, defeated Edwin and Morkere, and received the submission of York. Harold hurried northwards, and on Sept. 25 won a complete victory over the Northmen at Stamford Bridge, in which Tostig and Harald Hardrada were slain. Two days later Harold received news that William had landed at Pevensey, and he marched southward as fast as possible. He gathered his army in London from all southern and eastern England, while Edwin and Morkere held the north. The king then marched into Sussex, and engaged the Normans (Oct. 14, 1066) on the hill of Senlac near Battle (see HASTINGS, BATTLE OF). After a fight lasting all day the Normans had the victory; Harold, wounded by an arrow in the eye, and his two brothers Gyrth and Leofwine, lay dead on the field. Harold had three sons, Godwine, Edmund and Magnus, and two daughters, probably the children of Edith of the Swan-neck. Another son was named Ulf. By his wife Ealdgyth, who was sent for safety to Chester in 1066, he had a posthumous son, Harold, who took part in the expedition of Magnus Barefoot to the Scottish Isles in 1098. Harold's body is said to have been taken from the cairn of stones on the sea shore where it was originally buried to Waltham.

See E. A. Freeman, *History of the Norman Conquest of England* (6 vols., Oxford, 1871-79) in which the existing sources are fully utilised; Lytton's *Harold* is a brilliant historical novel, though not an impartial record.

HARP, the largest of the class of stringed instruments of which the strings are twanged or vibrated by the fingers. The harp is an instrument of beautiful proportions, approximating to a triangular form, the strings diminishing in length as they ascend in pitch. The mechanism is concealed within the different parts of which the instrument is composed: (1) the pedestal, or pedal-box, on which rest (2) the vertical pillar and (3) the inclined

convex body in which the sound-board is fixed (4) the curved neck, with (5) the comb concealing the mechanism for stopping the strings, supported by the pillar and the body.

The harp usually has 46 strings, of gut in the middle and upper registers, and of covered steel wire in the bass. The compass thus has a range of $6\frac{1}{2}$ octaves and in respect of notation the double stave is used as for the pianoforte. The modern harp with

double action is the only instrument with fixed tones, not determined by the ear or touch of the performer, which has separate notes for naturals, sharps, and flats, giving it an enharmonic compass. On the harp the appreciable interval between D# and E \flat can be played.

The harp in its normal condition is tuned to C \flat major; it rests with the performer to transpose it at will in a few seconds into any other key by means of the pedals, each of the pedals influencing one note of the scale throughout the compass. The harp is the instrument upon which transposition presents the least difficulty, for the fingering is the same for all keys. The quality of tone does not vary much in the different registers, but it has the greatest brilliancy in keys with many flats, for the strings are then open and not shortened by the mechanism.

BY COURTESY OF THE LIBRARIAN, TRINITY COLLEGE, DUBLIN

AN IRISH HARP OF THE MIDDLE AGES, WHICH IS TRADITIONALLY STATED TO HAVE BELONGED TO KING BRIAN BOIROIUMHE

It is possible to play on the ordinary harp all kinds of diatonic and arpeggio passages, but not chromatic, except in very slow tempo, on account of the time required by the mechanism of the pedals. Hence the invention of Pleyel's chromatic harp, patented in 1894 and improved in 1903 by Gustave Lyon, manager of the firm of Pleyel, Wolff & Co. This is an instrument practically without internal mechanism, constructed on the familiar lines of the pianoforte. There is a string for every chromatic semitone of the scale of C major, the white strings representing the white keys of the piano keyboard, and the black strings corresponding to the black keys. The strings cross halfway between neck and sound-board, this being the point where they are plucked; the left hand finds the black notes above, and the right hand below the crossing. The chromatic harp has many useful features, but it has shown no signs so far of displacing the ordinary double-action instrument.

History.—While the instrument is of great antiquity it is yet from northern Europe that the modern harp and its name are derived. The Greeks and Romans preferred to it the lyre in its different varieties, and a Latin writer, Venantius Fortunatus, described it in the 7th century A.D. as an instrument of the barbarians—"Romanusque lyra, plaudat tibi barbarus harpa." This is believed to be the earliest mention of the name, which is clearly Teutonic—O.H.G. *harapha*, A.S. *hearpe*, O. Norse, *harpa*.

The earliest delineations of the harp in Egypt point to its having had its origin in nothing more elaborate than the tense string of the warrior's or hunter's bow. Such an early instrument is the nanga, between which and the grand vertical harps in the frescoes of the time of Rameses III., more than 3,000 years old, there are varieties that permit one to bind the whole, from the simplest bow-form to the almost triangular harp, into one family.

The earliest records that we possess of the Celtic race, whether Gaelic or Cymric, give the harp a prominent place and harpists peculiar veneration and distinction. Upon a cross belonging to the ancient church of Ullard near Kilkenny, the date of which cannot be later than 830, a harp is plainly indicated; the sculpture is rude, but the instrument is clearly shown to have no front pillar. This remarkable structural likeness to the old harps of

Egypt and Assyria may be accidental, but permits the plausible hypothesis of Eastern descent.

As regards Wales, an old Welsh harp, not triple strung, exists, which bears a great resemblance to the Irish harp in neck, sound-board and sound-holes. But this does not imply derivation of the harp of Wales from that of Ireland or the reverse. There is no really good historical evidence, and there may have been a common or distinct origin on which ethnology only can throw light. The Welsh like the Irish harp was often an hereditary instrument, to be preserved with great care and veneration and used by the bards of the family, who were alike the poet-musicians and historians. A slave was not allowed to touch a harp, and it was exempted by the Welsh laws from seizure for debt.

The first pattern of the modern harp is discovered in German and Anglo-Saxon illuminated mss. as far back as the 9th century. No accidental semitones were possible with this instrument, unless the strings were shortened by the player's fingers. Then, in the 17th century, a Tirolese maker adapted hooks that, screwed into the neck, could be turned downwards to fix the desired semitone at pleasure. Later, somewhere about 1720, Hochbrucker, a Bavarian, invented pedals that, acting through the pedestal of the instrument, governed by mechanism the stopping, and thus left the player's hands free, a great advance. By a sequence of subsequent improvements, in which two Frenchmen named Cousineau took an important part, the pedal system was still further developed, to be brought finally to something like perfection in 1810 by the invention of the wonderfully ingenious double-action mechanism associated with the name of Sebastian Erard.

Notwithstanding these improvements, however, and the great beauty of tone the harp possesses, the domestic use of it in modern times has almost disappeared. But it still constitutes an indispensable feature of the orchestra and in this capacity has been employed with great effect by all the great masters, while during recent years its resources have been utilized to an ever-increasing extent in chamber music compositions.

HARPENDEN, an urban district of Hertfordshire, England, 25 m. N.W. by N. from London by rail. Pop. (1921) 6,738. It is an outlying residential district of London. The church of St. Nicholas is modern except the Perpendicular tower. In the Lawes testimonial laboratory there is a vast collection of samples of experimentally grown produce, annual products, ashes and soils. Sir John Bennet Lawes (d. 1900) provided an endowment of £100,000 for the perpetuation of the agricultural experiments which he inaugurated here at his seat of Rothamsted park, and the Rothamsted Experimental Station (*q.v.*) plays a foremost part in modern agricultural and botanical research. There are some rubber and hat manufactures.

HARPER, WILLIAM RAINEY (1856-1906), American Hebraist and educator, was born on July 26, 1856, at New Concord, O. His interest in Hebraic studies began in Muskingum college, at which he graduated in 1870. In 1875, when but 19 years of age, he received his Ph.D. at Yale for studies in the Indo-Iranian and Semitic languages. In 1880, after several years of academy teaching, he was given a professorship in Hebrew at the Baptist Union Theological seminary in Chicago. Here he founded *The*

Hebrew Student and *Hebraica* and organized the American Institute of Hebrew. He published a number of text-books and study helps for the teaching of Hebrew which found wide use. In 1886 he accepted a professorship in Semitic languages at Yale, and in 1889 was appointed also Woolsey professor of biblical literature, filling both positions simultaneously. He gave up his work at Yale, however, to accept in 1891, the presidency of the newly established University of Chicago. His liberal aims and comprehensive plans for the new university attracted wide attention and the president was able to raise sufficient funds to build adequate buildings and gather a notable faculty at the start. The university as a result was an immediate success. Harper remained its president and head of the department of Semitic languages until his death on Jan. 10, 1906.

Among his more important books are *Religion and the Higher Life* (1904); *A Critical and Exegetical Commentary on Amos and Hosea* (1905); *The Prophetic Element in the Old Testament* (1905); *The Trend in Higher Education* (1905).

See T. W. Goodspeed, *William Rainey Harper* (1928).

HARPER'S FERRY, a town of Jefferson county, W.Va., U.S.A., finely situated at the confluence of the Potomac and Shenandoah rivers (which here pass through a beautiful gorge in the Blue Ridge), 55 m. N.W. of Washington, D.C. Pop. (1920) 713. It is served by the Baltimore and Ohio railway, which crosses the Potomac here, and the Winchester and Potomac railway (Baltimore and Ohio) of which it is a terminus. Across the Potomac, on the north, rise the Maryland Heights; across the Shenandoah, on the West Virginia side, the Virginia or Loudoun Heights; and behind the town to the west the Bolivar Heights. A U.S. arsenal and armoury were established at Harper's Ferry in 1796, the site being chosen because of the good water-power; these were seized on Oct. 16, 1859, by John Brown (*q.v.*), the abolitionist, and some 21 of his followers. The engine-house in which Brown was captured was exhibited at the Columbian Exposition at Chicago and was later rebuilt on Bolivar Heights; a marble pillar, marked "John Brown's Fort," has been erected on its original site.

The first settlement here was made about 1747 by Robert Harper, who ran a ferry across the Potomac. The position of Harper's Ferry at the lower end of the Shenandoah Valley rendered it a place of strategic importance during the Civil War. On April 18, 1861, the day after Virginia passed her ordinance of secession, when a considerable force of Virginia militia under Gen. Kenton Harper approached the town—an attack having been planned in Richmond two days before—the Federal garrison of 45 men under Lieut. Roger Jones set fire to the arsenal and fled. Within the next few days large numbers of Confederate volunteers assembled here; and Harper was succeeded in command April 27 by "Stonewall" Jackson, who was in turn succeeded by Brig.-Gen. Joseph E. Johnston on May 23. Johnston thought that the place was unimportant, and withdrew when (June 15) the Federal forces under Gen. Robert Patterson and Col. Lew Wallace approached, and Harper's Ferry was again occupied by a Federal garrison. In Sept. 1862, during Gen. Lee's first invasion of the North, Gen. McClellan advised that the place be abandoned in order that the 10,000 men defending it might be added to his fighting force, but Gen. Halleck would not consent, so that when Lee needed supplies from the Shenandoah Valley he was blocked by the garrison, then under the command of Col. Dixon S. Miles. On Jackson's approach they were distributed as follows: about 7,000 men on Bolivar Heights, about 2,000 on Maryland Heights, and about 1,800 on the lower ground. On Sept. 13 Gen. Lafayette McLaws carried Maryland Heights and Gen. John G. Walker planted a battery on Loudoun Heights. On the 14th there was some fighting, but early on the 15th, as Jackson was about to make an assault on Bolivar Heights, the garrison, surrounded by a superior force, surrendered. The total Federal loss (including the garrisons at Winchester and Martinsburg) amounted to 44 killed (the commander was mortally wounded), 12,520 prisoners, and 13,000 small arms. For this terrible loss to the Union army the responsibility seems to have been Gen. Halleck's, though the blame was officially put on Col. Miles, who died immediately after the surrender. Jackson rejoined Lee on the following day in time to take part

DOUBLE-ACTION PRINCIPLE

in the battle of Antietam, and after the battle Gen. McClellan placed a strong garrison (the 12th Corps) at Harper's Ferry. In June 1863 the place was again abandoned to the Confederates on their march to Pennsylvania. After their defeat at Gettysburg, the town again fell into the hands of the Federal troops, and it remained in their possession until the end of the war. On July 4, 1864 Gen. Franz Sigel, who was then in command here, withdrew his troops to Maryland Heights, and from there resisted Early's attempt to enter the town and to drive the Federal garrison from Maryland Heights. Harper's Ferry was seriously damaged by a flood in the Shenandoah in Oct. 1878.

HARPIES (Gr. ἁρπυιαι the "snatchers"), fabulous creatures, probably wind-spirits although their presence as tomb-figures (e.g., on the famous Harpy Tomb of Xanthus in Lydia) makes it not impossible that they were ghosts; the two ideas are not wholly contradictory. In Homer they are plainly winds (*Odyssey*, xx. 66) which carried people away; as also *Odyssey*, i. 241 (the *harpyiai* have carried off Odysseus; i.e., he has been lost at sea). They are sometimes connected with the powers of the under-world; thus they carried off the daughters of Pandareus and gave them to the Erinyes as servants. Homer names one, Podarge (Swiftfoot), who seemed to be of equine nature, for she became by the West Wind the dam of Achilles' horses (*Iliad*, XVI, 150). Hesiod (*Theog.*, 265) mentions two, Aello, and Okypete (Stormwind and Swiftwing), daughters of Thaumias, and Electra the daughter of Oceanus.

These Harpies were in no way disgusting; later, especially in the Argonautic saga, they were represented as birds with the faces of women, horribly foul and loathsome. They are sent to punish Phineus for his ill-treatment of his children, or some other offence, and nearly starve him to death by carrying off most of his food and befouling the rest. Calais and Zetes (q.v.) deliver him and chase the Harpies away (Apollodorus, I, 120-123). Virgil imitates the episode in *Aen.*, III, 210 et seq.; he calls the chief Harpy Celaeno (Dark; cf. Hyginus, Fab. 14).

HARPIGNIES, HENRI (1819-1916), French landscape painter and engraver, born at Valenciennes on June 28, 1819. He took to painting comparatively late in life entering Achard's atelier in Paris at the age of 27. He went to Rome in 1850 returning to Paris in 1852. During the next few years he devoted himself to the painting of children in landscape setting. In 1863 he returned to Italy for two years working mainly in Rome, Naples and Capri. He came more and more under the influence of Corot and the water-colours executed during this period are among his finest work. He scored his first great success at the Salon, in 1861, with his "Lisière de bois sur les bords de l'Allier." After that year he was a regular exhibitor at the old Salon; in 1886 he received his first medal for "Le Soir dans la campagne de Rome," which was acquired for the Luxembourg Gallery. Many of his best works were painted at Hérisson in the Bourbonnais, as well as in the Nivernais and the Auvergne. He died on Aug. 28, 1916 at Saint Privé (Yonne) where he had settled in 1878. His landscapes are distinguished for constructive drawing and breadth of treatment; a silvery tone pervades them.

See Léonce Bénédite, *Notre Art, Nos Maîtres* (1923).

HARP-LUTE, or DITAL HARP, one of the many attempts to improve the guitar and to increase its compass, invented in 1798 by Edward Light, and taking the form of a kind of combined

guitar and harp. There are 12 catgut strings. A further improvement was patented in 1816 as the British harp-lute. Other attempts were the lyra-guitarre, which appeared in Germany at the beginning of the 19th century; the accord-guitarre, towards the middle of the same century; and the keyed guitar.

HARPOCRATES, originally an Egyptian deity, adopted by the Greeks, and worshipped in later times both by Greeks and Romans. In Egypt, Harpa-khruti, Horus the child, was one of the forms of Horus, the sun-god, the child of Osiris. He was supposed to carry on war against the powers of darkness, and hence Herodotus (ii. 144) considers him the same as the Greek Apollo. He was represented in statues with his finger on his mouth, a symbol of childhood. The Greeks and Romans, not understanding the meaning of this attitude, made him the god of silence (Ovid, *Metam.*, ix. 691), and as such he became a favourite deity with the later mystic schools of philosophy.

See articles by G. Lafaye in Daremberg and Saglio's *Dictionnaire des antiquités*, and by E. Meyer (s.v. "Horus") in Roscher's *Lexikon der Mythologie*.

HARPOCRATION, VALERIUS, Greek grammarian of Alexandria. He is possibly the Harpocraton mentioned by Iulius Capitolinus (*Life of Verus*, 2) as the tutor of Antonius Verus (2nd century A.D.); some authorities place him much later, on the ground that he borrowed from Athenaeus. He is the author of *Λεξικὸν* (or *Περ τῶν λέξεων*) τῶν δέκα ῥητόρων, a *Lexicon* or notes on well-known events and persons mentioned by the ten most famous orators, and explanations of legal and commercial expressions. As nearly all the lexicons to the Greek orators have been lost, Harpocraton's work, of which part is extant, is especially valuable. Amongst his authorities were the writers of Attiches (histories of Attica), the grammarian Didymus, Dionysius of Halicarnassus, and the lexicographer Dionysius, son of Tryphon. Nothing is known of an *Ἀνθηρῶν συναγωγὴ* a sort of anthology attributed to him by Suidas. A series of articles in the margin of a Cambridge ms. of the lexicon forms the basis of the *Lexicon rhetoricum Cantabrigiense* (see DOBREE, P.P.).

The best edition is by W. Dindorf (1853); see also J. E. Sandys, *History of Classical Scholarship*, i. (1906), p. 325; C. Boysen, *De Harpocratonis fontibus* (Kiel, 1876).

HARPOON, a barbed spear, particularly one used for spearing whales or other large fish, and either thrown by hand or fired from a gun (see WHALE-FISHERIES).

HARPSICHORD, a large keyboard instrument, belonging to the same family as the virginal and spinet, but having two, three or even four strings to each note, and a case of the harp or wing shape, afterwards adopted for the grand pianoforte. J. S. Bach's harpsichord, preserved in the museum of the *Hochschule für Musik* at Charlottenburg, has two manuals and four strings to each note, one 16ft., two 8ft. and one 4ft. By means of stops the performer has within his power a number of combinations for varying the tone and dynamic power. In all instruments of the harpsichord family the strings, instead of being struck by tangents as in the clavichord, or by hammers as in the pianoforte, are plucked by means of a quill firmly embedded in the centred tongue of a jack or upright placed on the back end of the key-lever. This plucking of the string produces the incisive tone peculiar to the harpsichord family. What these instruments gain in brilliancy of tone, however, they lose in power of expression and of accent. For fuller discussion of the harpsichord and its congeners see PIANOFORTE.

HARPY or HARPY-EAGLE, a large diurnal bird of prey, so named after the mythological monsters (see HARPIES). This bird, *Thrasaëtus harpyia*, inhabits America from south Mexico to Brazil. Its flight is slow and heavy, but it possesses an enormous bill and powerful talons. Except for a pectoral band, the head and lower parts are white; the upper parts are dark grey, banded with black, the wings dusky, the tail barred. On the head is an erectile crest. Its nearest allies are the eagles.

HARQUEBUS: see ARQUEBUS.

HARRAN, an ancient site of considerable strategic value on the River Belikh, in 37° N. 39° E. It lay on the old road from Nineveh westwards to the river crossing at Carchemish, in the

FROM HENRY BODDINGTON, "CATALOGUE OF MUSICAL INSTRUMENTS"

THE HARP-LUTE, A HYBRID INSTRUMENT, ONE OF SEVERAL INVENTED IN THE EARLY YEARS OF THE 19TH CENTURY, COMBINING FEATURES OF THE HARP, THE LUTE AND THE GUITAR

river valley, but close to the foothills and just north of the modern Syrian boundary. It is worthy of note that the modern caravan route goes north by Uriah, while the line chosen for the Baghdad railway skirted the hills, where the boundary runs and did not penetrate into the valley in which Harran stands. Its chief cult in Assyrian times was the moon god. The city was accepted as of considerable importance by the Assyrian kings. Crassus was here defeated and killed by the Parthians, and the Emperor Caracalla was murdered here. It appears to have remained of some importance down to the time of the Caliphate, but from that time onwards gradually fell into ruins. Its Roman name was Carrhae.

HARRATIN, black Berbers, dwelling in Tidikelt and other Saharan oases. Many, though blacker than the average negro, are of the Berber type, with European features and well-proportioned bodies. They are the result of an early crossing with the Sudanese negro. To-day they have all the pride of the Berbers (*q.v.*) and do not live with or intermarry among negroes.

HARRIER, the name of birds of prey forming the genus *Circus*. Harriers affect open country, feeding on snakes, frogs and other small vertebrates. The long wings and legs and the frill surrounding the lower part of the head serve to distinguish them. The group is almost world-wide in distribution.

The commonest species is the hen-harrier (*C. cyaneus*), ranging over N. Europe and Asia and showing great sexual dimorphism. Montague's harrier (*C. cineraceus*), with a more southerly range, shows the same phenomenon, but is distinguished by its longer wings. The American marsh-hawk (*C. hudsonius*) is very similar to the hen-harrier, but the male has rufous markings below. Other species occur in Europe, Africa, Asia, S. America, Australia and New Zealand.

Harriers build large nests on or near the ground, in marshes or similar situations. When the male brings food for the female during incubation, she leaves the nest, he drops the prey and she catches it in mid-air. In Great Britain, three species are found (the first two mentioned above and *C. aeruginosus*, the marsh-harrier), but all are now very rare. Harriers are extremely light (Montague, *Ornithological Dictionary*, 1802, gives the weight of the male as 130z.), but have a wing-spread of as much as 3ft.

HARRIMAN, EDWARD HENRY (1848-1909), American financier and railroad magnate, son of the Rev. Orlando Harriman, rector of St. George's Episcopal church, Hempstead (L.I.), was born at Hempstead, on Feb. 25, 1848. He became a broker's clerk in New York at an early age, and in 1870 was able to buy a seat on the New York Stock Exchange on his own account. He carefully mastered the situation affecting American railways. In this respect he was assisted by his friendship with Stuyvesant Fish, who, on becoming vice-president of the Illinois Central in 1883, brought Harriman upon the directorate, and in 1887, being then president, made Harriman vice-president; 20 years later it was Harriman who dominated the finance of the Illinois Central, and Fish, having become his opponent, was dropped from the board.

It was not till 1898, however, that his career as a great railway organizer began with his formation, by the aid of the bankers, Kuhn, Loeb & Co., of a syndicate to acquire the Union Pacific line, which was then in the hands of a receiver and was generally regarded as a hopeless failure.

THE HARPY (THRASAETUS HARPYIA), A LARGE BIRD OF PREY ALLIED TO THE EAGLE; IT IS A NATIVE OF CENTRAL AMERICA AND, ALTHOUGH SLOW OF FLIGHT, IS POWERFULLY ARMED WITH GREAT BILL AND TALONS

Having brought the Union Pacific out of bankruptcy into prosperity, he utilized his position to draw other lines within his control, notably the Southern Pacific in 1901. His abortive contest in 1901 with James J. Hill for the control of the Northern Pacific led to one of the most serious financial crises ever known on Wall Street. At his death, on Sept. 9, 1909, his influence was estimated to extend over 60,000m. of track. Harriman's methods excited the bitterest criticism, culminating in a stern denunciation from President Roosevelt himself in 1907.

HARRIMAN, a city of Roane county, Tenn., U.S.A., on the Emory river, 35m. W. by S. of Knoxville. It is served by the Louisville and Nashville, the Southern and the Tennessee Central railways. The population was 4,019 in 1920 (88% native white) and was estimated locally at 5,500 in 1928. The region abounds in coal, iron and timber, and peaches are extensively grown. The city has various manufacturing industries. Harriman was founded by a land company in 1890, and was chartered as a city in 1891.

HARRINGTON, EARLS OF. The first earl of Harrington (cr. 1742) was the diplomatist and politician, William Stanhope (c. 1690-1756), a younger son of John Stanhope of Elvaston, Derbyshire. Educated at Eton, William Stanhope was British ambassador in Spain from 1720 to 1729, and was created Baron Harrington in Jan. 1730. He was secretary of State for the northern department from 1730 to 1746 except for a short interval (1742-44), when he was president of the council. He was lord lieutenant of Ireland from 1747 to 1751, and he died in London on Dec. 8, 1756.

Leicester Fitzgerald Charles (1784-1862), 5th earl, was a soldier and a politician of advanced views, who worked with Lord Byron in the cause of Greek independence. He wrote *A Sketch of the History and Influence of the Press in British India* (1823); and *Greece in 1823 and 1824* (English ed. 1824, American ed. 1825).

HARRINGTON or HARINGTON, JAMES (1611-77), English political philosopher, was born in January 1611, the son of Sir Sapcotes Harrington of Rand, Lincolnshire, and great-nephew of the first Lord Harrington of Exton (d. 1615). In 1629 he entered Trinity college, Oxford, as a gentleman commoner. One of his tutors was the famous Chillingworth. After several years spent in travel, and as a soldier in the Dutch army, he returned to England and lived in retirement till 1646, when he was appointed to the suite of Charles I., at that time being conveyed from New-castle as prisoner. Though republican in his ideas, Harrington won the king's regard and esteem, and accompanied him to the Isle of Wight. He roused, however, the suspicion of the parliamentarians and was dismissed. After Charles's death Harrington wrote his *Oceana*, a work which pleased neither party. By order of Cromwell it was seized when passing through the press. But, by the favour of the Protector's favourite daughter, Mrs. Claypole, the work was restored to him, and appeared in 1656, dedicated to Cromwell. The views embodied in *Oceana*, particularly that bearing on vote by ballot and rotation of magistrates and legislators, Harrington and others (who in 1659 formed a club called the "Rota") endeavoured to push practically, but with no success. In November 1661, by order of Charles II., Harrington was arrested on a charge of conspiracy, and was thrown into the Tower. No public trial could be obtained, and when at length his sisters obtained a writ of *habeas corpus* he was secretly removed to St. Nicholas island off Plymouth. He died on Sept. 11, 1677, and was buried next to Sir Walter Raleigh in St. Margaret's, Westminster.

The *Oceana* is the exposition of an ideal constitution, "Oceana" being England, and the lawgiver Olphaus Megaletor, Oliver Cromwell. The main ideas are: that the determining element of power in a state is property generally, property in land in particular; and that the executive power ought not to be vested for any considerable time in the same men or class of men. Harrington recommends an agrarian law, limiting the portion of land held to that yielding a revenue of £3,000, and consequently insisting on particular modes of distributing landed property. As a means to the second object he lays down the rule of rotation by ballot.

His *Works* were edited with biography by John Toland in 1700;

Toland's edition, with additions by Birch, appeared in 1747, and again in 1771. *Oceana* was reprinted by Henry Morley in 1887. See H. F. Russell-Smith, *Harrington and his Oceana* (1914). Harrington has often been confused with his cousin Sir James Harrington, a member of the commission which tried Charles I., and afterwards excluded from the acts of pardon.

HARRIOT or HARRIOTT, THOMAS (1560-1621), English mathematician and astronomer, was born at Oxford in 1560. After studying at St. Mary hall, Oxford, he became tutor to Sir Walter Raleigh, who appointed him in 1585 to the office of geographer to the second expedition to Virginia. Harriot published an account of this expedition in 1588, which was afterwards reprinted in Hakluyt's *Voyages*. On his return to England (1587) he resumed his mathematical studies. He materially assisted the development of algebra, and introduced symbols and notation still used, e.g., x^3 for *xxx*. A manuscript of Harriot's entitled *Ephemeris chrysometria* is preserved in Sion college, near London; and his *Artis analyticae praxis ad aequationes algebraicas resolvendas* was published at London in 1631. He died in London on July 2, 1621.

See Charles Hutton, *Mathematical and Philosophical Dictionary* (1815); J. E. Montucla, *Histoire des mathématiques* (1758), and Wallis, *History of Algebra* (1685).

HARRIS, GEORGE, 1ST BARON, CT. 1815 (1746-1829), British general, was the son of the Rev. George Harris, curate of Brasted, Kent, and was born on March 18, 1746. Educated at Westminster school and at the Royal Military Academy, Woolwich, he was commissioned to the Royal Artillery in 1760, transferring to an ensigncy in the 5th foot (Northumberland Fusiliers) in 1762. His first active service was in the American War of Independence, his next under Major-General Medows at Santa Lucia in 1778-1779, after which his regiment served as marines in Rodney's fleet. After commanding the 5th in Ireland for some years, he exchanged and went with General Medows to Bombay, and served in India until 1792. In 1794 he was again in India, and in 1796 became local lieutenant-general in Madras. Up to 1800 he commanded the troops in the presidency, and for a short time he exercised the civil government as well. In December 1798 he was appointed by Lord Wellesley, the governor-general, to command the field army against Tippoo Sahib (*q.v.*), and in a few months Harris reduced the Mysore country and stormed the great stronghold of Seringapatam. He returned home in 1800, and attained the rank of full general in 1812. Lord Harris died at Belmont in May 1829.

See Rt. Hon. S. Lushington, *Life of Lord Harris* (London, 1840).

HARRIS, JAMES RENDEL (1852-), English scholar, born at Plymouth, studied at Close college, Cambridge, of which he became a fellow. He held professorships at Johns Hopkins university and at Haverford college, U.S.A., from 1882 to 1892, was then professor of palaeography (1893-1903) at Cambridge, spent a year at Leyden as professor of theology, and was director of studies at the Friends' Settlement at Woodbrooke, near Birmingham, from 1903 to 1918. In 1918 he became curator of mss. at the Ryland library, Manchester. Rendel Harris travelled extensively in the Near East in search of mss. He is the author of a long series of works dealing with textual criticism of the biblical books, and of sacred books outside the canon of scripture, and of works on various Mediterranean cults. His works include: *Biblical Fragments from Mount Sinai* (1890); *The Diatessaron* (1890); *Lectures on the Western Text of the New Testament* (1894); *Origin of the Cult of Dionysus* (1915); *Further Traces of Hittite Migration* (1927).

HARRIS, JOEL CHANDLER (1848-1908), American author, was born in the vicinity of Eatonton, Putnam county (Ga.), Dec. 9, 1848. As apprentice on a weekly plantation paper near his home, he obtained the real basis for his later work. Later he continued his newspaper work at Macon, New Orleans, Forsyth (Ga.) and Savannah, finally spending 24 years on the staff of the *Atlanta Constitution*. Although he had earlier established a reputation as a capable newspaper man and brilliant paragrapher, it was through his negro sketches contributed to this paper that he first became known throughout the nation. *Uncle Remus: His Songs and Sayings* was published in book form in

1880 and was followed by *Nights with Uncle Remus* (1883), *Daddy Jake, the Runaway, and Short Stories Told after Dark* (1889), *Uncle Remus and His Friends* (1892) and later volumes of like nature, books which endeared the picturesque old storyteller and his animal characters to young and old. A series of children's books began with *Little Mr. Thimblefinger and His Queer Country* (1894). *Mingo, and other Sketches in Black and White* (1884), *Free Joe, and Other Georgian Sketches* (1887), *Sister Jane, Her Friends and Acquaintances* (1896) and *Gabriel Tolliver* (1902) reveal Harris' ability to vitalize other southern types. *On the Plantation* (1892; published in London as *A Plantation Printer*) is one of the most interesting of his books because of its autobiographic nature. Harris often spoke of himself as simply a mouthpiece and a "cornfield" writer. As a man who has done much, however, to immortalize the faithfulness, the humour, the kindness and quaint philosophy of the negro, in short, as the creator of Uncle Remus, he has won for himself a secure place in American literature. He died in Atlanta, July 3, 1908.

See Julia Collier Harris, *The Life and Letters of Joel Chandler Harris* (1918), which contains a bibliography.

HARRIS, JOHN (c. 1666-1719), English writer. He is best known as the editor of the *Lexicon technicum*, or *Dictionary of the Arts and Sciences* (1704), which ranks as the earliest of the long line of English encyclopaedias, and as the compiler of the *Collection of Voyages and Travels* which passes under his name. He was born about 1666, probably in Shropshire, and was a scholar of Trinity college, Oxford, from 1684 to 1688. He held the vicarage of Icklesham in Sussex, and subsequently the rectory of St. Thomas, Winchelsea. In 1698 he delivered the seventh series of the Boyle lectures—*Atheistical Objections against the Being of God and His Attributes fairly considered and fully refuted*. Between 1702 and 1704 he gave at the Marine coffee house, Birchin lane, London, the mathematical lectures founded by Sir Charles Cox. The friendship of Sir William Cowper, afterwards lord chancellor, secured for him a series of church preferments. He showed himself an ardent supporter of the Government, and engaged in a bitter quarrel with the Rev. Charles Humphreys, afterwards chaplain to Dr. Sacheverel who held him up to ridicule in *The Picture of a High-flying Clergyman* (1716). Harris was one of the early members of the Royal Society, and for a time acted as vice-president. He died on Sept. 7, 1719.

HARRIS, SIR WILLIAM SNOW (1791-1867), English electrician, was born at Plymouth on April 1, 1791. He set up as a medical practitioner in Plymouth but gave this up to study electricity. In 1820 he invented a new method of arranging the lightning conductors of ships, but the method was not adopted by the Government for the Royal navy until 1847. He was then knighted and later received a grant of £5,000. Harris published a number of papers on general electricity and was the author of manuals on *Electricity*, *Galvanism* and *Magnetism* published between 1848 and 1856. He died at Plymouth on Jan. 22, 1867.

Harris' *Treatise on Frictional Electricity* was published posthumously in 1867, with a memoir of the author by Charles Tomlinson.

HARRIS, WILLIAM TORREY (1835-1909), American educationalist, was born in North Killingly, Conn., on Sept. 10, 1835. He studied at Phillips academy, Andover, Mass., and entered Yale, but left in his junior year to teach in St. Louis, Mo., being city superintendent of schools from 1867 until 1880. There he grew interested in modern German philosophy; he founded in 1867 *The Journal of Speculative Philosophy*; and later became a lecturer at the Concord School of Philosophy. In 1873, with Miss Susan E. Blow, he established in St. Louis the first permanent public school kindergarten in America. From 1889 to 1906 he was U.S. commissioner of education. Besides being a contributor to the magazines and encyclopaedias on educational and philosophical subjects, he wrote *An Introduction to the Study of Philosophy* (1889); *The Spiritual Sense of Dante's Divina Commedia* (1889); and *Psychologic Foundations of Education* (1898); he interpreted Hegel to American readers; he edited Appleton's *International Education Series* and Webster's *New International Dictionary*. He died in Providence, R.I., on Nov. 5, 1909.

See Henry R. Evans, "A List of the Writings of William Torrey

Harris" in the *Report of the Commissioner of Education for 1907* (vol. I, 1908) and J. S. Roberts, *William T. Harris, a Critical Study of His Educational and Related Philosophical Views* (1924).

HARRISBURG, a city in the rich agricultural and coal-mining region of southern Illinois, U.S.A.; the county seat of Saline county. It is on Federal highway 45, and is served by the Big Four and the Southern Illinois Railway and Power company railways. The population was 7,125 in 1920 (90% native white), and was estimated locally at over 12,000 in 1928. The city has flour mills, brick and tile works, saw and planing mills. It was settled about 1840 and incorporated in 1876.

HARRISBURG, the capital city of Pennsylvania, U.S.A., and the county seat of Dauphin county, on the E. bank of the Susquehanna river, 105m. W. by N. of Philadelphia. It is at the intersection of Federal highways 11, 15, 22, 209 and 230, and of many State roads, and is served by the Pennsylvania and the Reading railways. The population was 75,917 in 1920 (87.6% native white), and was estimated at 85,700 in 1928. Including contiguous boroughs, the population of the metropolitan area in 1928 was over 125,000.

The river here is 1m. wide. Ordinarily it is shallow, and dotted with islets, but after a moderate rain it rises 4 to 6 feet. The area of the city is 9 square miles. Along the river bank for 5m. extends a parkway (Front street), bordered by fine residences, including the governor's mansion. Below the parkway, at the edge of the river, is a concrete promenade, on the top of a large intercepting sewer, with steps leading down into the water. On a large island is the municipal bathing beach, and during the summer huge flat-bottomed dance-boats ply up and down the river at night. A park system embracing 1,100ac. almost encircles the city. There are public golf links and tennis courts, and 17 supervised playgrounds for children. At right angles to Front street is State street, 120ft. wide, running east to Capitol park (16ac.) in the heart of the city. The present capitol, dedicated in 1906, was erected at a cost of \$13,000,000 to replace one burned in 1897. It is a fine building, with a dome modelled after that of St. Peter's at Rome. At the main entrance are groups of statuary by George Grey Barnard. The bronze doors are decorated in relief with scenes from the State's history. The rotunda is paved with tiles made at Doylestown in the style of the pottery of the early Moravian settlers. There are stained-glass windows by W. B. van Ingen; and mural decorations by him and by Edwin A. Abbey, John W. Alexander and Violet Oakley. Adjoining is the State library and museum, containing 150,000 volumes, the State records and thousands of historic exhibits and relics. A large tract behind the capitol has been transformed into a park, as a site for four State office buildings, two of which had been erected by 1928. A viaduct across the Pennsylvania railroad tracks is under construction by the State as a memorial to the Pennsylvania men who served in the World War. A comprehensive city plan is in process of development. The assessed valuation of property subject to taxation was \$86,918,210 in 1928.

For several years before 1902 Harrisburg suffered from impure water, a bad sewerage system and poorly paved and dirty streets. In 1902 a non-partisan mayor was elected, and a vigorous programme of improvement undertaken. Since then the city has spent over \$14,000,000 in major civic improvements, including streets, schools, sewers, bridges, parks, fire apparatus, filtration and incineration plants, elimination of grade crossings and development of civic centres. The private charitable agencies are associated, for joint raising of funds and other purposes, in a welfare federation which has 25,000 contributors. A State hospital for the insane, established in 1845 through the efforts of Dorothea Lynde Dix, is situated here.

Harrisburg is a concentration point for the Pennsylvania railroad, and both the Pennsylvania and the Reading have large freight-classification yards here. Coal and iron abound in the vicinity, and immense quantities of coal for power plants are salvaged from the bed of the river. The city has numerous manufacturing establishments (204 in 1925, according to a State census), with an annual output valued at \$46,000,000. The most important products are steel and iron, knit goods, tobacco and cigars, con-

fectionery and ice-cream, food products, printing, boilers and engines, and book-keeping and book-binding machinery. The railroads employ about 10,000 persons; the factories about 9,000; and 4,400 State employees live in the city. Its immediate trading area has a population of 250,000. Bank clearings in 1927 amounted to \$247,870,414.

The first settler here was John Harris, about 1726, a trader attracted to the site because it was an easy place to ford the Susquehanna. In 1753 his son began to operate a ferry, and the settlement was known as Harris's Ferry until 1785, when the younger Harris laid out a town and named it Harrisburg. In the same year it was made the seat of the new county of Dauphin, and its name was changed to Louisburg; but in 1791, when it was incorporated as a borough, the old name was resumed. As the result of efforts extending over 25 years, it was made the capital of the State in 1812. In 1860, when the population was 13,405, it was chartered as a city. A commission form of government was adopted in 1913. A convention held here in 1827, in the interest of securing legislative aid for the woollen manufactures of New England, framed a programme which did much to bring about the passage by Congress of the famous high tariff act of 1828.

HARRISMITH, a town in the Orange Free State, South Africa, situated in 28° 15' S., 29° 9' E., 261 m. from Durban; altitude, 5,321 feet. Pop. (1921), 2,546 Europeans, 3,654 non-Europeans. It is situated near the Wilge river, and is an important trading centre. It was formerly a military centre. The town is laid out in wide, straight streets, many of which are lined with trees. The houses are built of local sandstone. A good water supply is led in pipes from the Platberg, a mountain about 8,000 ft. high, which rises immediately to the north of the town. The surrounding district is well watered, the annual rainfall being about 27 inches. Owing to the dry atmosphere, the strong sunlight and the comparative freedom from dust, the climate is beneficial to those suffering from chest troubles. In winter the nights may be very cool, and even in daytime the weather may be very bracing when the wind is blowing from the south or off the snows on the Drakensberg and Malutis. The town is named after its founder, Sir Harry Smith. Wool and hides are the principal productions. (R. U. S.)

HARRISON, BENJAMIN (1833-1901), the 23rd president of the United States, was born at North Bend, near Cincinnati, O., on Aug. 20, 1833. His great-grandfather, Benjamin Harrison of Virginia (c. 1740-91), was a signer of the Declaration of Independence. His grandfather, William Henry Harrison (1773-1841), was 9th president of the United States. His father, John Scott Harrison (1804-78), represented his district in the National House of Representatives in 1853-57. Benjamin's youth was passed upon the ancestral farm, and as opportunity afforded he attended school in the log school-house near his home. He was prepared for college by a private tutor, studied for two years at the Farmers college, near Cincinnati, and in 1852 graduated from Miami university. From his youth he was diligent in his studies and a great reader, and during his college life showed a marked talent for extemporaneous speaking. He pursued the study of law, partly in the office of Bellamy Storer (1798-1875), a leading lawyer and judge of Cincinnati, and in 1853 he was admitted to the bar. At the age of 21 he removed to Indianapolis, Indiana. He had but one acquaintance in the place, the clerk of the Federal court, who permitted him to occupy a desk in his office and place at the door his sign as a lawyer. Within a few years he took rank among the leading members of the profession at a bar which included some of the ablest lawyers of the country.

His legal career was early interrupted by the Civil War. His whole heart was enlisted in the anti-slavery cause, and during the second year of the war he accepted a commission from the governor of the State as second-lieutenant and speedily raised a regiment. He became its colonel, and as such continued in the Union army until the close of the war, and on Jan. 23, 1865, was breveted a brigadier-general of volunteers for "ability and manifest energy and gallantry in command of brigade." He participated with his regiment in various engagements during Gen. Don Carlos Buell's campaigns in Kentucky and Tennessee in 1862 and 1863; took

part in Gen. W. T. Sherman's march on Atlanta in 1864 and in the Nashville campaign of the same year; and was transferred early in 1865 to Sherman's army in its march through the Carolinas. As the commander of a brigade he served with particular distinction in the battles of Kenesaw Mountain (June 29-July 3, 1864), Peach Tree Creek (July 20, 1864) and Nashville (Dec. 15-16, 1864).

Allowing for this interval of military service, he applied himself exclusively for 24 years to his legal work. He was a devoted member of the Republican Party, but not a politician in the strict sense. He took a deep interest in the campaign which resulted in the election of James A. Garfield as president, and was offered by him a place in his cabinet; but this he declined, having been elected a member of the U.S. Senate, in which he took his seat on March 4, 1881. He was chairman of the committee on territories, and took an active part in urging the admission as States of North Dakota, South Dakota, Washington, Idaho and Montana, which finally came into the Union during his presidency. He served also on the committee on military and Indian affairs, the committee on foreign relations and others, was prominent in the discussion of matters brought before the Senate from these committees, advocated the enlargement of the navy and the reform of the civil service, and opposed the pension veto messages of President Cleveland. Having failed to secure a re-election to the Senate in 1887, Harrison was nominated by the Republican Party for the presidency in 1888, and defeated Grover Cleveland, the candidate of the Democratic Party, receiving 233 electoral votes to Cleveland's 168. Among the measures and events distinguishing his term as president were the following: the meeting of the Pan American Congress at Washington; the passage of the McKinley tariff bill and of the Sherman silver bill of 1890; the suppressing of the Louisiana lottery; the enlargement of the navy; further advance in civil service reform; the convocation by the United States of an international monetary conference; the establishment of commercial reciprocity with many countries of America and Europe; the peaceful settlement of a controversy with Chile; the settlement of difficulties with Germany concerning the Samoan islands, and the adjustment by arbitration with Great Britain of the Bering sea fur-seal question. His administration was marked by a revival of American industries and a reduction of the public debt. He was nominated by his party in 1892 for re-election, but was defeated by Cleveland, this result being due, at least in part, to the strikes which occurred during the presidential campaign and arrayed the labour unions against the tariff party.

After leaving public life he resumed the practice of the law, and in 1898 was retained by the Government of Venezuela as its leading counsel in the arbitration of its boundary dispute with Great Britain. In this capacity he appeared before the international tribunal of arbitration at Paris in 1899. He wrote *This Country of Ours* (1897), treating of the organization and administration of the Government of the United States, and a collection of essays by him was published posthumously, in 1901, under the title *Views of an Ex-President*. He died at Indianapolis on March 13, 1901. Harrison's distinguishing trait of character, to which his success is to be most largely attributed, was his thoroughness. He was somewhat reserved in manner, and this led to the charge in political circles that he was cold and unsympathetic; but no one gathered around him more devoted and loyal friends, and his dignified bearing in and out of office commanded the hearty respect of his countrymen.

President Harrison was twice married; in 1853 to Miss Caroline Lavinia Scott, by whom he had a son and a daughter, and in 1896 to Mrs. Mary Scott Lord Dimmock, by whom he had a daughter.

A "campaign" biography was published by Lew Wallace (Philadelphia, 1888), and a sketch of his life may be found in *Presidents of the United States* (1894), edited by James Grant Wilson. See also U.S. Government Printing Office, *Public Papers and Addresses of Benjamin Harrison* (1893); and W. W. Thorton, "Benjamin Harrison a Lawyer and an Orator," in *Green Bag*, vol. xiv., pp. 49-57 (1902). (J. W. F.)

HARRISON, FREDERIC (1831-1923), English jurist and man of letters, was born in London on Oct. 18, 1831. Members

of his family (originally Leicestershire yeomen) had been lessees of Sutton Place, Guildford, of which he wrote an interesting account (*Annals of an Old Manor House*, 1893). He was educated at King's College school and at Wadham college, Oxford, where, after taking a first-class in *Literae Humaniores* in 1853, he became fellow and tutor. He was called to the bar in 1858, and practised in equity cases. He worked at the codification of the law with Lord Westbury. His special interest in legislation for the working classes led to his appointment on the Trades Union Commission of 1867-69; he was secretary to the commission for the digest of the law, 1869-70; and was from 1877 to 1889 professor of jurisprudence and international law under the council of legal education. Of his separate publications at this time the most important are his lives of Cromwell (1888), William the Silent (1897), Ruskin (1902) and Chatham (1905); his *Meaning of History* (1862; enlarged 1894) and *Byzantine History in the Early Middle Ages* (1900); and his essays on *Early Victorian Literature* (1896) and *The Choice of Books* (1886) are remarkable alike for generous admiration and good sense. In 1889 he was elected an alderman of the London County Council, but resigned in 1893. In 1870 he married Ethel Berta, daughter of Mr. William Harrison, by whom he had four sons.

Harrison was president of the English Positivist Committee from 1880 to 1905. In his last book *De Senectute* (1923), which he did not live to see published, he re-affirmed his life-long principle and attachment to the religion of Auguste Comte, and no estimate can do him justice which does not take into account the essentially religious character of his life, of which all his written works may be said to be a contributory expression. Though Frederic Harrison originally came into prominence in the days (1850-80) of fighting agnosticism, he was never himself an "agnostic," and in fact was severely criticised by the leading agnostics, notably by Huxley and Herbert Spencer, etc.; moreover, as Positivist, he was a republican in spirit and, what was new at that period, a sociologist. It was this positivist sociology which caused him as a young man to espouse the cause of trade unionism, which he did with such energy and legal skill as adviser to the Royal Commission on Trade Unions in 1867, that he was really the inspirer and founder of the trade union law as it existed from 1868 to 1906. None the less, his religion did not permit him to embark upon a public career. He virtually retired from politics (in the party sense) and from legal practice in mid-life, this latter very largely as the enforced consequence of his pioneer fight on behalf of trade unionism, and took to letters.

At the age of 80 he published his *Autobiographic Memoirs* (2 vols., 1911). Among the books that flowed almost annually from his pen may be mentioned: *Memories and Thoughts* (1906); *National and Social Problems* (1908); *Tennyson, Ruskin, Mill and other Literary Estimates* (1899); *George Washington, etc.* (1901); *Theophano* (1904), a "romantic monograph" of the 10th century; *Nicephorus* (1906), a verse tragedy; *The Creed of a Layman* (1907); *Realities and Ideals* (1908); *Novissima Verba* (1920); *De Senectute* (1923). As an historian Frederic Harrison did not belong to the modern school of specialization, and ranks as a "literary-historian"; as essayist, he excelled, occupying a distinguished place both for the soundness of his judgment and for the vigour and clarity of his style. Politically, he stood in the position of an unofficial pro-consul, and for some years before the World War he repeatedly warned his countrymen of the impending crisis arising out of the armed system of Europe, and of the necessity of British preparation to meet it. An article he wrote in *The English Review* in 1913 proved to be only too prophetic. During the War he stood unflinchingly for victory and for the cause of France. His son, René, was killed in Flanders in 1915.

Frederic Harrison's life may be described as an attempt to introduce Comte's Humanist sociology into England, to which end he devoted all his energies. For 20 years he was the leader of English Positivism and regularly lectured at Newton Hall, being also a co-founder of and contributor to *The Positivist Review*. His political views were zealously put forward in that organ. He was not a Radical in the party sense though always a Liberal

in spirit. Internationally he was a life-long supporter of France, and in 1870 vehemently urged British support of Gambetta as against Bismarckianism. If he was a "Little Englander," it was because of his championship of the "Little Peoples," and during the Boer War his pronounced anti-jingoism led him into acute controversy. Publicly, his attitude was often misunderstood for that reason. He may be said to have been a republican in spirit, a humanist by conviction and a "meliorist" as politician.

Frederic Harrison had not originally wished to found a Positivist centre or sect, but after the secession of Dr. Congreve on the crucial issue of allegiance to French Comtists, he virtually had no alternative, and it was thus that Newton Hall came into being. As head of that body, Frederic Harrison found copious use for his scholastic knowledge and energies as lecturer and teacher, and though in that position he was "labelled," the sincerity and disinterestedness of his opinions were so universally recognized that his public moral authority did not lose through isolation. In this way he occupied a kind of "chair" of public morals, such as is hardly conceivable in any other country, hence his unflinching war determinism in 1914 caused him to be more popularly known and appreciated in extreme old age than had been the case during the Victorian epoch when, as a humanist, he found himself neither on the one side nor the other of the great Victorian struggle for "liberty of thought," the foundation of which intellectually had been laid by Auguste Comte and Charles Darwin.

In this great battle of "reason," which started at Oxford, Harrison played a conspicuous part, though never as an iconoclast and in interest, spiritually; *i.e.*, outside the intellectual ethicism arising out of the new criticism, for he neither adhered to the utilitarianism of Mill nor to the "dry light" of the debaters in the famous Metaphysical Society of which he was a member. Positivism was at that time regarded as a "heresy" both by orthodoxy and by the agnostics, and in the controversies that ensued Harrison drifted somewhat out of the movements of his time. He was perhaps the last survivor of the "great" Victorians. He will be remembered as a supreme individualist, a slashing controversialist, as a practical idealist and citizen. Thus he consistently advocated the return of the "Elgin Marbles" to Greece on the ground that the statuary belonged to the historical religion of the Greeks. He was a friend of President Roosevelt and twice lectured in the United States. He was at his best as critic of life and art in relation of the past to the present, which was Comte's "law" of continuity, but Harrison was alive to the academic weaknesses in Comte's *Polity* and rejected any dogma. In his latter years he resided at Bath, of which city he was given the freedom. He died there on Jan. 14, 1923. He had refused all titles or "honours." His ashes, mingled with those of his wife, repose in an urn placed in the chapel of Wadham college, Oxford, according to his last wishes.

See Austin Harrison, *Frederic Harrison: Thoughts and Memories* (1925).

His son AUSTIN HARRISON (1873-1928) was joint editor of the *Observer* (1905-08) and as editor of the *English Review* (1910-23), was instrumental in making known to the public a number of writers who have since become famous. His works include *The Kaiser's War* (1914) and *Pandora's Hope* (1925).

HARRISON, JANE ELLEN (1850-1928), English scholar, was born at Cottenham, Yorkshire, on Sept. 9, 1850, and was educated at Cheltenham college and Newnham college, Cambridge. She took a place in the moral sciences tripos equivalent to the second place. Her life-work was done in art and archaeology. She brought to the study of Greek art and of Greek religion great enthusiasm, a generous spirit and considerable learning. A humanist in the best sense she was all her life susceptible to new ideas and never allowed her mind to go stale. Thus in her old age she began the study of Persian. Jane Harrison returned to Newnham as fellow and lecturer in classical archaeology in 1900, and gave a great impetus to classical study there. Her most important work was *Prolegomena to the Study of Greek Religion* (1903). Others were: *Myths of the Odyssey in Art and Literature* (1882); *Introductory Studies in Greek Art* (1885); *Themis* (1912); *Ancient*

Art and Ritual (1913); and *Epilegomena to the Study of Greek Religion* (1921). She died in London on April 16, 1928.

HARRISON, JOHN (1693-1776), English horologist, was the son of a carpenter, and was born at Faulby, near Pontefract. In 1715 he made a clock with wooden wheels, which is in the patent museum at South Kensington, and in 1726 he devised his ingenious "gridiron pendulum," which maintains its length unaltered in spite of variations of temperature. Another invention of his was a recoil clock escapement in which friction was reduced to a minimum, and he was the first to employ the commonly used and effective form of "going ratchet," which is a spring arrangement for keeping the timepiece going at its usual rate during the interval of being wound up.

In 1713 the British government offered rewards of £10,000, £15,000 and £20,000 to any who should construct chronometers that would determine the longitude within 60, 40 and 30 m. respectively. Harrison, after making several watches, went up to London in 1761 with one which he considered almost perfect. His son William was sent on a voyage to Jamaica to test it; and on his return to Portsmouth in 1762, it was found to have lost only 1 minute 54½ seconds. This was surprisingly accurate, as it determined the longitude within 18 m., and Harrison claimed the full reward of £20,000; but though from time to time he received sums on account, it was not till 1773 that he was paid in full. In these watches compensation for changes of temperature was applied for the first time by means of a "compensation-curb," designed to alter the effective length of the balance-spring in proportion to the expansion or contraction caused by variations of temperature. Harrison died in London on March 24, 1776.

See his *The Principles of Mr Harrison's Timekeeper*, published by order of the Commissioners of Longitude. (1767).

HARRISON, THOMAS (1606-1660), English parliamentarian, a native of Newcastle-under-Lyme, Staffordshire, the son of a butcher and mayor of that town, enlisted in 1642 in Essex's lifeguards, became major in Fleetwood's regiment of horse under the earl of Manchester, was present at Marston Moor, at Naseby, Langport and at the taking of Winchester and Basing, as well as at the siege of Oxford. In 1646 he was returned to parliament for Wendover, and served in Ireland in 1647 under Lord Lisle, returning to England in May, when he took the side of the army in the dispute with the parliament and obtained from Fairfax a regiment of horse. In November he opposed the negotiations with the king, whom he styled "a man of blood" to be called to account, and he declaimed against the House of Lords. At the surprise of Lambert's quarters at Appleby on July 18, 1648, in the second civil war, he was severely wounded. He showed a special zeal in bringing about the trial of the king. Charles was entrusted to his care on being brought up from Hurst Castle to London. Harrison was assiduous in his attendance at the trial, and signed the death-warrant. He took part in suppressing the royalist rising in the midlands in May 1649, and in July was appointed to the chief command in South Wales, where he is said to have exercised his powers with exceptional severity. On Feb. 20, 1651, he became a member of the council of state, and during Cromwell's absence in Scotland held the supreme military command in England. He failed to stop the march of the royalists into England at Knutsford on Aug. 16, 1651, but after the battle of Worcester he pursued the fugitives. Later he pressed on Cromwell the necessity of dismissing the Long Parliament, and it was he who at Cromwell's bidding, on April 20, 1653, laid hands on Speaker Lenthall and compelled him to vacate the chair. He was president of the council of thirteen which now exercised authority. Harrison belonged to the faction of Fifth Monarchy men, whose political ideals were entirely destroyed by Cromwell's assumption of the protectorate. He was deprived of his commission on Dec. 22, 1653, and on Feb. 3, 1654, was ordered to confine himself to his father's house in Staffordshire. He was imprisoned for a short time in September, and on Feb. 15, 1655, he was imprisoned in Carisbrooke Castle, being liberated in March 1656. At the Restoration, Harrison, who was excepted from the Act of Indemnity, refused to take any steps to save his life, to give any undertaking not to conspire against the government or to flee. He was arrested in Stafford-

shire in May 1660, and executed at Charing Cross on Oct. 13, 1660.

Richard Baxter, who was acquainted with him, describes Harrison as "a man of excellent natural parts for affection and oratory, but not well seen in the principles of his religion; of a sanguine complexion, naturally of such a vivacity, hilarity and alacrity as another man hath when he hath drunken a cup too much, but naturally also so far from humble thoughts of himself that it was his ruin." Cromwell also complained of his excessive eagerness. "Harrison is an honest man and aims at good things, yet from the impatience of his spirit will not wait the Lord's leisure but hurries me on to that which he and all honest men will have cause to repent."

See C. H. Simpkinson, *Life of Harrison* (1905).

HARRISON, THOMAS ALEXANDER (1853-), American painter, was born in Philadelphia, Jan. 17, 1853. He was a pupil of the Pennsylvania Academy of Fine Arts and of the École des Beaux-Arts, Paris, whither he went in 1878, having previously been with a U.S. Government survey expedition on the Pacific coast. Chafing under the restraints of the schools, he went into Brittany, and at Pont Aven and Concarneau turned his attention to marine painting and landscape. In 1882 he sent a figure-piece to the Salon, a fisher boy on the beach, which he called, "Châteaux en Espagne." This piece attracted attention, and in 1885 he received an honourable mention, the first of many awards conferred upon him, including the Temple gold medal (Pennsylvania Academy of Fine Arts, Philadelphia, 1887), first medal, Paris Exhibition (1889), and medals in Munich, Brussels, Ghent, Vienna and elsewhere.

HARRISON, WILLIAM (1534-1593), English topographer and antiquary, was born in London on April 8, 1534. He was inducted early in 1559 to the rectory of Radwinter, Essex, on the presentation of Sir William Brooke, Lord Cobham, to whom he had formerly acted as chaplain; and from 1571 to 1581 he held from another patron, Francis de la Wood, the living of Wimbish in the same county. He became canon of Windsor in 1586, and his death and burial are noted in the chapter book of St. George's chapel on April 24, 1593.

His famous and amusing *Description of England* was undertaken for the queen's printer, Reginald Wolfe, who designed the publication of "an universall cosmographie of the whole world . . . with particular histories of every knowne nation." After Wolfe's death in 1576 this comprehensive plan was reduced to descriptions and histories of England, Scotland and Ireland. The historical section was to be supplied by Raphael Holinshed, the topographical by Harrison. The work was eventually published as *The Chronicles of England, Scotland and Ireland* . . . by Raphael Holinshed and others, and was printed in two black-letter folio volumes in 1577. Harrison's *Description of England*, humbly described as his "foule frizeled treatise," and dedicated to his patron Cobham, is an invaluable survey of the condition of England under Elizabeth, in all its political, religious and social aspects. He is properly contemptuous of the snobbery that was even then characteristic of English society; but his account of "how gentlemen are made in England" must be read in full to be appreciated. He is especially instructive on the condition and services of the church immediately after the Reformation; notably in the fact that, though an ardent Protestant, he is quite unconscious of any breach of continuity in the life and organization of the Church of England. Harrison also contributed the translation from Scots into English of Bellenden's version of Hector Boëce's Latin *Description of Scotland*.

For the later editions of the *Chronicles of England* . . . see HOLINSHED. The second and third books of Harrison's *Description* were edited by Dr. F. J. Furnivall for the New Shakspeare Society, with extracts from his "Chronologie" and from other contemporary writers, as *Shakspeare's England* (2 vols., 1877-78).

HARRISON, WILLIAM HENRY (1773-1841), ninth president of the United States, was born at Berkeley, Charles City county, Va., on Feb. 9, 1773, the third son of Benjamin Harrison (c. 1740-1791). His father was long prominent in Virginia politics and became a member of the Virginia house of burgesses in 1764; he was a member of the Continental Congress in 1774-

77, signing the Declaration of Independence and serving for a time as president of the board of war; speaker of the Virginia house of delegates in 1777-82; and governor of Virginia in 1781-84. William Henry Harrison received a classical education at Hampden-Sidney college, where he was a student in 1787-1790, and began a medical course in Philadelphia, but the death of his father caused him to discontinue his studies, and in Nov. 1791, he entered the army as ensign in the 10th Regiment at Fort Washington, Cincinnati. In the following year he became a lieutenant, and subsequently acted as aide-de-camp to Gen. Anthony Wayne in the campaign which ended in the battle of Fallen Timbers on Aug. 10, 1794. He was promoted to a captaincy in 1797 and for a brief period served as commander of Fort Washington, but resigned from the army in June 1798. Soon afterwards he was made secretary of the North-west Territory. In 1799 he was chosen by the Jeffersonian party of this territory as the delegate of the territory in Congress. While serving in this capacity he devised a plan for disposing of the public lands upon favourable terms to actual settlers, and also assisted in the division of the North-west Territory.

In Jan. 1800, President John Adams appointed him governor of the newly created Indiana Territory, which comprised until 1809 a much larger area than the present State of the same name. He was sworn into office on Jan. 10, 1801, and was governor until Sept. 1812. Among the legislative measures of his administration may be mentioned the attempted modification of the slavery clause of the ordinance of 1787 by means of an indenture law; more effective land laws; and legislation for the more equitable treatment of the Indians and for preventing the sale of liquor to them. In 1803 Harrison also became a special commissioner to treat with the Indians "on the subject of boundary or lands," and as such negotiated various treaties—at Fort Wayne (1803 and 1809), Vincennes (1804 and 1809) and Grouseland (1805)—by which the southern part of the present State of Indiana and portions of the present States of Illinois, Wisconsin and Missouri were opened to settlement. For a few months after the division in 1804 of the Louisiana Purchase into the Orleans Territory and the Louisiana Territory he also acted as governor of the Louisiana Territory.

The Indian cessions of 1809, along the Wabash river, aroused the hostility of Tecumseh (q.v.) and his brother, familiarly known as "The Prophet," who were attempting to combine the tribes between the Ohio and the Great Lakes in opposition to the encroachment of the whites. Several fruitless conferences between the governor and the Indian chiefs, who were believed to be encouraged by the British, resulted in Harrison's advance with a force of militia and regulars to the Tippecanoe river, where (near the present Lafayette, Ind.) on Nov. 7, 1811, he won over the Indians, a victory which established his military reputation and was largely responsible for his subsequent election to the presidency of the United States. From one point of view the battle of Tippecanoe may be regarded as the opening skirmish of the war of 1812. When in the summer of 1812 open hostilities with Great Britain began, Harrison was appointed major-general in the Kentucky militia. A few weeks later (Aug. 22, 1812) he was made brigadier-general in the regular U.S. army, and soon afterwards was put in command of all the troops in the north-west, and on March 2, 1813 he was promoted to the rank of major-general. General James Winchester, whom Harrison had ordered to prepare to cross Lake Erie on the ice and surprise Fort Malden, turned back to rescue the threatened American settlement at Frenchtown (now Monroe), on the Raisin river, and there on Jan. 22, 1813 was forced to surrender to Col. Henry A. Proctor. Harrison accomplished nothing that summer except to hold in check Proctor, who (May 1-5) besieged him at Fort Meigs, the American advanced post after the disaster of the river Raisin. After Lieut. O. H. Perry's naval victory, Sept. 10, 1813, Harrison no longer had to remain on the defensive; he advanced to Detroit, re-occupied the territory surrendered by Gen. William Hull, and on Oct. 5 administered a crushing defeat to Proctor at the battle of the Thames.

In 1814 Harrison resigned his commission. President Madison then utilized Harrison in negotiating with the north-western

Indians a second treaty of Greenville (July 22, 1814), by which they were to become active allies of the United States, should hostilities with Great Britain continue. This treaty publicly marked an American policy of alliance with these Indians. From 1816 to 1819 Harrison was a representative in Congress, and as such worked in behalf of more liberal pension laws and a better militia organization, including a system of general military education, of improvements in the navigation of the Ohio, and of relief for purchasers of public lands, and for the strict construction of the power of Congress over the Territories, particularly in regard to slavery. Harrison was a member of the Ohio senate in 1819-21, and was an unsuccessful candidate for the national House of Representatives in 1822, when his Missouri vote helped to cause his defeat, he was a presidential elector in 1824, supporting Henry Clay, and from 1825 to 1828 was a member of the U.S. Senate. In 1828 Harrison was appointed as the first minister of the United States to Colombia. He became, however, an early sacrifice to Jackson's spoils system, being recalled within less than a year. For some years after his return from Colombia he lived in retirement at North Bend, Ohio.

Early in 1835 Harrison began to be mentioned as a suitable presidential candidate, and later in the year he was nominated for the presidency at large public meetings in Pennsylvania, New York and Maryland. In the election of the following year he attracted a large part of the Whig and anti-Masonic vote of the middle and western states and led among the candidates opposing Van Buren, but received only 73 electoral votes while Van Buren received 170. His unexpected strength, due largely to his clear, if non-committal, political record, rendered him the most "available" candidate for the Whig party for the campaign of 1840, and he was nominated by the Whig convention at Harrisburg, Pa., in Dec., 1839, his most formidable opponent being Henry Clay. The convention adjourned without adopting any "platform" of principles, the party shrewdly deciding to make its campaign merely on the issue of whether the Van Buren administration should be continued in power and thus to take full advantage of the popular discontent with the administration, to which was attributed the responsibility for the panic of 1837 and the subsequent business depression. Largely to attract the votes of democratic malcontents the Whig convention nominated for the vice-presidency John Tyler, who had previously been identified with the Democratic party. The campaign was marked by the extraordinary enthusiasm exhibited by the Whigs. Because of his fame as a frontier hero, of the circumstance that a part of his home at North Bend, Ohio, had formerly been a log cabin and of the story that cider, not wine, was served on his table, Harrison was derisively called by his opponents the "log cabin and hard cider" candidate; the term was eagerly accepted by the Whigs in whose processions miniature log cabins were carried and at whose meetings hard cider was served, and the campaign itself has become known in history as the "log cabin and hard cider campaign." Harrison's canvass was conspicuous for the immense Whig processions and mass meetings, the numerous "stump" speeches (Harrison himself addressing many meetings), and the use of campaign songs of party insignia, and of campaign cries (such as "Tippecanoe and Tyler too"); and in the election he won by an overwhelming majority of 234 electoral votes to 60 cast for Van Buren.

President Harrison was inaugurated on March 4, 1841. He chose for his cabinet Daniel Webster as secretary of state, Thomas Ewing as secretary of the treasury, John Bell as secretary of war, George E. Badger as secretary of the navy, Francis Granger as postmaster-general, and John J. Crittenden as attorney-general. He survived his inauguration only one month, dying on April 4, 1841, and being succeeded by the vice-president, John Tyler. The immediate cause of his death was an attack of pneumonia, but the malady was aggravated by the excitement attending his sudden change in circumstances and the incessant demands of office seekers. After temporary interment at Washington, his body was removed to the tomb at North Bend, Ohio, where it now lies. A few of Harrison's public addresses survive, the most notable being *A Discourse on the Aborigines of the Ohio*. It has been said of him: "He was not a great man, but he had lived in a great time,

and he had been a leader in great things." He was the first territorial delegate in the Congress of the United States and was the author of the first step in the development of the country's later homestead policy; the first presidential candidate to be selected upon the ground of "expediency" alone; and the first president to die in office. In 1795 he married Anna Symmes (1775-1864), daughter of John Cleves Symmes. Their grandson, Benjamin Harrison, was the 23rd president of the United States.

BIBLIOGRAPHY.—In 1824 Moses Dawson published at Cincinnati the *Historical Narrative of the Civil and Military Services of Major-General William H. Harrison*. This is the source of all the subsequent "lives" that have appeared. There are several "campaign" biographies, including one by Richard Hildreth (1839) and one by Caleb Cushing (1840); and there is a good sketch in *Presidents of the United States* (1894), ed. J. G. Wilson. An excellent study of Harrison's career in Indiana appears in vol. 4 of the *Indiana Historical Society Publications*. See for a recent study Dorothy Burne Goebel, "William Henry Harrison," in *Indiana Historical Collections*, vol. xiv.; Biographical Series, vol. ii. (1926); also Beverly W. Bond; "William Henry Harrison in the War of 1812," in *Mississippi Valley Historical Review*, vol. xiii, p. 499-516 (1926-27).

HARRISON, a town of Hudson county, N.J., U.S.A., on the Passaic river, opposite Newark. It is served by the Erie, the Lackawanna and the Pennsylvania railways. The population was 15,721 in 1920 (33.7% foreign-born white) and was estimated locally at nearly 17,000 in 1928. Harrison is an integral part of the Newark industrial district. It has several miles of river-front, lined with factories, and the aggregate output of its manufacturing industries was valued at \$45,738,000 in 1928. The principal products are steel, roller bearings, elevators, wires, leather, pumps, metal toys, electric lamps, gas and cutlery. The town was settled before the end of the 17th century. In 1840 it was set off from Lodi and named after President William Henry Harrison; in 1873 it was incorporated. Harrison originally included what is now the town of Kearny.

HARRISONBURG, a city of north-western Virginia, U.S.A., in the beautiful Shenandoah valley, at an altitude of 1,300ft.; the county seat of Rockingham county. It is on the Lee highway, and is served by the Baltimore and Ohio, the Chesapeake Western and the Southern railways, and by motor-coach lines in every direction. The population was 5,875 in 1920 (86% native white) and was estimated locally at over 7,000 in 1928. It is the seat of a State teachers' college for women and in the centre of a rich farming region. Its manufactures are chiefly such as use agricultural products or contribute to their production, and include the largest poultry-fattening houses in the East and several hatcheries and incubators. Harrisonburg was established by an act of the legislature in 1780, and at first was called Rocktown, from the large out-crop of limestone. It was incorporated as a town in 1849 and became a city in 1916.

HARRIS TWEED, the description applied to all-wool tweed fabrics of coarse and open texture, but having a soft feel. They are produced in Lewis and other islands of the Outer Hebrides, off the north-west coast of Scotland. The true Harris tweeds are made by the cottars and crofters who employ the best grades of native blackface or Cheviot wool in the natural colours, and also dyed with the natural vegetable dyes. The fleece wool is scoured, combed and spun into worsted threads by the primitive distaff method of hand-spinning, and then woven on primitive hand-loom, in the crofters' homes. Hence, the term "homespun tweed," said to be a corruption of the Scottish word "tweel," and English "twill."

Harris homespun tweeds are distinguished for their great durability and a peculiar peaty odour, which is actually simulated in the many imitations of Harris tweeds produced by modern spinning and weaving machinery. The superiority of the home-made over the machine-made tweeds is said to be due to the use of long stapled wool in the homespun yarn, in addition to this being spun with a little more twist; whereas the machine-made Harris tweeds are sometimes produced from a mixture of wool and shoddy, which is spun with less twist in order to make a cheaper fabric. Very cheap and inferior imitations of Harris and Scotch tweeds are also produced from yarn spun from a mixture of both cotton and shoddy. (See TWEEDS.)

(H. N.)

HARRODSBURG, a city of Kentucky, U.S.A., 74 m. S.E. of Louisville, on the Southern railway; the county seat of Mercer county. The population was 3,765 in 1920 (26% negroes). There are sulphur springs here, and the city has been a health and summer resort since early in the 19th century. It is the trade centre for a rich region, producing especially fine trotting horses, white burley tobacco and poultry. Electric power is supplied from the Dix Dam hydro-electric plant. Harrodsburg is the oldest permanent settlement in the State, founded on June 16, 1774, by James Harrod. Daniel Boone helped in laying out the site, and from Ft. Harrod George Rogers Clark planned the conquest of the north-west. The city was chartered in 1875.

HARROGATE, a municipal borough of the West Riding of Yorkshire, England, 18 m. N. of Leeds, 19 m. W. of York, 203 m. N. by W. from London, on the L.N.E. railway. Pop. (1891), 16,316, (1901) 28,423, (1911) 33,703, (1921) 38,885. It stands about 400 ft. above sea-level, on the Pennine foothills, with Blubberhouses moor lying to the west, and the Vale of York to the east. It is thus an excellent tourist centre for the high moorland district and the dales of Yorkshire and is not far from the beauty spots of Fountains abbey, Bolton abbey, etc. Harrogate is the principal inland watering place in the north of England, containing upwards of 80 mineral springs for bathing and drinking purposes. It owes its rise and importance to the presence of these springs.

The town consists of two scattered townships—Low Harrogate, sheltered and warm in winter, and High Harrogate, with a more bracing climate. These have gradually been connected by the growth of villas extending from both the high and the low town. A common, called the Stray, secured by act of parliament from ever being built upon, stretches for 200 ac. in front of the main lines of houses, and so, notwithstanding its rapid growth, Harrogate has retained much of its rural charm.

The principal chalybeate springs are the Tewitt well, discovered towards the close of the 16th century by Captain William Slingsby, of Bilton Hall, and called "The English Spa" by Dr. Bright, who wrote the first account of it; the Royal Chalybeate Spa, more commonly known as John's Well, discovered by Dr. Stanhope, of York, in 1631; Muspratt's chalybeate or chloride of iron spring, discovered in 1819, but first properly analysed by Dr. Sheridan Muspratt in 1865; and the Starbeck springs, midway between High Harrogate and Knaresborough. The chief sulphur springs are the old sulphur well in the centre of Low Harrogate, discovered about the year 1656; the Montpellier springs, the principal well of which was discovered in 1822, situated in the grounds of the Crown hotel, and the Harlow Car springs, in a wooded glen about 1 m. W. from Low Harrogate. A saline spring was discovered in Low Harrogate in 1783. The principal bath establishments are the Victoria Baths (1871) and the Royal Baths (1897), both of which are owned by the corporation. Harrogate also contains a handsome Kursaal, opened in 1903, a grand opera house, numerous modern churches, and several hospitals, including the Royal Bath hospital. Harlow Hill observatory, a square tower 100 ft. in height, stands on elevated ground about 1 m. W. of Low Harrogate, and commands a very extensive view. The town was incorporated in 1884, the corporation consisting of a mayor, eight aldermen and 24 councillors.

HARROW: see CULTIVATING MACHINERY.

HARROWBY, DUDLEY RYDER, 1ST EARL OF (1762–1847), the eldest son of Nathaniel Ryder, 1st Baron Harrowby (1735–1803), was born in London on Dec. 22, 1762, and educated at St. John's college, Cambridge. He entered parliament in 1784, and held various offices in administrations from 1789 onwards. In 1804 he was secretary of State for foreign affairs and in 1805 chancellor of the duchy of Lancaster under his intimate friend William Pitt; in 1805 he was sent on a mission to the emperors of Austria and Russia and the king of Prussia, and for the long period between 1812 and 1827 he was lord president of the council. After Canning's death in 1827 he refused the premiership, and never held office again. He died at Sandon Hall, Staffs, on Dec. 26, 1847, being, as Charles Greville says, "the last of his generation and of the colleagues of Mr. Pitt, the sole survivor

of those stirring times and mighty contests."

HARROW FOOTBALL: see FOOTBALL: *the Harrow Game*.

HARROWING OF HELL, an English poem in dialogue, dating from the end of the 13th century. It is written in the East Midland dialect, and is generally cited as the earliest dramatic work in the language, though it was probably intended for recitation rather than performance. The opening words—"Alle herkeneth to me nou A strif wille I tellen ou Of Jesu and of Satan"—seem to indicate that the piece was delivered by a single performer. The subject—the descent of Christ into Hades to succour the souls of the just, as related in the apocryphal gospel of Nicodemus,—is introduced in a kind of prologue; then follows the dispute between "Dominus" and "Satan" at the gate of Hell; the gatekeeper runs away, and the just are set free, while Adam, Eve, Habraham, David, Johannes and Moyses do homage to the deliverer. The poem ends with a short prayer: "God, for his moder loue Let ous never thider come." Metrically, the poem is characterized by frequent alliteration imposed upon the rhymed octosyllabic couplet:—

Welcome, loured, god of londre

Godes sone and godes sonde (ii. 149–150).

The piece is obviously connected with the Easter cycle of liturgical drama, and the subject is treated in the York and Townley plays.

Mss. are: Brit. Mus., Harl. ms. 2,253; Edinburgh, Auchinleck ms., W 41; Oxford, Bodleian, Digby 86. It was privately printed by J. P. Collier and by J. O. Halliwell, but is available in Appendix iii. of A. W. Pollard's *English Miracle Plays* . . . (4th ed., 1904); K. Bøddeker, *Altengl. Dichtungen des MS. Harl. 2,253* (1878); and E. Mall, *The Harrowing of Hell* (Breslau, 1871). See also Sir E. K. Chambers, *The Mediaeval Stage* (1903).

HARROW-ON-THE-HILL, urban district, Middlesex, England, 12 m. W.N.W. of St. Paul's cathedral, London, served by the L.M.S., Metropolitan and District railways. Pop. (1921) 19,469. It takes its name from its position on an isolated hill rising to a height of 345 ft. On the summit is the church of St. Mary, said to have been founded by Lanfranc, archbishop of Canterbury, and Norman work appears at the base of the tower.

Harrow school was founded in 1571 by John Lyon, whose brass is in the church, a yeoman of the neighbouring village of Preston who had yearly during his life set aside 20 marks for the education of poor children of Harrow; though a school existed before his time. Though the charter was granted by Queen Elizabeth in 1571, and the statutes drawn up by the founder in 1590, two years before his death, it was not till 1611 that the first building was opened for scholars. Lyon settled about two-thirds of his property on the school. About 1660 the headmaster, taking advantage of a concession in Lyon's statutes, began to receive "foreigners," i.e., boys from other parishes, who were to pay for their education. From this time the prosperity of the school may be dated. In 1809 the parishioners of Harrow appealed to the court of chancery against the manner in which the school was conducted, but the decision, while it recognized their privileges, confirmed the right of admission to foreigners. Control was originally vested in six persons of standing in the parish who had the power of filling vacancies in their number by election among themselves; but under the Public Schools act of 1868 the governing body consists of six members who are elected respectively by the lord chancellor, the universities of Oxford, Cambridge and London, the Royal Society and the assistant masters of the school. Harrow was originally an exclusively classical school, but is such no longer. The principal buildings are modern. The fourth form room, however, dates from 1611, and on its panels are cut the names of many eminent *alumni*, such as Byron, Robert Peel, R. B. Sheridan and Temple (Lord Palmerston).

A considerable extension of Harrow as an outer residential suburb of London has taken place north of the hill, where is the urban district of Wealdstone (pop. [1925] 13,433), and there are also important printing and photographic works.

HARRY THE MINSTREL or **BLIND HARRY** (fl. 1470–1492), author of the Scots historical poem *The Actis and Deidis of the Illustere and Vailzeand Campioun Schir William*

Wallace, *Knight of Ellerslie*, flourished in the latter half of the 15th century. He appears to have been a blind Lothian man, in humble circumstances, who had some reputation as a storyteller; he received, on five occasions, in 1490 and 1491, gifts from James IV. He is alluded to by Dunbar (*q.v.*) in the fragmentary *Interlude of the Droichis Part o' the Play*, where a "droich," or dwarf, personates

"the nakit blynd Harry
That lang has bene in the fary
Farleis to find";

and again in Dunbar's *Lament for the Makaris*. John Major (*q.v.*) in his Latin *History* says that Henry used to recite his tales before nobles, and thus received food and clothing as his reward (Bk. iv., ch. xv.).

The poem (preserved in a unique ms., dated 1488, in the Advocates' library, Edinburgh) is divided into 11 books and runs to 11,853 lines. It is one of the earliest, certainly one of the most extensive, verse-documents in Scots written in five-accent, or heroic, couplets. It is also the earliest outstanding work which discloses that habit of Scotticism which took such strong hold of the popular Northern literature during the coming years of conflict with England. But there are elements in the poem which show that it is not entirely the work of a poor crowder; and these (notably references to historical and literary authorities, and occasional reminiscences of the literary tricks of the Scots Chaucerian school) have inclined some to the view that the text, as we have it, is an edited version of the minstrel's rough song-story. It has been argued, though by no means conclusively, that the "editor" was John Ramsay, the scribe of the Edinburgh ms. and of the companion Edinburgh ms. of the *Brus* by John Barbour (*q.v.*).

The poem appears, on the authority of Laing, to have been printed at the press of Chepman and Myllar about 1508, but the fragments which Laing saw are not extant. The first complete edition, now available, was printed by Lekprevik for Henry Charteris in 1570 (Brit. Museum). There are many reprints, including some of William Hamilton of Gilbertfield's modern Scots version of 1722. The first critical edition was prepared by Dr. Jamieson and published in 1820. In 1889 the Scottish Text Society completed their edition of the text, with prolegomena and notes by James Moir.

HARSDÖRFFER, GEORG PHILIPP (1607-1658), German poet, was born at Nuremberg on Nov. 1, 1607. Jointly with Johann Klaj he founded in 1644 at Nuremberg the literary society of the Pegnitzschäfer, for the purification of the German language. He died at Nuremberg on Sept. 22, 1658. His writings in German and Latin fill 50 volumes, and a selection of his poems, interesting mostly for their form, is to be found in Müller's *Bibliothek deutscher Dichter des 17ten Jahrhunderts*, vol. ix. (Leipzig, 1826).

His life was written by Widmann (Altdorf, 1707). See also Tittmann, *Die Nürnberger Dichterschule* (Göttingen, 1847), and Krapp, *Die ästhetischen Tendenzen Harsdörffers* (1904).

HARSHA or **HARSHAVARDHANA** (fl. A.D. 606-648), an Indian king who ruled northern India as paramount monarch for over forty years. The events of his reign are related by Hsüan Tsang, the Chinese pilgrim, and by Bana, a Brahman author. He was the son of a raja of Thanesar, who waged successful wars against the Huns and came to the throne in A.D. 606, though he was only crowned in 612. He devoted himself to a scheme of conquering the whole of India, and carried on wars for thirty years with success, until (A.D. 620) he came in contact with Pulakesin II., the greatest of the Chalukya dynasty, who made himself lord of the south, as Harsha was lord of the north. The Nerbudda river formed the boundary between the two empires. In the latter years of his reign Harsha's sway over the whole basin of the Ganges from the Himalayas to the Nerbudda was undisputed. After thirty-seven years of war he set himself to emulate Asoka and became a patron of art and literature. He was the last native monarch who held paramount power in the north prior to the Mohammedan conquest; and was succeeded by an era of petty states.

See Bana, *Sri-harsha-charita*, trans. Cowell and Thomas (1897); Ettinghausen, *Harsha Vardhana* (Louvain, 1906).

HART, ALBERT BUSHNELL (1854-), American historian, was born at Clarksville (Penn.), on July 1, 1854. He graduated from Harvard College in 1880, and studied at Paris, Berlin and Freiburg. He was instructor in history at Harvard in 1883-87, assistant professor in 1887-97, and professor in 1897-1910, and professor of government 1910-1926. Among his writings are: *Practical Essays on American Government* (1893); *Studies in American Education* (1895); *Guide to the Study of American History* (with Edward Channing, 1897, and with Edward Channing and F. J. Turner, 1912); *Salmon Portland Chase* (1899); *Foundations of American Foreign Policy* (1901); *Actual Government* (1903); *Slavery and Abolition* (1906) and *National Ideals Historically Traced* (1907), both in the "American Nation" series, which he edited (1904 to 1918); *Monroe Doctrine* (1916); *We and Our History* (1923); *Formation of the Union*, which brought him recognition in 1892, was re-issued in 1925.

In addition he edited *American History told by Contemporaries* (1897-1929), *Source Readers in American History* (1901-03), and other series; and was editor of the *American Year Book*. He served as president of the American Historical Association in 1909 and of the American Political Science Association in 1912.

HART, CHARLES (d. 1683), English actor, grandson of Shakespeare's sister Joan, is first heard of as playing women's parts at Blackfriar's theatre as an apprentice of Richard Robinson. In the Civil War he was a lieutenant of horse in Prince Rupert's regiment, and after the king's defeat he played surreptitiously at the Cockpit and at Holland House and other noblemen's residences. After the Restoration he is known to have been in 1660 the original Dorante in *The Mistaken Beauty*, adapted from Corneille's *Le Menteur*. In 1663 he went to the Theatre Royal in Killigrew's company, with which he remained until 1682, taking leading parts in Dryden's, Jonson's and Beaumont and Fletcher's plays. He is highly spoken of by contemporaries in such Shakespearian parts as Othello and Brutus. He is often mentioned by Pepys. Betterton praised him, and would not himself play the part of Hotspur until after Hart's retirement. Hart is said to have been the first lover of Nell Gwyn, and to have trained her for the stage.

HART, ERNEST ABRAHAM (1835-1898), English medical journalist, was born in London on June 26, 1835, the son of a Jewish dentist. Beginning on the *Lancet* in 1857, he was made editor of the *British Medical Journal* in 1866. He took a leading part in the exposures which led to the reform of the treatment of sick poor throughout England, and the Infant Life Protection act of 1872, aimed at the evils of baby-farming, was largely due to his efforts. The record of his public work covers nearly the whole field of sanitary legislation during the last 30 years of his life: the amendments of the Public Health and of the Medical acts, the measures relating to notification of infectious disease and to vaccination, and the improvement of factory legislation, etc. From 1872 to 1897 he was chairman of the parliamentary bill committee of the British Medical Association. He died on Jan. 7, 1898.

HART, SIR ROBERT, 1ST BART., CR. 1893 (1835-1911), Irish-Chinese statesman, was born at Portadown, Co. Armagh, on Feb. 20, 1835. He was educated at Taunton, Dublin and Belfast, and graduated at Queen's College, Belfast, in 1853. In the following year he received an appointment as student-interpreter in the China consular service, and after serving for a short time at the Ningpo vice-consulate, he was transferred to Canton, where after acting as secretary to the allied commissioners governing the city, he was appointed the local inspector of customs. There he first gained an insight into custom-house work. One effect of the Tai-ping rebellion was to close the native custom-house at Shanghai; and it was arranged by Sir Rutherford Alcock, the British consul, with his French and American colleagues, that they should undertake to collect the duties on goods owned by foreigners entering and leaving the port. Sir T. Wade was appointed to the post of collector in the first instance, and after a short tenure of office was succeeded by Mr. H. N. Lay, who held the post until 1863. The

system adopted at Shanghai was applied to the other treaty ports, so that when on Lay's resignation Hart was appointed inspector-general of foreign customs, the organization collected a revenue of upwards of eight million taels per annum at fourteen treaty ports. During Hart's tenure of the office the revenue of the department grew from upwards of eight million taels to nearly twenty-seven million, collected at the thirty-two treaty ports, and the customs staff, which in 1864 numbered 200, reached in 1901 a total of 5,134. From the first Hart gained the entire confidence of the Chinese government; of all their numerous sources of revenue, the money furnished by Hart was the only certain asset which could be offered as security for Chinese loans. The British minister, as well as the ministers of other powers, constantly consulted him, and in 1885 Granville gazetted him British minister plenipotentiary at Peking, which appointment he did not take up. His confidence in the Chinese made him turn a deaf ear to the warnings which he received of the threatening Boxer movement in 1900. To the last he believed that the attacking force would at least have spared his house, which contained official records of priceless value, but he was mistaken. The building was burnt to the ground with all that it contained, excepting his private diary for forty years. When the stress came, and he retreated to the British legation, he took an active part in all the measures for the defence. Hart established a postal service in connection with the customs, which gradually developed into the regular postal service of China of which he was Inspector-General.

The appointment of Sir Robert Hart as Inspector-General of the imperial maritime customs secured the interests of European investors in Chinese securities, and helped to place Chinese finance generally on a solid footing. When, therefore, in May 1906 the Chinese government appointed a Chinese administrator and assistant administrator of the entire customs of China, who would control Sir Robert Hart and his staff, great anxiety was aroused. Hart obtained formal leave of absence of two years and returned to Europe in the spring of 1908, when he received the title of president of the board of customs. At the end of this period he tendered his resignation to the Chinese Government who refused to accept it and extended his leave. He died, whilst still on leave, on September 20, 1911, at Great Marlow, Bucks. Sir Robert married in 1866, Hester, daughter of Alexander Bredon of Portadown.

See Juliet Bredon, *Sir Robert Hart* (1909).

HARTE, FRANCIS BRET (1839-1902), American author, was born in Albany, N.Y., on Aug. 25, 1836, of English and Dutch parentage. His grandfather on his father's side was a Jew. His father, a school teacher, and his mother gave him a rich intellectual and literary background, and their library gave him every opportunity to read widely and well. Ill health from six to ten kept the young lad from engaging in games with other children and he spent those years reading Shakespeare, Froissart, Dickens, Fielding, Washington Irving and others. At the age of 11 he wrote a poem, "Autumnal Musings," which was published in the *New York Sunday Atlas*. His family discouraged further poems, and while he continued to write them he made no attempt to have them published at the time. Later he was amply repaid for his patience.

Owing to family financial straits, Bret Harte left school when only 13, spent about a year in a lawyer's office and then went to the counting room of a merchant. He was supporting himself by the time he was 16. Three years later he joined his mother who had gone to California. For a time he taught in a school, clerked for an apothecary, tutored and was an express messenger on a California stage, but was also writing stories and poems for magazines. Later he became a printer for the *Humboldt Times* (Calif.), and then assistant editor of the *Northern California*, the latter work being cut short by a scathing editorial, written in his chief's absence on the massacre of Indians by Americans, which aroused the antagonism of the community. But his varied experiences and continued journeyings furnished inspiration and material for his frontier tales.

In 1857 Bret Harte became a typesetter for the *Golden Era*

in San Francisco. Here he so interested the editor that he was given an opportunity to contribute some short sketches and later worked in the editorial room. In 1864 he procured a position as secretary of the California Mint which gave him more time for his writing. He wrote a series of *Condensed Novels*, parodies of well known fiction, for *The Californian*, to which Mark Twain was also contributing. A year later his book of poems, *The Lost Galleon*, appeared. In 1868 he was made editor of the *Overland Monthly*. *The Luck of Roaring Camp*, which he wrote for this magazine, attracted the attention of editors in the East and brought requests for his vivid western tales. He was also made a professor of recent literature at the University of California, which work he continued for two years with his editorship of *The Overland* and his work at the Mint. Then his verses, "The Heathen Chinee," brought such urgent demands from the East to return that he went to New York in 1871.

Bret Harte was lionized by the whole country and "hailed as a new prophet in American letters." His trip East, so like a triumphal march, caught the attention of foreign papers and his stories were reprinted and translated abroad. For a time he was in great demand as a lecturer on his Californian experiences and he continued writing his stories of pioneer life. Unfortunately, however, his income did not provide for the extravagant living he insisted on and he became involved in financial difficulties. His friends were instrumental in having him appointed as U.S. commercial agent at Crefeld in Germany. Reluctantly and yet with mingled relief and hope of re-establishing himself he left America, never to return.

He was most cordially welcomed in literary circles in London where he spent much of his time, writing and lecturing. He was never happy about his work in Crefeld, and in 1880 was appointed consul to Glasgow. During the five years in this office he wrote a large number of stories for American magazines and attempted several plays which, however, proved unsuccessful. From 1885 until his death on May 5, 1902, in Camberley, England, Bret Harte lived in London.

It is doubtful if Bret Harte ever surpassed the work of his early stories *The Luck of Roaring Camp*, *The Outcasts of Poker Flat* and *Tennessee's Partner*, yet he did reach the high level of these masterpieces in *The Twins of Table Mountain*, *The Ancestors of Peter Atherley* and *Left Out on Lone Star Mountain*. His outstanding poem was "The Heathen Chinee."

BIBLIOGRAPHY.—*Works* (20 vols., 1904); *Letters of Bret Harte* (1926); H. C. Merwin, *Life of Bret Harte* (1911); J. Erskine, "Bret Harte," in *Leading American Novelists* (1910); L. L. Hazard, *The Frontier in American Literature* (1927).

HARTEBEEST (hahr'tā-bāst), a large South African antelope, *Bubalis cama*, characterized by its red colour, long face with naked muzzle, and sharply angulated lyrate horns, present in both sexes. This graceful animal, one of the swiftest of African antelopes, easily outdistancing greyhounds, formerly occurred in great herds from Cape Colony to Rhodesia, but is now comparatively rare and restricted to remote districts. It stands about 4 ft. high at the withers, with heavy forequarters, which are much higher than the narrow and drooping hindquarters. The name is sometimes extended to include all members of the genus. (See ANTELOPE.)

HARTFORD, capital of Connecticut, U.S.A., at the head of navigation on the Connecticut river, 38 m. from Long Island sound and 100 m. N.E. of New York city; a port of entry and the county seat of Hartford county. It is served by the New York, New Haven and Hartford railroad, by steamers to New York and by numerous motor bus and freight truck lines operating over the federal and state highways which radiate in every direction; and is a station on the air-mail route from Boston to New York and the west and south. The population in 1920 was 138,036, of whom 40,667 were foreign-born white (over half from Russia, Poland, Italy and Ireland); and was estimated locally at 178,000 in 1928. The city covers 18 sq.m. of undulating ground on the west bank of the river, surrounded by the beautiful valley and gently rolling hills. From the north-west and the south-west corners enter the two branches of the little Park river, which unite about the middle of the city, after many twists and turns, and meander on to the

Connecticut. A fine stone bridge of nine arches, dedicated in 1908, spans the Connecticut, commanding a panorama of city and river. The city is well laid out and compactly built, with many distinctive features. Since 1907 development has been guided by a city-plan commission. The State capitol stands on a hill in Bushnell park, in the heart of the city. It is a handsome building of white marble, designed by Richard M. Upjohn, and was completed (1878) at a cost (\$2,642,524) within the original appropriations. It contains many objects of historic interest, including the tombstone of Israel Putnam and a carved chair made for the senate chamber from the wood of the charter oak (*see below*). In the park is the Corning memorial fountain (1899), designed by J. Massey Rhind, and the memorial arch and bridge (across the Park river) erected by the city in 1884 in tribute to the soldiers and sailors of the Civil War. Facing the capitol on the south is the supreme court and State library building (1910), and across the west lawn is the State armory and arsenal, one of the largest in the country. Between the capitol and the Connecticut river stands the old three-story brick State house (1796), a gem of colonial architecture, designed by Charles Bulfinch. When the new capitol was occupied it was turned over to the city, and for a generation was used as a city hall, but since 1915 it has been restored as an historic shrine. Near by is the First Church of Christ (Congregational), known as the Center church, which was organized in Cambridge, Massachusetts, in 1632, and moved to Hartford in 1636 under the leadership of Thomas Hooker and Samuel Stone. The present building (1807) stands near the site of the original meeting-house, and adjoins the graveyard where Hooker, William Leete, John Haynes and their contemporaries were buried. Across the street, a little to the south, is a group of museum and library buildings: the Wadsworth atheneum (built in 1844 by popular subscription, and more recently enlarged and heavily endowed), containing historical treasures; the Colt memorial (1908) housing the collection of fire-arms gathered by Col. Samuel Colt, the Hartford armourer; and the Junius Spencer Morgan memorial, an art gallery built (1908) by J. Pierpont Morgan in memory of his father, a native of Hartford.

There are 25 parks and public squares, covering 1,340 ac. (11.6% of the city's area) and containing golf links, tennis courts, 65 baseball diamonds and one of the finest rose gardens in the country. Two miles south of the centre of the city is the municipal airport (Brainard field), 165 ac. of grass-covered river silt. A bond issue of \$1,000,000 was approved by the voters in 1928 for a dike and other flood-control works to protect the landing field and the rest of the south meadows. Among the business buildings the homes of the insurance companies, many of them architecturally beautiful, are as conspicuous as their business is important in the economic life of the city. The tower of the Travellers companies (527 ft. high, the highest building in New England) is a landmark for aviators and others, visible for many miles, by day and by night.

Hartford is the seat of Trinity college (chartered as Washington college in 1823); the Hartford Theological seminary (Congregational), founded at East Windsor Hill in 1834 and moved to Hartford in 1865, and associated with it the School of Religious education and the Kennedy school of missions; St. Thomas's seminary (Roman Catholic) and a Roman Catholic cathedral; the Hartford retreat for the insane (opened 1824); and the State school for the blind. The American School for the Deaf, founded in Hartford by Thomas W. Gallaudet in 1816, the first in America, is now in the adjoining town of West Hartford. The public-school system includes 25 elementary, 3 high, and one trade school, and the city's appropriations for education, including the public library, was \$3,320,531 for the fiscal year 1928-29. The *Hartford Times* (est. 1817) has a beautiful building and notable mechanical equipment; and the *Courant* (est. 1764) is the oldest newspaper in America.

Insurance is Hartford's outstanding business, employing 16,000 men and women in the local offices. The 43 companies (fire, life and casualty) which have their home offices here had a total premium income in 1927 of \$569,712,171, and have paid to policyholders and beneficiaries since their organization \$3,766,571,483.

Manufacturing also is important. The 337 industrial establishments in 1927 had an output valued at \$113,674,982, and their annual payroll approximates \$32,000,000. Among the widely distributed articles made in Hartford are small fire-arms, typewriters, brushes, precision machines and small tools. Other important manufactures are silver plate, hardware, rubber tires, electric equipment and aeroplanes. Hartford is a trading centre for a population of 450,000, and the market for the agricultural products of the county, including tobacco to the value of \$15,000,000 annually. Bank debits in 1927 amounted to \$2,237,553,092.

History.—The first settlement here was made by Dutch from New Amsterdam, who in 1633 built a fort at the mouth of Park river, which they held until 1654. In 1635, 60 English settlers came from New Town (now Cambridge), Massachusetts, and in 1636 practically all the rest of the New Town congregation joined them, led by Thomas Hooker and Samuel Stone. Their settlement was at first called Newtown, but in 1637 the present name was adopted, from Hertford, the birthplace of Stone. The first general court of the Connecticut colony was held here in 1636, and its first written constitution (the Fundamental Orders) was adopted here in 1639. When the colonies of New Haven and Connecticut were united (1662) Hartford became the capital, but shared the honour with New Haven from 1701 to 1873. In 1687 Governor Andros came to Hartford to take away the royal charter of 1662, under which the colonists practically had local sovereignty. At his meeting with the officials of the colony, when the document was on the table, suddenly the candles were blown out, and when they were re-lighted the charter had disappeared. It was hidden by Capt. Joseph Wadsworth in a hollow tree ("the Charter Oak") the site of which is now marked by a granite monument. The city was chartered in 1784, and in 1881 was made co-extensive with the town of Hartford.

In the latter part of the 18th century Hartford was the home of a group of Federalist authors known as "the Hartford Wits," including Lemuel Hopkins, John Trumbull, Joel Barlow and David Humphreys; and in 1814-15 it was the meeting-place of the Hartford Convention, an event of great importance in the history of the Federalist party. Delegates from Massachusetts, Connecticut, Rhode Island, New Hampshire and Vermont met in secret session from Dec. 15, 1814, to Jan. 5, 1815, to consider the grievances of New England against the national (Democratic) government in its conduct of the war with Great Britain. The convention recommended a greater measure of military control for the several States, and proposed (for consideration by the State legislatures) a number of amendments to the federal constitution, limiting the power of Congress and of the executive. The legislatures of Massachusetts and Connecticut were the only ones which approved the proposed amendments. They sent commissioners to Washington to urge their adoption, but before they arrived the war had come to an end. Nine state legislatures expressed positive disapproval of the convention, some charging it with sowing "seeds of dissension and disunion," and in general it was vigorously criticized throughout the country.

During the 18th century Hartford had a large and lucrative commerce, but with the development of railways in the 19th century it suffered from the competition of Boston and New York. The first woollen mill in New England was established here in 1788, and here about 1846 the Rogers process of electro-silver plating was invented. As early as 1794 policies were issued by the Hartford Fire Insurance company (chartered in 1810). In the San Francisco disaster of 1906 the fire insurance companies of Hartford paid more than \$15,000,000 in losses. Hartford was the birthplace of Noah Webster, who published here (1783-85) his *Grammatical Institute of the English Language*, and of Henry Barnard, John Fiske and Frederick Law Olmsted. It was the home of Samuel P. Goodrich (Peter Parley), George D. Prentice, Harriet Beecher Stowe, Charles Dudley Warner, Horace Bushnell and Samuel L. Clemens (Mark Twain). More than 100 periodicals have been established in Hartford. The *Congregationalist* (now published in Boston) and the *Churchman* (now published in New York) were founded in Hartford in 1816 and 1805 respectively. The *Hartford Courant* was very influential in shaping public opin-

ion in the years preceding the Revolution, and the *Times* (edited by Gideon Wells 1826-36) was one of the most powerful Democratic organs in the second quarter of the 19th century.

See *Scaeva, Hartford in the Olden Times: Its First Thirty Years* (1853); J. H. Trumbull, *Memorial History of Hartford County* (1886); *History of the Hartford Convention* (1833); H. C. Lodge, *Life and Letters of George Cabot* (1877); Henry Adams, *Documents Relating to New England Federalism* (1877).

HARTFORD, a city of Washington county, Wisconsin, U.S.A., 37 m. N.W. of Milwaukee, on the Chicago, Milwaukee, St. Paul and Pacific railroad. The population was 4,515 in 1920. It has large automobile works and various other manufacturing industries. It was founded c. 1850 and incorporated in 1884.

HARTFORD CITY, the county seat of Blackford county, Ind., U.S.A., 62 m. N.E. of Indianapolis. It is served by the Nickel Plate and the Pennsylvania railways and inter-urban electric lines. The population was 6,183 in 1920 (97% native white) and estimated locally at 7,500 in 1928. The city has important window-glass and chipped-glass factories, paper-pulp mills and other industries. It was settled in 1832, laid out in 1839, incorporated as a town in 1867 and as a city in 1894.

HARTIG, GEORG LUDWIG (1764-1837), German agriculturist and writer on forestry, was born at Gladenbach, near Marburg, on Sept. 2, 1764. After obtaining a practical knowledge of forestry at Harzburg, he studied from 1781 to 1783 at the University of Giessen. He held forestry appointments under various German princes, and established a school of forestry which he removed to Berlin in 1811. He secured its affiliation with the university. He died in Berlin on Feb. 2, 1837.

G. L. Hartig's works include *Lehrbuch für Förster* (3 vols., Stuttgart, 1808); *Lehrbuch für Jäger* (Stuttgart, 1810); *Kubiktabellen für geschnittene, beschlagene, und runde Hölzer* (1815, 10th ed. Berlin, 1871); and *Lexikon für Jäger und Jagdfreunde* (1836, 2nd ed. Berlin, 1859-61).

HARTLEPOOL, a parliamentary borough of Durham, England, embracing the municipal borough of Hartlepool or East Hartlepool and the municipal and county borough of West Hartlepool. Pop. (1921) of Hartlepool, 20,997; of West Hartlepool, 68,641. The towns are on the coast of the North sea separated by Hartlepool bay, with a harbour, and both have stations on the L.N.E. railway, 247 m. N. from London. The surrounding country is bleak, and the coast is low. The ancient market town of Hartlepool lies on a peninsula which at the end of a sweep of the coast, embraces the bay. Its naturally strong position was formerly fortified, and part of the walls, serving as a promenade, remain. The parish church of St. Hilda, is late Norman and Early English, with a massive tower, heavily buttressed. There is a borough hall in Italian style. The municipal area embraces the three townships of Seaton Carew, a seaside resort; Stranton, with its church of All Saints, of the 14th century, on a very early site; and Throston.

The two Hartlepoons are officially considered as one port. The harbour, which embraces two tidal basins and six docks aggregating 200 acres, included in which are timber docks (57 acres), with excellent facilities for storing timber. There are five graving docks, admitting vessels of 550 ft. length and 10 to 21 ft. draught. The depth of water on the dock sills varies from 16½ ft. at neap tides to 25 ft. at spring tides. A breakwater three-quarters of a mile long protects the entrance to the harbour. An important trade is carried on in the export of coal, ships, machinery, iron and other metallic ores, woollens and cottons, and in the import of timber, sugar, iron and copper ores, and eggs. The principal industries are shipbuilding (iron), boiler and engineering works, iron and brass foundries, steam saw and planing mills, flour-mills, paper and paint factories, and soapworks. The parliamentary borough returns one member.

Hartlepool (Hertepull, Hertipol) grew up round the monastery (founded 640), was destroyed by the Danes (800) and rebuilt by Egred, bishop of Lindisfarne. Bishop Hugh de Puiset (1173) allowed French and Flemish troops to land at Hartlepool to aid the Scots. It became the property of the see of Durham in 1189, and in 1201 received a charter from the bishop. Other charters were granted in 1230, in 1328 by Edward III., in 1397 by Richard II., and minor ones followed until Elizabeth incorporated the

borough in 1593. During the civil wars Hartlepool was taken by the Scots and garrisoned by them until 1647. As a borough of the Palatinate, Hartlepool did not receive parliamentary representation until the 19th century. In 1216 John confirmed the market on Wednesday and the fair on the feast of St. Lawrence; this fair was extended to fifteen days by the grant of 1230, while the charter of 1595 also granted a fair and market. During the 14th century trade was carried on with Germany, Spain and Holland, and in 1346 Hartlepool provided five ships for the French war. The markets were still considerable in Camden's day, but declined during the 18th century, when Hartlepool became fashionable as a watering-place.

HARTLEY, SIR CHARLES AUGUSTUS (1825-1915), English engineer, was born in 1825 at Heworth, Durham. From 1856 to 1872 he was engineer-in-chief for the works carried out by the European Commission of the Danube for improving the navigation at the mouths of that river, and from 1872 onwards he was consulting engineer to the Commission (see DANUBE). In 1875 he was a member of the committee appointed by Congress to report on the works necessary to form and maintain a deep channel through the south pass of the Mississippi delta; and in 1884 the British Government nominated him a member of the international technical commission for widening the Suez Canal. He was consulted by the British and other Governments in connection with many other river and harbour works, including the improvement of the navigation of the Scheldt, Hugli, Don and Dnieper, and of the ports of Odessa, Trieste, Kustendjie, Burgas, Varna and Durban. He was knighted in 1862, and became K.C.M.G. in 1884. He died in London on Feb. 20, 1915.

HARTLEY, DAVID (1705-1757), English philosopher, and founder of the Associationist school of psychologists, was born on Aug. 30, 1705. He was educated at Bradford grammar school and Jesus College, Cambridge, later practising as a physician at Newark, Bury St. Edmunds, London, and lastly at Bath, where he died on Aug. 28, 1757.

Hartley's *Observations on Man* was the first systematic attempt to interpret the phenomena of mind by the theory of association; its two main theories are the doctrine of vibrations and the doctrine of associations. His physical theory, he tells us, was drawn from Newton's *Principia*. His psychological theory was suggested by the Rev. John Gray's *Dissertation concerning the Fundamental Principles of Virtue or Morality*, which was prefixed to Bishop Law's translation of Archbishop King's *Origin of Evil*.

With Locke, Hartley asserted that, prior to sensation, the mind is a blank. From simple sensations, however, originate all states of consciousness, the law of growth being the law of contiguity, synchronous and successive. By this law he explained not only memory, as others had done, but also emotion (which he analyses with skill), reasoning, and voluntary and involuntary action (see ASSOCIATION OF IDEAS). He held that sensation is the result of a vibration of the minute particles of the medullary substance of the nerves made possible by Newton's subtle elastic ether.

BIBLIOGRAPHY.—The 1801 ed. of the *Observations* contains a life by his son. See also Sir L. Stephen, *Hist. of Eng. Thought in the 18th Century*; G. S. Bower, *Hartley and James Mill* (1881); B. Schönlanck, *Hartley und Priestley die Begründer des Assoziationismus in England* (1882); Th. Ribot, *English Psychology* (Eng. trs., 1873); E. Albee, *Hist. of Eng. Utilitarianism* (1902).

HARTLEY, DAVID, the younger (1731-1813), parliamentarian, pamphleteer and inventor, the son of the above, was a fellow of Merton college, Oxford, and member of Parliament for Hull (Kingston-upon-Hull) from 1774-80 and from 1782-84. He gained fame about 1776 by a discovery intended to protect buildings against fire, and attracted important gatherings to his experiment-house on Putney Common, where an obelisk stands in his honour. He was the friend and correspondent of Benjamin Franklin, with whom he had many interests; and he gave up the greater part of his political career to opposing the American War, speaking frequently and at length in the Commons, and publishing in 1778 his vigorous *Letters on the American War*. He was appointed by the Fox-North ministry as a plenipotentiary to treat with the Americans in 1783, and signed the definitive treaty in

Paris.

See G. H. Guttridge, *David Hartley, M.P.* (Univ. of California Press, 1926. With bibliography.)

HARTLEY, JONATHAN SCOTT (1845-1912), American sculptor, was born at Albany, N.Y., on Sept. 23, 1845. He was a pupil of E. D. Palmer, New York, and of the schools of the Royal Academy, London; he later studied for a year in Berlin and for a year in Paris. He devoted himself particularly to the making of portrait busts, in which he attained high rank. Among his works are a statue of Miles Morgan, the Puritan, for Springfield (Mass.); the Daguerre monument in Washington; "Thomas K. Beecher," Elmira (N.Y.); "Alfred, the Great," Appellate Court-house, New York; "Young Hopi Stick Thrower" (1911); and "The Cradle of Pan" (1912). He died in New York city on Dec. 6, 1912.

HARTLIB, SAMUEL (c. 1599-c. 1670), English writer on education and agriculturist, was born towards the close of the 16th century at Elbing in Prussia, his father being a refugee merchant from Poland. His mother was the daughter of a rich English merchant of Danzig. About 1628 Hartlib went to England, where he carried on a mercantile agency. An enthusiastic admirer of Comenius, he published in 1637 his *Conatium Comenianorum praeludia*, and in 1639 *Comenii pansophiae prodromus et didactica dissertatio*. In 1641 appeared his *Relation of that which hath been lately attempted to procure Ecclesiastical Peace among Protestants*, and *A Description of Macaria*, containing his ideas of what a model State should be. During the Civil War Hartlib devoted himself to agriculture, publishing various works by himself, and printing at his own expense several treatises by others on the subject. In 1652 he issued a second edition of the *Discourse of Flanders Husbandry* by Sir Richard Weston (1645); and in 1651 *Samuel Hartlib, his Legacy, or an Enlargement of the Discourse of Husbandry used in Brabant and Flanders*, by Robert Child. For his various labours Hartlib received a pension from Cromwell, as he had spent all his fortune on his experiments. He planned a school for the sons of gentlemen, to be conducted on new principles, and this probably was the occasion of his friend Milton's *Tractate on Education*, addressed to him in 1644, and of Sir William Petty's *Two Letters* on the same subject, in 1647 and 1648. At the Restoration Hartlib lost his pension. Apparently he is referred to by Andrew Marvell as alive in 1670 and fleeing to Holland from his creditors.

See H. Dircks, *A Biographical Memoir of Samuel Hartlib* (1865).

HARTMANN, JOHANNES FRANZ (1865-), German astronomer, was born at Erfurt on Jan. 11, 1865. From 1886-91 he studied mathematics in Tübingen, Berlin and Leipzig. In 1891 he was appointed assistant in Leipzig observatory. In 1909 he became professor of astronomy and director of the observatory in Göttingen, and in 1921 director of the university observatory at La Plata, Argentine. He has worked on spectrographs and dispersion-curves and has written numerous papers on his spectral observations. He edited the volume on astronomy in the series *Die Kultur der Gegenwart* (1921). Hartmann invented the microphotometer (1899), and the spectrocomparator (1904). With Plaskett and Otto Struve, he discovered and investigated the calcium clouds in space.

HARTMANN, KARL ROBERT EDUARD VON (1842-1906), German philosopher, was born in Berlin on Feb. 23, 1842. He was educated for the army, but turned to philosophy, and in 1867 the university of Rostock conferred on him the degree of D. Phil. He subsequently returned to Berlin, and died at Grosslichterfelde on June 5, 1906. Von Hartmann's reputation was established by his first book, *The Philosophy of the Unconscious* (1869; 11th ed. 1904). Its success was due to the diversity of its contents (von Hartmann professing to obtain his speculative results by the methods of inductive science, and using many concrete illustrations), the fashionableness of its pessimism and the vigour and lucidity of its style. The Unconscious appears as a combination of the metaphysic of Hegel with that of Schopenhauer. It is both Reason and Will and the absolute all-embracing ground of all existence, the spiritual principle required by nature. Von Hartmann thus combines "pantheism" with "panlogism" in

a manner adumbrated by Schelling in his "positive philosophy." At the Fall, Will and Reason were separated, and the former, as blind impulse, determines the melancholy career of the Unconscious in the world process. Reason is in constant strife against Will and only when it is emancipated from this strife in the conscious reason of the enlightened pessimist can the world be redeemed. When the greater part of the Will in existence is so far enlightened by reason as to perceive the inevitable misery of existence, a collective effort to will non-existence will be made, and the world will relapse into nothingness, the Unconscious into quiescence. Civilization, like the happiness of the individual, means the annulment of the will-to-live and the gradual releasing of the Unconscious from its sufferings. Meanwhile we must provisionally affirm life and devote ourselves to social evolution, instead of striving after a happiness which is impossible; in so doing we shall find that morality renders life less unhappy. Suicide, and all other forms of selfishness, are highly reprehensible.

Von Hartmann's works number about thirty of which the chief are: *Kategorienlehre* (1896); *Das sittliche Bewusstsein* (1879); *Die Philosophie des Schönen* (1887); *Die Philosophie des Unbewussten* (1869) (3 vols., which now include his, originally anonymous, self-criticism, *Das Unbewusste vom Standpunkte der Physiologie und Descendenztheorie*, (and its refutation, Eng. trs. by E. C. Coupland, 1884); *Grundriss der Erkenntnislehre* (1907); *Das Problem des Lebens Biologische Studien* (1908); *Das religiöse Bewusstsein der Menschheit* (1881); *Geschichte der Metaphysik* (2 vols., 1899); *Kant's Erkenntnistheorie*; studies of Schelling, Lotze, von Kirchmann; *Zur Geschichte des Pessimismus* (1880); *Neukantianismus, Schopenhauerismus, Hegelianismus* (1877); *Moderne Psychologie* (1901); *Das Christentum des neuen Testaments* (1905); *Soziale Kernfragen* (1894); *Moderne Probleme* (1886); *Zwei Jahrzehnte deutscher Politik* (1888). His select works have been published in 10 volumes (2nd ed., 1885-96). See R. Köber, *Das philosophische System E. von Hartmanns* (1884); O. Plümacher, *Der Kampf ums Unbewusste* (2nd ed., 1890); A. Drews, *E. von Hartmanns Philosophie und der Materialismus in der modernen Kultur* (1890) and *E. von Hartmanns philosophisches System* (1906); O. Braun, *E. von Hartmann* (1909); N. E. Pohorilles, *Entwicklung und Kritik der Erkenntnislehre E. v. Hartmanns* (Vienna, 1911); G. S. Hall, *Founders of Modern Psychology* (1912); J. P. Steffs, *E. von Hartmanns Religions philosophie* (1921); C. O. Petraschek, *Die Logik des Unbewussten* (Munich, 1926). Full bibliography in Überweg, *Grund. der Gesch. der Phil.* pt. 4 (1923).

HARTMANN, MORITZ (1821-1872), German poet and patriot, of Jewish origin, was born at Duschnik, Bohemia, on Oct. 15, 1821. For two volumes of patriotic poems, *Kelch und Schwert* (1845) and *Neuere Gedichte* (1846), published at Leipzig, he was imprisoned by the Austrian authorities, but was released at the revolution in March 1848, and sat in the Frankfurt parliament. He took part in the revolution in Vienna, and after its suppression escaped to London and Paris. In 1849 he published *Reimchronik des Pfaffen Mauritius*, a satirical political poem in the style of Heine. During the Crimean War (1854-56) Hartmann was correspondent of the *Kölnische Zeitung*, settled in 1860 in Geneva as a teacher of German literature and history, became in 1865 editor of the *Freya* in Stuttgart and in 1868 a member of the staff of the *Neue Freie Presse* in Vienna. He died at Oberdöbling near Vienna on May 13, 1872.

Among Hartmann's works may be especially mentioned *Der Krieg um den Wald* (1850), a novel, the scene of which is laid in Bohemia; *Erzählungen eines Unsteten* (1858); and *Die Letzten Tage eines Königs* (1867); an idyll, *Adam und Eva* (1851), and a collection of poetical tales, *Schatten* (1851).

See O. Wittner, *Moritz Hartmann's Leben und Werke* (2 vols., 1907).

HARTMANN VON AUE (1170?-1210?), Middle High German poet, belonged to the lower nobility of Swabia. He became retainer of a nobleman whose domain, Aue, has been identified with Obernau on the Neckar, and took part in the Crusade of 1196-97. He is mentioned by Gottfried von Strassburg (c. 1210) as still alive, and in the *Krone* of Heinrich von dem Türlin, written c. 1220, he is mourned for as dead. Hartmann was the author of four narrative poems. The oldest of these, *Erec*, which may have been written as early as 1191, and the latest and ripest, *Iwein*, belong to the Arthurian cycle and are based on epics by Chrétien de Troyes (q.v.); between them lie the romance, *Gregorius*, also an adaptation of a French epic, and *Der arme Heinrich*, a charming specimen of mediaeval German poetry. The theme of the

latter is the cure of the leper, Heinrich, by a young girl who is willing to sacrifice her life for him. Hartmann's language is carefully chosen, his narrative lucid, flowing and characterized by a sense of balance and proportion which is rarely to be found in German mediaeval poetry. His lyrics, which are all fervidly religious, relate in some cases to the crusade.

Erec has been edited by M. Haupt (2nd ed., Leipzig, 1871); *Gregorius*, by H. Paul (2nd ed., Halle, 1900); *Der arme Heinrich*, by W. Wackernagel and W. Toischer (Basel, 1885) and by H. Paul (2nd ed., Halle, 1893); by J. G. Robertson (London, 1895), with English notes; *Iwein*, by G. F. Benecke and K. Lachmann (4th ed., Berlin, 1877) and E. Henrici (Halle, 1891-93). A convenient edition of all Hartmann's poems by F. Bech, 3 vols. (3rd ed., Leipzig, 1891-93, vol. 3 in 4th ed., 1902).

The literature on Hartmann is extensive. See L. Schmid, *Des Minnesingers Hartmann von Aue Stand, Heimat und Geschlecht* (Tübingen, 1874); H. Röttken, *Die epische Kunst Heinrichs von Veldeke und Hartmanns von Aue* (Halle, 1887); F. Saran, *Hartmann von Aue als Lyriker* (Halle, 1889); A. E. Schönbach, *Über Hartmann von Aue* (Graz, 1894); F. Piquet, *Étude sur Hartmann d'Aue* (Paris, 1898). Translations have been made into modern German of all Hartmann's poems, while *Der arme Heinrich* has repeatedly attracted the attention of modern poets, both English (Longfellow, Rossetti) and German (notably, Gerhart Hauptmann). See H. Tardel, *Der arme Heinrich in der neueren Dichtung* (Berlin, 1905).

HARTSHORN, SPIRITS OF, a name signifying originally the ammoniacal liquor obtained by the distillation of horn shavings, afterwards applied to the partially purified similar products of the action of heat on nitrogenous animal matter generally, and now popularly used to designate the aqueous solution of ammonia (*q.v.*).

HART'S-TONGUE (*Phyllitis*), the name given to a genus of ferns, formerly known as *Scolopendrium*, meaning "like a centipede," from the numerous lines of fructification on the leaves. *P. Scolopendrium* (*S. vulgare*) is common in Europe, including Great Britain, and extends into Asia and North America, but is very rare in the latter continent, occurring only locally in central New York, Tennessee, Ontario and New Brunswick. The thick, leathery, glossy fronds reach a length of 18 in. There are ten species of *Phyllitis*, mainly tropical and subtropical. (See FERN; PTERIDOPHYTES.)

HARTY, SIR HERBERT HAMILTON (1879-), Irish conductor and composer, was born at Hillsborough, Co. Down, Ireland, on Dec. 4, 1879. He was an organist in Belfast and in Dublin before he came to London in 1900. As an accompanist he was soon in great demand and his compositions also received recognition. His *Comedy Overture* was played at a promenade concert at Queen's Hall in 1907 and in the same year his *Ode to a Nightingale* was produced at the Cardiff festival with Madame Agnes Nicholls, his wife, in the solo part. In 1920, after gaining considerable experience by conducting the London Symphony orchestra, he was appointed permanent conductor of the Halle orchestra in Manchester. In 1925 he was knighted, and also received the degree of Mus.D. from Dublin university. In January 1927 he visited London with the Halle orchestra and chorus and gave a notable performance of Berlioz's *Requiem* at a British Broadcasting Corporation's Albert Hall concert. His compositions include a violin concerto; *With the Wild Geese*, tone poem for orchestra; *The Mystic Trumpeter* for voices and orchestra; an "Irish" symphony; a transcription of Handel's *Water-Music* for modern orchestra; songs and settings of folk-songs.

HĀRŪN AL-RASHID (hā-rōon' ar rah' shēd) (763-809), fifth of the 'Abbasids of Baghdad, and second son of the third caliph Mahdi, was born at Rai (Rhagae), and at the age of 22 ascended the throne. For the campaigns in which he took part prior to his accession see CALIPHATE: *The Abbasids*. He owed his succession to the prudence of Yahyā b. Khālid the Barmecide, his secretary, whom on his accession he appointed his lieutenant and grand vizier (see BARMECIDES). Under his guidance the empire flourished in spite of revolts in the provinces by the old Alid family. Successful wars were waged with the rulers of Byzantium and the Khazars. In 803, however, Hārūn became suspicious of the Barmecides, whom with a single exception he caused to be executed. Henceforward the chief power was exercised by Fadl b. Rabi', who had been chamberlain under Hārūn himself and

under his predecessors, Mansūr, Madhi and Hādī. Later troubles in the eastern parts of the empire, led Hārūn to go to Khorasan, but he died at Tus in March 809.

The reign of Hārūn (see CALIPHATE) was one of the most brilliant in the annals of the caliphate, in spite of losses in north-west Africa and Transoxiana. His fame spread to the West, and Charlemagne and he exchanged gifts and compliments as masters respectively of the West and the East. Himself a scholar and poet, Hārūn patronized poets, jurists, grammarians, cadis, scribes and musicians. The excellent administration of the empire during his life was in reality due to his viziers Yahyā and Fadl. Hārūn is known to Western readers as the hero of stories in the *Arabian Nights*; and in Arabic literature he is the figure of numberless anecdotes.

See the Arabic histories of Ibn al-Athir and Ibn Khaldūn; W. Muir, *The Caliphate* (1891); R. D. Osborn, *Islam under the Khalifs of Bagdad* (1878); G. Weil, *Geschichte der Chalifen* (Mannheim and Stuttgart, 1846-62); G. le Strange, *Bagdad during the Abbasid Caliphate* (Oxford, 1900); A. Müller, *Der Islam*, vol. i. (1885); E. H. Palmer, *The Caliph Haroun Alraschid* (1880); J. B. Bury's edition of Gibbon's *Decline and Fall* (1898), vol. vi.

HARUSPICES, Etruscan diviners, "entrail observers" (*cf.* Skt. *hira*, Gr. *χορδή*). Their art (*disciplina*) consisted especially in deducing the will of the gods from the appearance presented by the entrails of the slain victim. They also interpreted all portents or unusual phenomena of nature, especially thunder and lightning, and prescribed the expiatory ceremonies after such events. This formed a most complicated pseudo-science, in sharp contrast to native Italian divination, which consisted of asking the approval of the gods for a proposed action and deducing a "yes" or "no" from such omens as the flight of birds (see AUGURS, OMEN), and in simple inspection of the entrails of a victim to see if the beast were normal and therefore acceptable. The Etruscans were said to have learned it from a being named Tages (*q.v.*). Instructions were contained in certain books called *libri haruspiciani fulgurales, rituales*. The art was practised in Rome chiefly by Etruscans, occasionally by native-born Romans who had studied in the priestly schools of Etruria. Though of great importance under the early republic, it never became a part of the state religion. In this respect the haruspices contrast with the augurs, who were an ancient and purely Roman institution, and were a most important element in the political organization of the city. In later times the art fell into disrepute (Cic. *de div.* ii. 24). Under the empire, however, we hear of a collegium of sixty haruspices; but this was never a state priesthood but a body of salaried expert advisers.

HARVARD UNIVERSITY, the oldest and one of the foremost of American educational institutions, situated chiefly in Cambridge, Mass., but also in Boston and other places. In 1636 the general court of the Colony voted £400 towards "a schoale or colledge," which in the next year was ordered to be at "Newetowne." In memory of the English university where many (probably some 70) of the leading men of the Colony had been educated, the township was named Cambridge in 1638. In the same year John Harvard (1607-38), an immigrant Puritan minister to America, a bachelor and master of arts of Emmanuel college, Cambridge, dying in Charlestown, Mass., bequeathed to the wilderness seminary £780 (half his estate) and 260 books; and the college, until then unorganized, was named Harvard college (1639) in his honour.

The history of Harvard is unbroken from 1640, and its first commencement was held in 1642. The spirit of the founders is beautifully expressed in the words taken from *New England's First Fruits* (1643) and carved on the college gates: "After God had carried us safe to *New-England*, and wee had builded our houses, provided necessities for our liveli-hood, rear'd convenient places for Gods worship and settled the Civill Government; One of the next things we longed for, and looked after was to advance *Learning* and perpetuate it to Posterity; dreading to leave an

illiterate Ministry to the Churches, when our present Ministers shall lie in the Dust." The charter of 1650 dedicated the college to "the advancement of all good literature, arts, and sciences," and "the education of the English and Indian youth . . . in knowledge and godlyness." The second building (1654) on the college grounds was called the "Indian College." In it was set up the college press, which since 1638 had been in the president's

BY COURTESY OF MASSACHUSETTS HISTORICAL SOCIETY

HARVARD COLLEGE IN 1726, AFTER A CONTEMPORARY ENGRAVING
On the right is Massachusetts Hall, added in 1720 to the group of three buildings then composing the college, and the only one of them which remains to the present date. It is now used as a dormitory

house, and here, it is believed, was printed the translation of the Bible (1661-63) by John Eliot into the language of the natives, with his primer, catechisms, grammars, tracts, etc. A fair number of Indians were students, but only one, Caleb Cheeshahteumuck, took a bachelor's degree (1665). By generous aid received from abroad for this special object, the college was greatly helped in its infancy.

The charter of 1650 has been in the main, and uninterruptedly since 1707, the fundamental source of authority in administration. It created a self-perpetuating corporation consisting of the president, the treasurer and five fellows, who formally initiate administrative measures, control the college funds, and appoint officers of instruction and government, subject, however, to confirmation by the board of overseers (established in 1642), which has a revisory power over all acts of the corporation. Circumstances gradually necessitated ordinary government by the resident teachers; and to-day the various faculties, elaborately organized, exercise immediate government and discipline over all the students. The board of overseers was at first jointly representative of State and Church. The former, as founder and patron, long regarded Harvard as a State institution; but the controversies and embarrassments incident to legislative action proved prejudicial to the best interests of the college, and an act of 1865 severed the connection with the State. Financial aid and practical dependence had ceased some time earlier; indeed, from the very beginning, and with steadily increasing preponderance, Harvard has been sustained and fostered by private munificence. The last direct subsidy from the State terminated in 1824, although State aid was afterwards given to the Agassiz museum, later united with the university.

The church was naturally sponsor for the early college. The changing composition of its board of overseers marked its liberation first from clerical and later from political control; since 1865 the board has been chosen by the alumni who therefore really control the university. When in the first half of the 17th century the unity of Puritanism, in religion and in politics, gave way to a variety of intense sectarianisms, this, as also the incoming of Anglican churchmen, made the old faith of the college insecure. The conservatives, who clung to pristine and undiluted Calvinism, sought to entrench themselves in the board of overseers. The history of the college from about 1673 to 1725 was exceedingly troubled. One episode in the struggle was the foundation of Yale college by the conservatives of New England as a truer "school of the prophets" after they had failed to secure control of the government of Harvard. In 1792 the first layman was chosen

to the corporation; in 1805 a Unitarian became professor of theology; in 1843 the board of overseers was opened to clergymen of all denominations; in 1886 attendance on prayers ceased to be compulsory. Thus Harvard, in response to changing conditions, grew away from the ideas of its founders.

Harvard, her alumni and her faculty had been very closely connected with American letters, not only in the colonial period, when the Mathers, Samuel Sewall and Thomas Prince were important names, and in the revolutionary and early national epoch with the Adamses, Fisher Ames and Robert Treat Paine, but especially in the second third of the 19th century, when the great New England movements of Unitarianism and Transcendentalism were led by Harvard graduates. In 1805 Henry Ware was elected the first anti-Trinitarian to be Hollis professor of divinity, and this marked Harvard's close connection with Unitarianism, in the later history of which nearly all the leaders were Harvard graduates. Of the "Transcendentalists," Emerson, Francis Henry Hedge, Clarke, Convers Francis, Parker, Thoreau and Christopher Pearse Cranch were Harvard graduates. Longfellow's professorship at Harvard in 1836-54 identified him with it; Oliver Wendell Holmes was professor of anatomy and physiology at Harvard in 1847-82; and Lowell, a Harvard alumnus, was Longfellow's successor in 1855-86 as professor of the French and Spanish languages and literatures. Ticknor and Charles Eliot Norton, in literary criticism, are other important names. The historians Sparks, Bancroft, Hildreth, Palfrey, Prescott, Motley, Parkman and Fiske were graduates of Harvard, as were the orators Edward Everett, Charles Sumner and Wendell Phillips.

In organization and scope of effort Harvard became, especially after 1869, under the direction of President Charles W. Eliot, in the highest sense a university; but the "college" proper, whose end is the liberal culture of undergraduates, continues to be the centre of university life, as it is the embodiment of university traditions. The medical school (in Boston) dates from 1782, the law school from 1817, the divinity school (though instruction in theology was of course given from the foundation of the college) from 1819, and the dental school (in Boston) from 1867. The Bussey institution (at Jamaica Plain) was established in 1871 as an undergraduate school of agriculture, and reorganized in 1908 for advanced instruction and research in subjects relating to agriculture and horticulture. The Graduate School of Arts and Sciences dates from 1872, and the Graduate School of Business Administration from 1908. The latter is situated just across the Charles river from the college and is housed in a series of suitable buildings erected in 1926-27 through the generous gift of \$6,000,000.00 from Mr. George F. Baker of New York. The Lawrence scientific school, established in 1847, was practically abolished in 1907-08 but was re-established later as the Harvard engineering school, and comprises departments of study in mechanical, electrical, civil, sanitary, municipal and mining engineering, in sanitary and industrial chemistry and in metallurgy. There are also schools of public health, of architecture, of landscape architecture, and the Graduate School of Education to which alone of the various departments women are admitted. The university institutions include the botanic garden (1807) and the (Asa) Gray herbarium (1864); the Arnold arboretum (1872) at Jamaica Plain for the study of arboriculture, forestry and dendrology; the university museum, founded in 1859 by Louis Agassiz as a museum of comparative zoology, greatly developed by his son, Alexander Agassiz, and transferred to the university in 1876, though under an independent faculty; the Peabody museum of American archaeology and ethnology, founded in 1866 by George Peabody; the Fogg art museum (1895); the Semitic museum (1889); the Germanic museum (1902), containing rich gifts from Kaiser Wilhelm II., the Swiss Government and individuals and societies of Germanic lands; the astronomical observatory (1843, location 42° 22' 48" N. lat., 71° 8' W. long.), which long maintained a station near Arequipa, Peru, but removed in 1927 to a point near Bloemfontein, South Africa; besides a number of other museums and laboratories. A permanent summer engineering camp is maintained at Squam lake, New Hampshire. In Petersham, Mass., is the Harvard Forest, about 2,000 ac. of hilly wooded country; this

forest was given to the university in 1907, and is an important part of the equipment of the division of forestry.

The Harvard library is the largest university library in the country, and is of exceptional value. In 1928 it numbered, including the various special and departmental libraries, 2,785,000 books and pamphlets. Some of its collections are of great value from associations or special richness. There are department libraries connected with the law school, the Arnold arboretum, the Gray herbarium, the Bussey institution, the astronomical observatory, the meteorological observatory, the Peabody museum, the museum of comparative zoology and the schools of theology, medicine, dentistry, engineering, business administration, architecture, landscape architecture and education. In 1878 the library published the first of a valuable series of *Bibliographical Contributions*. Other publications of the university include, for example, the *Harvard Oriental Series* (started 1891), *Harvard Studies in Classical Philology* (1890), *Harvard Theological Review* (1907), *Harvard Law Review* (1889), *Harvard Historical Studies* (1897), *Harvard Economic Studies* (1906), *Harvard Psychological Studies* (1903), *Harvard Engineering Journal* (1902), the *Bulletin* (1874) of the Bussey institution, the *Archaeological and Ethnological Papers* (1888) of the Peabody museum, and the *Bulletin* (1863), *Contributions and Memoirs* (1865) of the museum of comparative zoology. The *Harvard Alumni Bulletin*, a weekly, and the *Harvard Graduates' Magazine* (1892), a quarterly, are published chiefly for the alumni.

In 1927-28 there were 1,311 officers of instruction and 10,748 students (1,059 in 1869), the latter including 3,250 in the college, 4,775 in the graduate and professional schools, 415 in graduate medical courses and 2,844 in the summer school, but with 536 deducted from the total "for names counted more than once." The whole number of degrees conferred in 1928 was 2,126. The average age of the students at entrance, only 14 years so late as 1820, had risen in 1890 to 19 years, making possible the transition to a régime of great liberty of life and studies with positive improvement to the morals of the student body. A strong development toward the university ideal marked the last half of the 19th century, especially in the widening of courses, the betterment of instruction and the progress in university freedom. The elimination of the last vestiges of sectarianism and churchly discipline, a lessening of oversight of conduct, a lopping off of various outgrown colonial customs, a complete reconstruction of professional standards and methods, the development of a great graduate school in arts and sciences based on and organically connected with the undergraduate college, a marked improvement in the college standard of scholarship, the allowance of great freedom to students in the shaping of their college course (the "elective" system), and very remarkable material prosperity marked the administration (1869-1909) of President Eliot.

In the co-ordination in the curricula of American colleges of the elements of professional training and liberal culture Harvard has been bold in experiment and innovation. She took a leading part in the movement that transformed university education, and her influence upon secondary education in America has been great. Her entrance requirements to the college and to the schools of medicine, law, dentistry and divinity have been higher than those of other American universities. A bachelor's degree is requisite for entrance to the professional schools (except that of dentistry), and the master's degree (since 1872) is given to students only for graduate work in residence, and rarely to other persons as an honorary degree. In scholarship and in the growth of academic freedom Germany gave the quickening impulse. This influence began with George Ticknor and Edward Everett, who were trained in Germany, and was continued by several eminent German scholars, some driven into exile for their liberalism, who became professors in the second half of the 19th century, and above all by the many members of the faculty later trained in German universities.

The ideas of recognizing special students and introducing the elective system were suggested in 1824, attaining establishment even for freshmen by 1885, the movement characterizing particularly the years 1865-85. The basis of the elective system is freedom in choice of studies within liberal limits. This freedom was

modified in 1910 by requiring each student to choose enough courses in one field to enable him to gain considerable knowledge of that subject, and by distributing a certain number of courses among other fundamental subjects so as to secure a more well-rounded education. At the same time the "degree with distinction" was established for high attainment in general, coupled with distinguished success in the subject to which the student had given most attention. Beginning with 1916, general final examinations on the student's field of concentration were introduced for all students in the departments of history, government and economics; the plan was later extended to almost all departments.

In the years following 1916 a system of tutors was developed to direct the private reading of the students. The tutor meets his men individually each week and advises as to their private study; he is in no sense a coach. The results thus far show that the tutorial system is of great educational value; it encourages the student to think of his chief subject as a whole, and to read independently in his field, while the general final examination gives an opportunity to test his capacity at the end of his course. The two have resulted in increased interest on the part of the students and in higher scholarship among students of varying abilities.

The material equipment of Harvard is very rich. The total investments were valued June 30, 1928, at \$94,372,702.22. For the fiscal year ended on that day, the total income of the university, excluding gifts to capital account and gifts for immediate use given in that year, was \$10,489,889.40. Gifts in the year were, for capital account, \$4,462,349.11; for immediate use, \$1,809,906.67. In the year (1927-28) the amount distributed in scholarships, fellowships, prizes and other aids to students was \$461,723.02. Among the university buildings are residence halls, dining halls, libraries, laboratories, museums, a theatre for public ceremonies, a chapel, a home for religious societies, a club-home (the Harvard Union) for graduates and undergraduates, an infirmary, a gymnasium, boat-houses and a concrete stadium capable of seating 54,000 spectators.

RADCLIFFE COLLEGE, an institution of higher education for women, dates from the beginning of instruction of women by members of the Harvard faculty in 1879, the Society for the Collegiate Instruction of Women being formally organised in 1882. The present name was adopted in 1894, in honour of Ann Radcliffe, Lady Mowson (*ob. c. 1661*), widow of Sir Thomas Mowson, alderman and (1634) lord mayor of London; she was the founder (1643) of the first scholarship in Harvard college. From 1894 also dates the present official connection of Radcliffe with Harvard. The requirements for admission and for degrees are the same as in Harvard, and all diplomas are countersigned by an authorized official of Harvard and bear the university seal. Instruction is given by members of the university teaching force, who repeat in Radcliffe many Harvard courses. Many advanced courses in Harvard, and to a certain extent laboratory facilities, are directly accessible to Radcliffe students, and they have unrestricted access to the library.

HARVEST, the season of the ingathering of crops (A.S. *haerfest* "autumn," O.H. Ger. *herbist*). Harvest has been a season of rejoicing from the remotest ages. The Romans had their Cerealia or feasts in honour of Ceres. The Druids celebrated their harvest on Nov. 1. In pre-Reformation England Lammas Day (Aug. 1, O.S.) was observed as the beginning of the harvest festival. Throughout the world harvest has always been the occasion for many queer customs which all have their origin in the animistic belief in the corn-spirit or corn-mother. This per-

sonification of the crops has left its impress upon the harvest customs of modern Europe. In West Russia, for example, the figure made out of the last sheaf of corn is called the bastard, and a boy is wrapped up in it. The woman who binds this sheaf represents the "corn-mother," and an elaborate simulation of childbirth takes place, the boy in the sheaf squalling like a newborn child, and being, on his liberation, wrapped in swaddling bands. Even in England vestiges of sympathetic magic can be detected. In Northumberland, an image formed of a wheat sheaf, and dressed in a white frock and coloured ribbons, is hoisted on a pole. This is the "kern-baby" or harvest-queen, and is set up in a prominent place during the harvest supper. In Scotland, the last sheaf, if cut before Hallowmas, is called the "maiden," and the youngest girl in the harvest-field is given the privilege of cutting it.

Throughout the world, as Sir J. G. Frazer shows, the semi-worship of the last sheaf is or has been the great feature of the harvest-home. Among harvest customs none is more interesting than harvest cries; the Devonshire reapers go through a ceremony which in its main features is a counterpart of pagan worship. "After the wheat is cut they . . . pick out a bundle of the best ears . . . ; this bundle is called 'the neck'; the harvest hands then stand round in a ring, an old man holding 'the neck' in the centre. At a signal from him they take off their hats, then all together they utter in a prolonged cry 'the neck!' three times, raising themselves upright with their hats held above their heads. Then they change their cry to 'Wee yen! way yen!' or, as some report, 'we haven!'" On a fine, still autumn evening "crying the neck" has a wonderful effect at a distance.

For a very full discussion of harvest customs see Sir J. G. Frazer, *The Golden Bough*.

HARVEST-BUG, the familiar name for mites of the family *Trombididae*, belonging to the order Acari of the class Arachnida. Harvest-bugs are the six-legged larval forms of several British species of *Trombidium*. They are minute, rusty-brown organisms, barely visible to the naked eye, which swarm in grass and low herbage in the summer and early autumn, and cause considerable irritation by piercing the skin, often lodging themselves in some part where the clothing is tight. They may be destroyed, and the irritation allayed, by rubbing the affected area with some insecticide like turpentine or benzene. They are not permanently parasitic, and if left alone will leave their temporary host to assume the active life characteristic of the adult mite, which preys upon minute animal organisms.

HARVESTER, **HARVESTER-SPIDER** or **HARVEST-MAN**, names given to Arachnids of the order Opiliones, referable to various species of the family Phalangidae. Harvest-spiders or harvest-men, so-called on account of their abundance in the late summer and early autumn, may be distinguished from all true spiders by the extreme length and thinness of their legs, and by the small size and spherical or oval shape of the body, which is not divided into two regions by a constriction. They may be met with in a great variety of situations. They are predacious, feeding upon small insects, mites, and spiders. The males are smaller than the females, and often differ markedly from them. The male is furnished with a long protrusible penis. The sexes pair in the autumn, and the female, by means of her long, protrusible ovipositor, lays her eggs in some cleft or hole in the soil. After breeding, the parents die. The eggs hatch with the warmth of spring. The adults are provided with a pair of glands, situated one on each side of the carapace, which secrete an evil-smelling fluid believed to be protective. Harvest-men are very widely distributed and are abundant in temperate countries of the northern hemisphere. They are also common in India. The long legs of harvest-men serve them not only as organs of rapid locomotion, but also as props to raise the body well off the ground, thus enabling the animals to stalk unmolested from the midst of an army of raiding ants. Harvester is sometimes, but erroneously, used as a synonym for harvest-bug (*q.v.*). (See ARACHNIDA.)

HARVESTING MACHINERY. The three principal types of crop for the harvesting of which machinery is employed are (a) grass, (b) cereals and (c) roots. Mechanical methods are to some

extent applied in the harvesting of other crops, *e.g.*, flax: but the principal food crops are those which chiefly lend themselves to mechanical treatment. In many parts of the world primitive methods are still, however, employed, and a very substantial part of the world's harvest is cut with the sickle and threshed out with a flail or by means of a sledge drawn round and round by oxen on a circular threshing floor. Whether machinery is to be employed or not depends chiefly upon land tenure: in a country of peasant holdings, few individuals can employ machinery economically and the common organization of labour which might permit the introduction of a machine is difficult. Weather, too, plays a large part in determining to what extent machinery may be used. The scythe, for example, is still employed habitually in certain hilly districts even in Great Britain, for mowing grass and the hand rake for turning it. Again, crops of cereals may be so badly laid that they cannot be cut mechanically and resort must be had to the scythe. Increasing attention is being paid to methods of drying crops artificially, and these are described elsewhere (see CROP-DRYING).
